EDITORIAL PREFACE

IF it had not been for the World War, there would not have been any occasion, so early as 1922, for a Supplement to the Eleventh Edition of the *Encyclopædia Britannica*, as published in 1911. But for the exceptional situation so created, the original intention not to take in hand anything equivalent to a Twelfth Edition until a much later date would undoubtedly have been maintained.

So colossal a convulsion, however, as that of the war, with consequences shown in so many unexpected directions and radically changing the world-outlook under the new conditions, made the need for this prompt addition to universal history absolutely imperative, as a record and illumination of so peculiarly dark and complex a period. The gap between 1911 and 1921 is all the more noticeable because, from the middle of 1914 onwards, authentic history could not be written at all, as had been practicable normally under earlier peace conditions, in such periodical publications as have usually served the requirements of the public for purposes of reference on contemporary affairs. The very nature of the war, and of the war conditions which persisted even after the Armistice, not only involved the imposition of secrecy, the cutting off of intercommunication, and even an interested perversion of fact in much that was given out for belief, but also led to a state of paralysis and aphasia in the spheres where, before the war, independent observation and judgment were to be found. Attention was monopolized everywhere by conditions of urgency and emergency, and concentrated upon the immediate conduct of life, while almost every expert, whether in scholarship or in science, was living, so to speak, from hand to mouth, with his accustomed intellectual activities interrupted, suspended, or diverted.

In such circumstances there arose inevitably a clear call for the publication of a Supplement to the *Encyclopædia Britannica* at as early a date as was practicable after the war, conformably with the arrival of a stage in post-war reconstruction which would once more enable its Editor to secure a reasonable modicum of the disinterested international coöperation on which the value of the *Encyclopædia Britannica*, as a critical record of world-history, has so long depended.

These New Volumes of the *Encyclopædia Britannica* accordingly follow precedents established during the 154 years since it made its first appearance in 1768. Between its Third (1788-97) and Fourth (1801-10) Editions, a two-volume Supplement (1801) to the Third Edition was published; and while the Fifth Edition (1815-7, a reprint of the Fourth) was still current, and the reëdited Sixth (1823-4) was nearly ready for issue, a "Supplement to the Fourth, Fifth and Sixth Editions," edited by Macvey Napier, appeared in six volumes during 1816-24. In 1902 again, by way of supplement to the Ninth Edition (1875-89), there were published eleven New Volumes, forming in combination with it the Tenth Edition, for the general editorship of which the present writer, taking over the task early in 1900 from the late Sir Donald Mackenzie Wallace, was responsible. Incidentally

those eleven New Volumes set a new precedent in publications of this kind by being prepared and issued simultaneously, and the same method was subsequently adopted in the preparation of the Eleventh Edition (1911).

Had it not been for the war, the twenty years between the average date of the Ninth Edition (25 Volumes, 1875-89) and the date of its supplementary New Volumes, which were added to form the Tenth Edition (1902), may be regarded as indicating the length of interval which might well have been expected to follow the publication of the Eleventh Edition before it in turn had a supplement added to it, to form in combination with it the Twelfth Edition. The course now taken, however, is directly in line with Macvey Napier's great Supplement (1816-24) to the Fourth, Fifth and Sixth Editions. The extent of that Supplement exhibited, indeed, a notable advance in the whole standard of the *Britannica* as a work of original scholarship and expert authority—the result of the copyrights having recently passed into the hands of the enterprising publisher Constable: but its interest in this particular connexion lies in the fact that it was conceived as a response to the pressing demand for a comprehensive survey of the situation resulting from the Great War which had just ended at Waterloo in 1815. In 1816, when the first volume of Macvey Napier's Supplement appeared, the same need was felt for an authoritative record and reconsideration of the new developments during the convulsions of 1793-1815 as has arisen now in respect of the decade ending with 1921, and for very similar reasons. Anyone who still cares to examine that remarkable Supplement of 1816-24 will find that the ideals of public service in education set before themselves by Constable and Macvey Napier (as expressed by the latter in his Preface to the Sixth Volume) were identical with those which animate the *Encyclopædia Britannica* to-day. The present writer, having made this examination, with knowledge of the many difficulties of his own task a hundred years later (on the first subsequent occasion of an engrossing conflict having upset the world), is bound to testify to the admirable way in which, amid evidence of similar obstructions and complications, Macvey Napier carried out his scheme. His Supplementary Volumes, organized at the conclusion of the Great War of 1793-1815, formed the only critical and universal survey then available of the period just ended. They brought together a mass of valuable material which was afterwards incorporated in later editions; indeed much of this information, fresh from the sources, could only have been placed on record by being obtained at that time—a consideration which is encouraging to the Editor of the present New Volumes in regard to the permanent value of the material embodied in them also.

In one respect, possibly, Macvey Napier may appear to have had an advantage over the present Editor, or a somewhat easier task, in that he had eight years over which to spread the publication of his volumes—first issued in parts. But his successor a hundred years later is too conscious of the real advantage given to the public by immediate and simultaneous production, and indeed of the superior quality which such a work possesses when the whole of it has been under editorial control at one time, to take this superficial view. Having himself organized the production of these New Volumes within a single year—a year, moreover, characterized by post-war unrest and unsettlement—he may perhaps make this difference of method some excuse, however, for any imperfections in them which may be found in the light of later events or of knowledge undisclosed

while they were in the making.[1] The generous reader may pardon some incidental defects or omissions, in consideration of his having the use, practically at once, of the full Supplement, as complete as it could reasonably be made, and not having to wait several years for a succession of volumes with long intervals between them. In the latter case each volume would be apt to exasperate him by cross-references from its articles to others in a volume still inaccessible; each earlier one, furthermore, would become relatively out-of-date as soon as the next one appeared; and the whole must lack organic unity, because the subject-matter, as distributed in one volume or another, must necessarily have been dealt with at different dates from dissimilar viewpoints.

These New Volumes, systematically arranged, in accordance with the traditional standards of the *Encyclopædia Britannica*, so that the articles may be adapted either for continuous reading or for occasional reference, have been planned as a guide to an appreciative understanding of contemporary affairs. The reader has before him what may be described as an international stock-taking, by carefully selected authorities, of the march of events all over the world from 1909–10 to 1920–1, and of the nature and critical value of such advances as were made in the principal branches of knowledge during that period. In this respect the New Volumes aim at giving a key to the problems of to-day, so far as these contemporary problems are bound up—as indeed they are to an unprecedented extent—with the new social and economic issues which only began to emerge in their present magnitude, or to impress themselves on the public, as the result of the tremendous upheaval caused by the World War. Yet it is necessary, in the interests of a publication which is essentially educational, to add one proviso. It remains as true as ever that contemporary human life and interests are organically related not only to the immediate developments of one preceding decade but to those of a succession of earlier decades and epochs, back to the abysses of time. The great Drama is of the Ages, and can only be appreciated with all its Acts on record. *The eye which looks only at the passing scene is too often colour-blind.* The roots of the Post-War World go down into the Pre-War World. Its proper interpretation can be found only in the light of all that earlier history on which we can look back—as we cannot do on contemporary affairs—with assurance that it is seen in perspective and in ordered values, as the result of an accumulation of disinterested criticism. The Post-War World is the residuary legatee of the Pre-War World, from which it inherits the whole basis of its intellectual equipment. The present survey of recent happenings, indispensable though it may be as an account of the Post-War World, can only therefore be utilized perfectly when it is regarded as an integral part of the unitary library of education represented in all the thirty-two volumes now forming the complete Twelfth Edition. The structure of that great edifice, with its contents, is not substantially affected by the fact that it has been built with an Annexe for housing more recent

[1] It may be noted here that, though bibliographical references, representing a selection of the most authoritative books or documents published since 1910, are plentifully made in the New Volumes, it was impossible, merely by way of supplement to the bibliographies attached to articles in the Eleventh Edition, to include them systematically, except in appropriate cases where this course was demanded by the nature of the supplementary articles. No attempt has been made when otherwise there was no substantial reason for adding a supplementary article at all to the account given of a subject in the Eleventh Edition, to add a list of later books published about it. Nor, indeed, in the Editor's judgment, would it have been in accordance with the objects of the *Britannica* to give the *cachet* of "authority" in this way to many contemporary publications which can hardly be said to have earned that title. The bibliographical references in the *Britannica* are especially valuable as *critically* directing the reader to the best sources, outside its own articles, for more detailed information; but the very nature of many of the articles in the New Volumes, as being the latest (or even the only available) authoritative accounts of purely contemporary developments, made it unnecessary—if indeed it would not be misleading—to direct the reader to comparatively ephemeral publications by less responsible writers.

acquisitions, in the shape of these New Volumes. They are designed as having behind or beside them the main body of the work—the earlier Volumes of the Eleventh Edition which were constructed in the closing years of the Pre-War World.

It may be pardonable for the present writer, at the end of the twenty-first year of his occupancy of the position of Editor of the *Encyclopædia Britannica*, to emphasize in retrospect one specially valuable characteristic of the Eleventh Edition, in supplying to-day an authoritative digest of world history and the progress of knowledge up to the last few months before it was originally published in 1911. Its value does not merely depend on the benefit secured to the reader of these New Volumes by its having also been produced as a whole at one date, so that its accounts of every subject, organically distributed under appropriate headings, represent uniformly a single editorial policy (identical with that of to-day), a common terminus of time in the facts dealt with, and a common standard of criticism in the viewpoints of its contributors—so far as expert opinion at any one moment is ever in agreement. This in itself is, no doubt, a great convenience in the linking up of the later information provided in the New Volumes.[1] But there is a still more important quality attaching to the Eleventh Edition, of which indeed its Editor was not himself fully aware during the critical years of its preparation. It required the experience obtained during the gestation of these New Volumes to teach the Editor how much simpler a matter it is to create such a "Library of Education" when the world is at peace and is progressing normally, as it was in the years preceding 1911, than when, as recently, it is everywhere in convulsion, nobody being able to tell from week to week what he would be doing next, or where some new complication or even revolution, political, economic, industrial or scientific, might break out, to the upsetting of any attempt at orderly statement of the progress of events and the crystallization of opinion. Though it was not so realized at the time, it is now evident that the maximum service which the *Encyclopædia Britannica* could have performed for the public of to-day was the production of the Eleventh Edition in 1911, before the war of 1914–9 cut a Grand Canyon gash in the whole intellectual structure of the world. For what would have happened if the complete new edition which would follow the Tenth Edition had not been undertaken until several years later—say, after the Armistice? In that case it would still have been necessary, in some way, to keep what may roughly be divided as the Pre-War and Post-War Worlds distinct. The account of the Post-War World would then substantially be what appears in the present New Volumes; for this must, in any case, start at a convenient point before the war, in order to make the break intelligible, and it must differ in scope and perspective from the part devoted to the Pre-War World, in proportion as its new problems require a different sort of discussion according to their bearing on the future rather than as continuations of past history. But so far as the Pre-War World is concerned—everything, that is to say, except the contemporary developments of the decade preceding 1921—it may be asserted, without fear of contradiction from anyone who can appreciate the responsibilities of an Editor of the *Encyclopædia Britannica*, that, if the task had not been undertaken till after 1914, it would have been absolutely impossible to produce to-day anything so comprehensively authoritative or critically complete as is actually available in the shape of the Eleventh Edition owing to its having been produced just before the war.

[1] Reference by volume and page (*e.g.* "*see* 2.403") is accordingly made, as a rule immediately after the headings of articles in the New Volumes (but also elsewhere in their course, as seemed useful), to places in the earlier volumes where accounts of the same subjects, leading up to the point where the account is now resumed, may be found.

In the present writer's judgment it is very remarkably the fact that, however carefully the contents of the Eleventh Edition are tested, as representing the highest standards of international research and criticism, whether in Science or in Art or in historical information, up to 1911, nothing substantial has occurred since to diminish its value or alter its perspective. The reason is that it was fortunately produced at a quiet period, when there was every opportunity for obtaining sure, authoritative and orderly surveys, in a world-society which was evolving along known lines of "normalcy"—to use President Harding's favourite expression—fairly calculable in advance in accordance with well-informed expectations, and permitting of a reasonably final judgment on the sequence of contemporary progress in relation to the past. To-day, on the other hand, the whole atmosphere of scholarship and thought has temporarily been vitiated by the world upheaval, and the coöperation enlisted for the Eleventh Edition is unattainable under present conditions. It is not too much to say that the service done by the *Encyclopædia Britannica* for the public, by bringing together in the Eleventh Edition its unique combination of the world's ripest judgments on every sort of subject, could not have been rendered to this generation at all if that Edition had not been completed before the war. As the composition of the present New Volumes shows, it has still been possible for the Editor to enlist the most highly qualified experts, and writers officially connected with Government Departments or Services, for dealing with matters familiar to them (and often known only to them) in the course of the past decade. But the writing of contemporary history by persons who have been chief agents or eye-witnesses is one thing; it is quite another to recreate the whole drama of the far-reaching past. To do that, as it was done in the Eleventh Edition, needs a type of mind and will which for the present has largely ceased to function along the pre-war ways.

Irrespectively, indeed, of the question whether as good a complete edition as the Eleventh could have been produced *de novo* now, it would cost in any case at least twice as much to make as it did in 1911, and it would have to be sold at a far higher price. But, from the editorial point of view, the important fact is that it could not be made to-day so as to have anything like the scholarly value of the work produced before the war by the contributors to the Eleventh Edition. Neither the minds nor the wills that are required for such an undertaking are any longer obtainable in any corresponding degree, nor probably can they be again for years to come. This is partly due to sheer "war-weariness," which has taken many forms. A shifting of interest has taken place among writers of the academic type, so that there is a disinclination to make the exertion needed for entering anew into their old subjects—a necessary condition for just that stimulating, vital presentation of old issues in the light of all the accumulated knowledge about them, which was so valuable a feature of the Eleventh Edition; the impulse has temporarily been stifled by the pressure of contemporary problems. Many of the pre-war authorities, moreover, have died without leaving any lineal successors, and others have aged disproportionately during the decade, while the younger generation has had its intellectual energies diverted by the war to work of a different order. Again (a most essential factor), it would have been impossible to attain the same full measure of international coöperation, among representatives of nations so recently in conflict, and in a world still divided in 1921 by the consequences of the war almost as seriously as while hostilities were actually raging.

It is with some satisfaction that the Editor has been able to make a fresh beginning in these New Volumes toward a revival of this coöperation, by including German, Austrian and Hungarian contributors, in addition to those from the countries allied or associated with the British Empire and the United States during the war. In the material structure of the New Volumes, and their sub-editing, the same note of Anglo-American solidarity is struck as in the Eleventh Edition; and this is again emphasized by their being dedicated jointly to the two Heads of the English-speaking peoples, by express permission of King George V. and President Harding. Nowhere except in Great Britain and the United States would it have been possible, under the world-conditions of 1921, to find the standard of poise and perspective required in their construction. Any other assumption, throughout these New Volumes, than that the terrible war of 1914–9 was won by those who had right and justice for their cause, would manifestly be impossible in the *Encyclopædia Britannica;* and historical justification for this belief is indeed given in the proper articles. On the other hand, many of the more violent criticisms of German action current during the war are now shown, in the Anglo-Saxon spirit of fair play, to have been exaggerated for "propaganda" purposes. Opinion on the incidents and issues of the war-period will probably continue to be revised by succeeding generations over and over again, as the weight of evidence, so much of it still undisclosed, increases; but a start is made here toward the acceptance of such conclusions as already represent a judicial view, expressed without favour or malice, free from any conscious bias, and backed by a presentation of the relevant facts on authority that is either admittedly unimpeachable or so far unchallenged. It was an integral part of the editorial policy to put aside any war-prejudice in inviting the assistance of contributors from among the nations which had fought against the Allies, so far as might be practicable without the intrusion of "propaganda," especially for narratives of the domestic history of the enemy countries, about which so little information had penetrated outside during the war-period. The list of writers of ex-enemy nationality, and of the articles contributed by them, shows that a considerable section of the contents, including the military history of the war itself (to which British, American, French, Italian, Belgian, German, and Austro-Hungarian soldiers have contributed), is derived from such sources; and this fact alone gives these Volumes a special interest. Consistently with this policy, the Editor has encountered only very rare disappointments in carrying out his plan of obtaining the best contributors available from all foreign countries, including Germany and Austria, in order to provide the most authoritative information on their own affairs according to their own respective standpoints. In this connexion it will be noted that, for the first time in the history of the *Britannica*, the article on Japan is contributed by a Japanese. The Editor is glad here to acknowledge the help of the distinguished historian, Prof. A. F. Pribram, of Vienna, in organizing, with the collaboration of Dr. Redlich, the eminent Austrian jurist, the whole series of articles dealing with Austro-Hungarian subjects. He had also the valuable assistance of Mr. George Saunders, formerly *The Times* correspondent in Berlin, in obtaining the coöperation of German contributors and in supervising the translation and editing of their articles; while Mr. George Adam, *The Times* correspondent in Paris during 1913–9, performed the same function in respect of France. In the case of Russia, the Editor was fortunately able to rely on the great authority of Sir Paul Vinogradoff. The Editor's thanks for useful advice

and assistance with regard to the articles on other foreign countries are due to President Masaryk (Czechoslovakia), Prof. H. Pirenne, Rector of Ghent University (Belgium), Prof. L. V. Birck of Copenhagen (Denmark), Mons. M. Beza, of the Rumanian Legation in London (Rumania), Mons. D. Caclamanos, the Greek Minister in London (Greece), Mons. H. N. Bronmer, of the Netherlands Legation in London (Holland), Baron Alströmer, the Swedish Chargé d'Affaires in London (Sweden), and Mons. Erik Colbran, of the League of Nations.

So many individuals have, in one way or another, smoothed the Editor's path, either by suggesting the best-qualified contributors or by giving helpful advice on the subject-matter of articles, that he can only make a rather arbitrary selection here in naming some of the more conspicuous. Practically every national Government, either directly or through its accredited representatives, has aided his attempt to give international authority to the New Volumes, by encouraging the use of its own sources of information; and British official coöperation, as also American, has been generously sanctioned and utilized. By the courtesy of the Naval Intelligence Department of the British Admiralty, the editorial staff had access to all the historical materials it had collected from various parts of the world for secret service during the war, including the handbooks of statistical and general information which had been privately printed by the Government for the use of British officers and political agents while the war was still in progress, and which were only partially "released" for publication afterwards. In this connexion acknowledgment may be made here, once for all, of the permission accorded by the Geographical Section of the British War Office (supplemented by that of the Controller of H.M. Stationery Office), and by the French *Service Géographique de l'Armée*, to reproduce British and French staff-maps, and also by the Librairie Militaire Berger-Lerrault, of Paris, to reproduce some of their maps of the battle areas. In different specialist spheres, the following acted as technical consultants: on Biology and Zoölogy, Dr. Chalmers Mitchell, secretary of the Zoölogical Society of London; on Botany, Prof. F. W. Keeble, of Oxford University; on Mathematics, Prof. G. H. Hardy, of Oxford University; on Aeronautics, Lt.-Col. Mervyn O'Gorman; on Medicine and Surgery, Dr. R. McNair Wilson; on Civil Engineering generally, Mr. H. M. Ross, editor of the *Times Engineering Supplement;* on Electrical Science and Engineering, Prof. J. A. Fleming, of University College, London. Each of the above was responsible for suggesting contributors on the subjects named, and assisted in coördinating their contributions. On military matters Maj. C. F. Atkinson acted for the Editor in obtaining the coöperation of a large number of expert advisers, at home and abroad, and he was responsible for organizing all the articles dealing with military history and equipment. On naval affairs useful advice was given by Rear-Adml. Sir W. Reginald Hall, M.P., and Rear-Adml. H. W. Richmond. Mr. Humbert Wolfe, of the British Ministry of Labour, and Mr. R. Page Arnot, of the unofficial Labour Research Department (the intelligence office of the British Labour movement), assisted, from different points of view, in planning the articles dealing with Labour developments, while valuable advice was received on their economic aspects from Sir Hubert Llewellyn Smith and Mr. Sidney Webb. The Editor's thanks are due to all these counsellors; and also to Lord Stamfordham, for material in connexion with the biographical article on King George V., to Sir Godfrey Thomas as regards that on the Prince of Wales, to Sir

Hercules Read for suggestions as to the treatment of Archaeology, and especially to Lord Justice Sir William Younger and Lord Newton, jointly and severally, for their help in securing the undertaking, by their colleague Sir Reginald Acland, K.C., of the article on "*Prisoners* of War," which represents the first judicial review of the evidence officially *taken by Sir William* Younger's committee on that subject.

In crediting the editorial staff as a whole with a loyal fellowship which alone rendered possible, by the coöperation of its various departments, the production of the New Volumes in so short a time from their inception, the Editor-in-chief must express his warmest acknowledgment of the services of the three principal assistant-editors in London—Dr. Henry Newton Dickson, D.Sc., formerly professor of Geography at University College, Reading, and Literary Director of the Naval Intelligence Department of the Admiralty during the war; Professor Walter Alison Phillips, Lecky Professor of Modern History at Trinity College, Dublin (who was able to follow up his previous association with the Eleventh Edition, as principal assistant-editor, by devoting his vacations, and such other time as he could spare, to this work); and Mrs. W. L. Courtney (Janet E. Hogarth), who, with an efficient lieutenant in Mrs. Guy Chapman, was in charge of the work done by the ladies who formed part of the staff. Apart from a general participation in headquarters control, Dr. Dickson was especially concerned with the subject-matter of geography and statistics, and with the selection of maps and illustrations, Prof. Alison Phillips with political and constitutional history, and Mrs. Courtney with the biographical articles and those dealing with the Women's Movement, and with the making of the Index, which thus supplements the Index to the Eleventh Edition under the same guiding hand which had been responsible for the great Index to the main body of the work. As Editor's Secretary, keeping touch with all departments, Mr. Arthur Bollaert Atkins also resumed his former rôle, with an efficiency which was invaluable to the editorial organization. The New York branch of the editorial staff, under Mr. Franklin H. Hooper, as American Editor, with Mr. H. R. Haxton and Dr. G. C. Scoggin as his principal assistants, acted in concert throughout with the London office, more particularly in arranging for articles by American contributors or dealing with American affairs. The Editor-in-chief was assured beforehand of the sympathetic and experienced collaboration he enjoyed in this respect by the fact that his editorial association with Mr. F. H. Hooper for such purposes had already been continuous since the year 1900. In seeing the New Volumes finally through the press, he had the advantage of having the combined force of the British and American editorial staffs brought to bear on the critical revision of the work as a whole.

As architect both of the Eleventh Edition and of the superstructure which now converts it into the Twelfth Edition, it has been the present writer's privilege to be served by an international company of practical builders, supplying the world's best available materials and masonry; and he has been inspired by the ambition of cementing and adorning, in the completed edifice, that great movement for Anglo-American coöperation, on whose progress from strength to strength the recovery of civilization after the World War of 1914–9 must so largely depend.

HUGH CHISHOLM.

Christmas 1921.

ABBREVIATIONS USED IN THESE VOLUMES

A

A.A. = Anti-Aircraft; Army Act (British); Automobile Association.
A.A.G. = Assistant Adjutant-General.
A.B.C. = Argentina, Brazil, Chile.
Abt. = *Abteilung* = Detachment, sub-unit (German Army).
ac. = acre or acres.
A.C. = *Artillerie de Campagne, Artillerie de Corps* = Field artillery, Corps artillery—followed by numeral (French).
A.C.I. = Army Council Instruction (British).
A.C. of S. = Assistant Chief-of-Staff (U.S.A.).
A.D. = *Anno Domini* = In the year of our Lord (Latin); *Artillerie divisionnaire* = Divisional artillery (followed by numeral) (French).
Adml. = Admiral.
A.E.F. = American Expeditionary Force.
A.F. = Air Force (British).
A.F.C. = Air Force Cross (British).
A.F.E.F. = Anglo-French Expeditionary Force.
A.F.M. = Air Force Medal (British).
A.F. of L. = American Federation of Labor.
A.G. = Adjutant-General.
A.I.D. = Aircraft Inspection Department (British).
A.I.F. = Australian Imperial Force.
A.L. = *Artillerie Lourde* = Heavy artillery (French).
Ala. = Alabama.
A.L.A.M. = Association of Licensed Automobile Manufacturers.
A.L.G.P. = *Artillerie Lourde à grande puissance* = Super-heavy artillery (French).
Als.-Lor. = Alsace-Lorraine.
A.L.V.F. = *Artillerie Lourde à voie ferrée* = Heavy railway artillery (French).
A.M.S. = Army Medical Service.
ANZAC. = Australian and New Zealand Army Corps.
A.O.C. = Army Ordnance Corps (since 1918 R.A.O.C.).
A.O.K. = *Armee-Oberkommando* = Supreme Army Command (Austro-Hungarian); Headquarters of an army, with numeral, *e.g.* A.O.K. 2 (German).
A.P.C. = Army Pay Corps; since 1918 R.A.P.C. (British).
A.P.D. = Army Pay Department (British).
Ariz. = Arizona.
Ark. = Arkansas.
A.S.C. = Army Service Corps; since 1918 R.A.S.C. (British).

C.-in-C. = Commander-in-Chief (British).
C.I.D. = Criminal Investigation Department (British).
C.I.G.S. = Chief of the Imperial General Staff (British).
C.M. = Court-martial.
C.M.B. = Central Midwives Board.
C.N. = *Comité Nationale de Secours et d'Alimentation* = National Committee for Relief and Feeding (Belgium).
co. = county.
Co. = Company.
C.O. = Commanding Officer (British).
C. of S. = Chief of Staff (U.S.A.).
Col. = Colonel.
Colo. = Colorado.
Comm. = Commander.
Conn. = Connecticut.
Corn. = Cornwall.
C.O.S. = Charity Organization Society (British).
C.P. = Centre-pivot (artillery).
C.R.A. = Commanding Royal Artillery, *i.e.* commanding a formation or station (British).
C.R.A. = *Commission régulatrice automobile* = Motor regulation staff (French).
C.R.B. = Commission for Relief in Belgium.
C.R.E. = Commanding Royal Engineers, *i.e.* commanding a formation (British).
C.r.h. / **C.r.o.** = Calibres-radius of head or ogive (artillery).
cub. ft. = cubic feet.
Cumb. = Cumberland.
C.W.S. = Coöperative Wholesale Society.
cwt. = hundredweight.

D

d. = died; also penny or pence.
D. = Director (*e.g.* D.M.O. = Director of Military Operations); as prefix of office-abbreviations = Deputy (*e.g.* D.D.M.I. = Deputy Director of Military Intelligence).
D.A. = *Détachement d'Armée* = Army group (French); Direct Action (fuze); *Direction de l'Arrière* = Directorate of the Rear Zone (French). Equivalent to British L. of C. and American S.O.S.
D.A.Q.M.G. = Deputy Assistant Quartermaster-General.
D.B.E. = Dame of the Order of the British Empire.
D.C. = *Division de Cavalerie* = Cavalry Division (French); District of Columbia.
D.C.A. = *Défenses Contre Avions* (or *Aéronefs*) = Anti-Aircraft Defence (French).

:.M. = Distinguished Conduct Medal (British).
. = Delaware.
t. = department.
:.S. = *Direction d'Étapes et de Services* = Directing staff of a line of communications of an army (French).
. = Devonshire.
.C. = Distinguished Flying Cross (British).
.M. = Distinguished Flying Medal (British).
. = Director-General (*e.g.* D.G. A.M.S. = Director-General Army Medical Service).
.V.O. = Director-General of Voluntary Organizations.
= *Division d'Infanterie* = Infantry Division (French).
:. = *Division d'Infanterie Coloniale* = Colonial Infantry Division (French).
. = Division.
p.Z. = *Doppelzünder* = Time and percussion fuze (German).
.R.A. = Defence of the Realm Act (British).
.R.E. = District Officer Royal Engineers (British).
set. = Dorsetshire.
.M.G. = Deputy Quartermaster-General.
. = *Division de Réserve* = Reserve Division (French).
.F. = Depression Rangefinder.
.C. = Distinguished Service Cross (U.S.A. and British).
.M. = Distinguished Service Medal (U.S.A. and British).
.O. = Distinguished Service Order (British).
:. = Durham.

E

. = East.
= Editor.
.F. = Egyptian Expeditionary Force.
= *exempli gratia* = for example (Latin).
.F. = Electro-motive force.
.E. = *Éléments non endivisionnés* = Troops not included in divisions ("corps troops" or "army troops") (French).
. = Essex.
h. = Esthonia.
seq. = *et sequentia* = and the following (Latin).

F

.N.Y.S. = First Aid Nursing Yeomanry Service (British).
KA. = *Fernkampfartillerie* = Super-heavy artillery (German).
= figure or figures (illustration).
. = Florida.
K. = *Flugabwehrkanone* = Anti-aircraft gun (German).
M. = Field Marshal; *Fusil Mitrailleur* = French light machine-gun.
M.L. = Field-Marshal-Lieutenant (Austro-Hungarian).
.b. = free on board.

fur. = furlong or furlongs.
F.W.D. = Four-wheel Drive.

G

"G" = General Staff branch of the Staff, and its functions (British).
G. = Gold.
Ga. = Georgia.
G.A. = *Groupe d'Armées* = Group of Armies (followed by E = *Est*, N = *Nord*, etc.) (French).
gal. = gallon or gallons.
Gal. = Galicia.
G.A.R. = Grand Army of the Republic (U.S.A.).
G.B.E. = Grand Cross of the Order of the British Empire.
G.d.A. = *General der Artillerie*
G.d.I. = *General der Infanterie*
G.d.K. = *General der Kavallerie* = "full" general (German and Austro-Hungarian).
Gen. = General.
G.H.Q. = General Headquarters (British and U S A.).
GI,GII,GIII. = Maintenance, Intelligence and Operation branches; General Staff (U.S.A.).
G.Kdo. = *General-Kommando* = Army corps headquarters (German).
Glos. = Gloucestershire.
G.M.T. = Greenwich Mean Time.
G.O. = *Generaloberst* = General in Command (German).
G.O.C. = General Officer Commanding (British).
Gov. = Governor.
G.Q.G. = *Grand Quartier-Général* = General Headquarters (French Field Armies).
gr. = gramme or grammes.
G.R. = *Gare régulatrice* = Regulating station—rail transport (French).
G.S. = General Staff (British and U.S.A.); General Service (British).
G.S.G.S. = Geographical Section General Staff (British).
G.S.O. = *Gas-Schutz Offizier* = Anti-gas Officer (German).
G.S.O.1,2,3 = General Staff Officer, 1st, 2nd and 3rd grade (British).
G.V.C. = *Gardes des Voies de Communication* = Line-of-Communication defence troops (French).

H

H. = *Honvéd* (as prefix in Austro-Hungarian designations); "*Heure*" = Zero hour, hour set for attack (French).
H.A. = Heavy Artillery; less frequently, horse artillery; high-angle (gun).
Hants. = Hampshire.
H.E. = High Explosive.
Hereford. = Herefordshire.
Herts. = Hertfordshire.
H.G. = *Heeresgruppe* = Group of armies (German).
hhd. = hogshead or hogsheads.
H.M.S. = His Majesty's Ship (British).
H.Q. = Headquarters (British and

Hunts. = Huntingdonshire.
H.T. = Horse Transport.
H.V. = High Velocity (gun).

I

I. = *Instantanée* = Instanta (in French fuze de tions); Island.
Ia. = Iowa.
i.A. = *im Auftrage* = By ord behalf of (German)
I.A. = Indian Army.
ib. *or* ibid. = *ibidem* = in the same (Latin).
I.D. = *Infanterie-Division* = try Division (Germ
i.e. = *id est* = that is (Latin)
I.H.P. = Indicated Horse-pow
Ill. = Illinois.
I.L.P. = Independent Labour (British).
in. = inch or inches.
in.² = square inches.
in.³ = cubic inches.
Ind. = Indiana.
Inf. = Infantry.
Is. = Islands.
I.W.W. = Industrial Workers World.

J

"J" = "*Jour*" = "Zero day' for attack (French)
J.C.A. = Jewish Colonization ciation.

K

K. = *Königlich* = Royal, or *serlich* = Imperial man).
Kan. = Kansas.
K.B.E. = Knight Commander Order of the Britis pire.
K.D. = *Kavallerie-Division* = ry Division (Germ
kgm. = kilogram or kilogram
K.K. = *Kaiserlich-Königlich* perial-Royal (Aus Landwehr).
km. = kilometre or kilometr
K.R. = King's Regulations (Army).
K.T.D. = *Kavallerie - Truppend* = Cavalry Div (Austro-Hungarian
K.u.K. = *Kaiserlich und Kōni* Imperial and Roya trianand Hungaria ignation of co army).
kw. = kilowatt or kilowatts.
Ky. = Kentucky.

L

L. = *Landwehr* (German Austrian).
La. = Louisiana.
Latv. = Latvia.
lb. = pound or pounds.
Lancs. = Lancashire.
L.C.C. = London County Cou
Ldst. = *Landsturm* (Austro-garian and Germ
Lith. = Lithuania.
L.M.G. = *Leichtes Maschinenge* Light machin (German).
L. of C. = Line of Communi

M

m. = mile or miles.

Maj. = Major.

Maj.-Gen. = Major-General.

Mass. = Massachusetts.

M.B.E. = Member of the Order of the British Empire.

M.C. = Military Cross (British); Master of Chemistry.

Md. = Maryland.

Mdx. = Middlesex.

Me. = Maine.

Mebu. = *Maschinengewehr-Eisenbeton-unterstand* = Reinforced concrete machine-gun emplacement (German).

M.E.F. = Mediterranean Expeditionary Force (British 1915–7).

Mesop. = Mesopotamia.

M.G. = Machine-gun (heavy implied, as a rule).

M.G.A. = Major-General in charge of administration, regional commands (British).

M.G.C. = Machine-gun Corps.

M.G.G.S. = Major-General, General Staff of an Army (British).

M.g.H. = *Mit geschränkter Haftung* = With limited liability (German).

M.G.K. = *Maschinengewehr-Kompanie* = Machine-gun Company (German).

M.G.O. = Master-General of the Ordnance (British).

M.I. = Military Intelligence; formerly also Mounted Infantry (British).

Mich. = Michigan.

Minn. = Minnesota.

Miss. = Mississippi.

M.L. = Muzzle-loading.

M.M. = Military Medal (British).

M. of M. = Ministry of Munitions (British).

Mo. = Missouri.

Mons. = Monmouthshire.

Mont. = Montana.

M.S. = Military Secretary.

M.T. = Mechanical Transport.

m.V. = *mit Verzögerung* = Delay-action fuze (German).

MW. = *Minenwerfer* = Trench Mortar (German).

N

N. = North.

N.A.C.B. = Navy and Army Canteen Board (British).

N.Af. = North Africa.

N.Am. = North America.

N.C. = North Carolina.

N.C.T. = Nitro-cellulose, Tubular.

N.D. = North Dakota.

Neb. = Nebraska.

Nev. = Nevada.

N.H. = New Hampshire.

N.H.P. = Nominal Horse-power.

N.I.D. = Naval Intelligence Division (British).

N.J. = New Jersey.

N.M. = New Mexico.

Nor. = Norway.

Norf. = Norfolk.

Northants. = Northamptonshire.

Northumb. = Northumberland.

N.O.T. = Netherlands Overseas Trust.

Notts. = Nottinghamshire.

N.S. = Gregorian, or new style, Calendar (*see* 4.994).

N.U.R. = National Union of Railwaymen (British).

N.U.S.E.C. = National Union of Societies for Equal Citizenship (British).

N.U.W.S.S. = National Union of Women's Suffrage Societies (British).

N.U.W.W. = National Union of Women Workers (British).

N.Y. = New York.

O

O. = Ohio.

O.B.E. = Officer of the Order of the British Empire.

O.C. = Officer Commanding (British).

O.H.L. = *Oberste Heeresleitung* = Supreme Army Command (German).

Okla. = Oklahoma.

Ore. = Oregon.

O.S. = Ordnance Survey (British); Julian, or old style, Calendar (*see* 4.994).

O.T.C. = Officers' Training Corps.

o.V. = *ohne Verzögerung* = Direct-action fuze (German).

Oxon. = Oxfordshire.

oz. = ounce or ounces.

P

P. = Percussion (fuze).

Pa. = Pennsylvania.

P.A. = *Pour ampliation* = Authorized for issue of documents (French Army).

P.C. = *Poste de Commandement* (French Army); Post of Command (U.S.A.) = battle or advanced headquarters (British).

P. et Cv. = *Parcs et Convois* = Trains and columns (French Army).

P.O. = *Par ordre* = By order; by command (French); Post Office.

Pol. = Poland.

pop. = population.

P.R. = *Poste-retard* = Delay-action fuze (French).

Pr. = Pounder (Gun designation).

Pres. = President.

Prof. = Professor.

pt. = pint or pints.

P.V. = *Pigeon voyageur* = Carrier-pigeon (French).

Q

Q.A.I.M.N.S. Queen Alexandra's Imperial Military Nursing Service (British).

Q.A.M.F.N.S. Queen Alexandra's Military Families Nursing Service (British).

Q.A.R.N.N.S. Queen Alexandra's Royal Naval Nursing Service (British).

Q.F. = Quickfiring (artillery).

Q.G. = *Quartier Général* = Headquarters (French).

Q.G.A2 = Headquarters of the II. Army (French).

Q.M.A.A.C. = Queen Mary's Army Auxiliary Corps (W.A.A.C.) (British).

Q.M.G. = Quartermaster-General.

Q.M.N.G. = Queen Mary's Needlework Guild (British).

qr. = quarter or quarters.

qt. = quart or quarts.

q.v. = *quod vide* = which see (Latin), for reference.

R

R. = Reserve (in troop designations).

R.A. = Royal Artillery (British).

R.A.C. = Royal Automobile Club (British).

R.A.F. = Royal Air Force (British).

R.A.M.C. = Royal Army Medical Corps (British).

R.A.O.C. = Royal Army Ordnance Corps (British).

R.A.S.C. = Royal Army Service Corps (British).

R.C.S. = Royal Corps of Signals, since 1919 (British).

R.D. = *Rive Droite* = Right bank (of a river) (French).

R.E. = Royal Engineers (British).

Regt. = Regiment.

Res. = Reserve.

R.F.A. = Royal Field Artillery (British).

R.F.C. = Royal Flying Corps (British).

R.G. = *Rive Gauche* = Left bank (of a river) (French).

R.G.A. = Royal Garrison Artillery (British).

R.H.A. = Royal Horse Artillery (British).

R.I. = Rhode Island.

R.I.B.A. = Royal Institute of British Architects.

R.I.C. = Royal Irish Constabulary.

R.M. = Royal Marines (British).

R.M.A. = Royal Military Academy (Woolwich); Royal Marine Artillery (British).

R.M.C. = Royal Military College (England).

R.M.L.I. = Royal Marine Light Infantry (British).

R.N. = Royal Navy (British).

R.N.A.F. = Royal Naval Air Force (British).

R.N.A.S. = Royal Naval Air Service (British).

R.N.R. = Royal Naval Reserve (British).

R.N.V.R. = Royal Naval Volunteer Reserve (British).

ro. = roods.

rs. = rupees.

R.O.D. = Railway Operating Division (British Army in France).

R.P. = Rules of Procedure (British Military Law).

R.T.O. = Railway Transport Officer (British and U.S.A.).

Rutl. = Rutland.

R.W. = Royal Warrant (for pay, etc.) (British).

S

S. = South.

s. = shilling or shillings.

S.A.E. = Society of Automobile Engineers.

Salop = Shropshire.

S.C. = South Carolina.

S.D. = South Dakota.

seq. = *sequens, sequentia* = the following (Latin).

Sil. = Silesia.

S.M.O. = Senior Medical Officer of a formation or station (British).

S.M.T.O. = Senior Mechanical Transport Officer of a formation (British).

Som. = Somersetshire.

S.O.S. = Services of Supply, Rear Zone (U.S.A.), equivalent to British L. of C.; also wireless call for life-saving.

S.P.R. = Society for Psychical Research.

S.P.V.D. = Society for Prevention of Venereal Disease.

Sq. = Squadron.

sq.ft. = square feet.

S.R. = *Sans retard* = Direct-action (of fuze).

S.S. = Secret Service.
S.S.F.A. = Soldiers' and Sailors' Families Association (British).
S.S.S.E. = *Société Suisse de Surveillance Économique* = Swiss Society for Economic Supervision.
Staffs. = Staffordshire.
Stellv. = *Stellvertreter, stellvertretend* = Substitute, acting deputy (German Army).
Suff. = Suffolk.
Sur. = Surrey.
Sus. = Sussex.

T

T. = Territorial (British Army)
T. = Time (fuze).
T.A. = Territorial Army (British, since 1919).
T.B.D. = Torpedo-boat destroyer.
T.C. = *Trains de Combat* = "Combat trains," "first-line transport" (French).
T.D. = Territorial Officers' Decoration (British).
Tenn. = Tennessee.
Tex. = Texas.
T.F. = Territorial Force (British, till 1919).
T.F.N.S. = Territorial Force Nursing Society (British).
T.M. = Trench Mortar.
T.M.G. = *Temps Moyen de Greenwich* = Greenwich Mean Time (French).
T.N.T. = Trinitrotoluene (High Explosive).
T.P.S. = *Télégraphie par le Sol* = Earth telegraphy (Power buzzer, etc.) (French).
T.S.F. = *Télégraphie sans fil* = Wireless telegraphy (French).

U

Ukr. = Ukraine.
U.S. = United States.
U.S.A. = United States of America; United States Army.
U.S.N. = United States Navy.
U.S.S. = United States Ship.

V

Va. = Virginia.
V.A.D. = Voluntary Aid Detachment; nursing service, Territorial Force (British).
V.C. = Victoria Cross (British).
V.D. = Volunteer Officers' Decoration (British).
Verst. = *Verstärkt* = Reinforced, chiefly of formations temporarily provided with artillery (German).
viz. = videlicet = namely.
Vt. = Vermont.
V.T.C. = Volunteer Training Corps (British).

W

W. = West.
W.A.A.C. = Women's Army Auxiliary Corps (Q.M.A.A.C.) (British).
W.A.F.F. = West Africa Frontier Force.
Wash. = Washington.
W.D. = War Department (British and U.S.A.).
Westm. = Westmorland.
Wilts. = Wiltshire.
Wis. = Wisconsin.
WM. = *Werfmine* = Shell of Minenwerfer (German).
W.O. = War Office (British Gov't.).
Worcs. = Worcestershire.
W.R.A.C. = Women's Reserve Ambulance Corps (British).
W.R.A.F. = Women's Royal Air Force (British).
W.R.N.S. = Women's Royal Naval Service (British).
W.S.P.U. = Women's Social and Political Union (British).
Wumba. = *Waffen- und Munitions-Beschaffungs-Amt* = War Office for Munitions (German).
W.U.S.L. = Women's United Service League (British).
W.Va. = West Virginia.
W.V.R. = Women's Volunteer Service.
Wyo. = Wyoming.

Y

yd. = yard or yards.
Y.M.C.A. = Young Men's Christian Association.
Yorks. = Yorkshire.
Y.W.C.A. = Young Women's Christian Association.

INITIALS USED IN VOLUME XXX. TO IDENTIFY CONTRIBUTORS,[1] WITH THE HEADINGS OF THE ARTICLES TO WHICH THESE INITIALS ARE SIGNED.

A. B.	ANTON BETTELHEIM, DR. JURIS.	**Austrian Empire:** *Literature and Drama.*
A. C. D.	ALFRED C. DEWAR, CAPT. R.N. (RET.), B.LITT. (Oxon.). Gold Medallist, Royal United Service Institution. Late of the Historical Section, Naval Staff, Admiralty.	**Admiralty Administration:** *British*; **Blockade; Convoy;** **Coronel; Dogger Bank.**
A. D. H.	SIR ALFRED DANIEL HALL, K.C.B., M.A., LL.D., F.R.S. Chief Scientific Adviser and Director-General of the Intelligence Department, Ministry of Agriculture and Fisheries. Author of *The Soil*; *Fertilisers and Manures*; *A Pilgrimage of British Farming*; *Agriculture after the War*; etc.	**Agriculture.**
A. E. Ev.	ARTHUR ERNEST EVEREST, D.Sc., PH.D., F.I.C. Joint-author of *The Natural Organic Colouring Matters* (Perkin and Everest). Author of various papers on Colouring Matters, etc., in *Proc. Roy. Soc.*, *Journ. Chem. Soc.*, etc.	**Botany:** *Chemistry of Sap Pigments of Plants.*
A. Fl.	ALEXANDER FLEMING, M.B., F.R.C.S. Director of the Department of Systematic Bacteriology in St. Mary's Hospital, London.	**Antiseptics.**
A. F. Pr.	ALFRED FRANCIS PRIBRAM, PH.D. Professor of Modern History in the University of Vienna. Member of the Vienna Academy of Science; etc.	**Aehrenthal;** **Austrian Empire:** *Austro-Hungarian Foreign Policy*; **Berchtold, Count L.;** **Burian, R. S. von;** **Charles (Emperor of Austria);** **Czernin, Count.**
A. G. L.	ALFRED GOODMAN LEVY, M.D., M.R.C.P. Physician to the City of London Hospital for Diseases of the Chest.	**Anaesthetics.**
A. G. W.	ADAM GOWANS WHYTE, B.Sc., A.I.E.E. Editor of the *Electrical Press Limited.* Author of *The Electrical Industry*; *Electricity in Locomotion*; *The All-Electric Age.*	**Electricity Supply:** *United Kingdom.*
A. H. Br.	ALFRED H. BROOKS, B.Sc., D.Sc. Geologist, U.S. Geological Survey. In charge of geologic and topographic surveys and investigations of mineral resources of Alaska. Vice-Chairman of the first Alaska Railroad Commission.	**Alaska.**
A. H. C.*	A. H. CHRISTIE. Late Director, Westminster Technical Institute.	**Arts and Crafts** (*in part*).
A. H. Ch.	ARTHUR HARRY CHURCH, M.A., D.Sc. University Lecturer in Botany, Oxford.	**Botany:** *General Morphology.*
A. H. Gi.	ARNOLD HARTLEY GIBSON, D.Sc., M.INST.C.E., M.I.MECH.E., F.R.AE.S. Professor of Engineering, University of Manchester; late Professor of Engineering, St. Andrews University. Member, Board of Trade Water Power Committee; Hon. Secretary, Conjoint Board, Water Power Committee. Member of the Air Ministry I.C.E. Committee. President, British Association, Section 9, 1921.	**Aeronautics:** *Aero-Engines.*

[1] *A complete list, showing all contributors to the New Volumes (arranged according to the alphabetical order of their surnames) with the articles signed by them, appears at the end of Volume XXXII.*

A. H. McM.	COLONEL SIR ARTHUR HENRY M'MAHON, G.C.M.G., G.C.V.O., K.C.I.E., C.S.I., F.S.A., F.L.S., etc. Foreign Secretary to the Government of India, 1911–4. British High Commissioner in Egypt, 1914–6. See biographical article: M'MAHON, SIR ARTHUR HENRY.	**Afghanistan.**
A. J. G.	REV. ALEXANDER JAMES GRIEVE, M.A., D.D. Principal and Professor of Systematic Theology in the Scottish Congregational College, Edinburgh. Assistant Editor of *Peake's Commentary on the Bible.*	**Church History:** *Free Churches: Presbyterian Church of Scotland.*
A. J. M.	SQUADRON LEADER ARNOLD JOHN MILEY, O.B.E., R.A.F. Design Branch, Directorate of Research, Air Ministry, in charge of Seaplane Development. Assistant Director, Air Department, Admiralty, June 1915 to June 1916; Senior Flying Officer Naval Air Station, Felixstowe, August 1916 to June 1917.	**Aeronautics:** *Seaplanes.*
A.-K.	GENERAL MORITZ AUFFENBERG-KOMAROW. See the biographical article: AUFFENBERG-KOMAROW, MORITZ.	**Army:** *Austro-Hungarian (in part);* **Beck, Graf von; Conrad von Hotzendorf.**
A. L. Bo.	ARTHUR LYON BOWLEY, Sc.D. Professor of Statistics in the University of London. Author of *Elements of Statistics; Wages in the United Kingdom;* etc.	**Cost of Living.**
A. L. C.	COLONEL ARTHUR LATHAM CONGER, U.S. ARMY. Distinguished Service Medal (U.S.A.), C.M.G. Legion of Honour. Formerly co-editor of *The Military Historian and Economist.*	**Army:** *United States;* **Champagne, Battles in** *(in part).*
A. P.	SIR ARTHUR PEARSON, BT., G.B.E. (died 1921). Chairman of the Blinded Soldiers and Sailors Care Committee. President of the National Institute for the Blind. Author of *Victory over Blindness; The Conquest of Blindness.* See the biographical article: PEARSON, SIR ARTHUR.	**Blindness.**
A. S. D.	AUGUSTUS SEISS DOWNING, A.B., M.A., L.H.D., LL.D. Assistant Commissioner for Higher Education and Director of Professional Education, University of the State of New York.	**Education:** *United States (in part).*
A. S. E.	ARTHUR STANLEY EDDINGTON, M.A., M.Sc., F.R.S. Plumian Professor of Astronomy and Experimental Philosophy and Director of the Observatory, Cambridge. Author of *Stellar Movements and the Structure of the Universe; Space, Time and Gravitation.*	**Astronomy.**
B. B.-H.	MAJOR-GENERAL BASIL FERGUSON BURNETT-HITCHCOCK, C.B., D.S.O., p.s.c. Director-General of Mobilization and Recruiting, War Office.	**Army:** *British.*
B. E. P.	GENERAL OF BRIGADE BARTHÉLEMY EDMOND PALAT. Late French Army. Commanded a Division 1915–6. Author of *La Grande Guerre sur le front Occidental; Les Batailles d'Artois et de Champagne;* and, under the pseudonym "Pierre Lebaut court," of *La Defense Nationale, 1870–1* and other works, including a general bibliography of 1870–1.	**Champagne, Battles in** *(in part).*
B. K. L.	BASIL KENNETH LONG. Editor of the *Cape Times.* Formerly Foreign Editor of *The Times.*	**Botha, General.**
B. W. D.	BRIAN WESTERDALE DOWNS, M.A. Fellow and Lecturer in Mediæval and Modern Languages and English, Christ's College, Cambridge.	**Cambridge.**
C. A. D.	CLYDE AUGUSTUS DUNIWAY, PH.D., LL.D. President of Colorado College, Colorado Springs, Colo. Author of *Freedom of the Press in Massachusetts.*	**Colorado.**
C. Br.	CARL BROCKHAUSEN, DR. JURIS. Professor of the Science of Administration in the University of Vienna.	**Austrian Empire** *(in part);* **Badeni, K.**
C. B. C.	WING COMMANDER T. R. CAVE-BROWNE-CAVE, C.B.E., R.A.F., F.R.AE.S., A.M.I.MECH.E., A.M.I.N.A. In charge of Airship Experiments and Research at the Admiralty and the Air Ministry. Lecturer in Airship Engineering, Imperial College of Science. Airship Member of the Aeronautical Research Committee. Formerly Engineer Officer, R.N. Airship Pilot, 1913. In charge of Non-rigid Airship Design and Construction at Kingsnorth, 1914–8.	**Aeronautics:** *Airships.*
C. C. H.	CHARLES CAESAR HAWKINS, M.A., M.I.E.E., ASSOC. AMERICAN I.E.E. Author of *The Dynamo.* Joint-author of *Papers on the Design of Alternate Current Machinery.*	**Electrical Engineering** *(in part).*
C. E. C.	MAJOR GENERAL SIR CHARLES EDWARD CALLWELL, K.C.B. Director of Military Operations, War Office, 1914–6. Author of *Small Wars; Military Operations and Maritime Preponderance; The Dardanelles;* etc.	**Dardanelles Campaign.**
C. E. W. B.	MAJOR CLAUDE EAGLES WILLOUGHBY BEDDOES, O.B.E. Gloucestershire Regiment. Inspector of Grenade Training, G.H.Q., Great Britain, 1915–8. Experimental Officer for Grenades and Trench Stores, Ministry of Munitions, 1915–9. Control Officer, Inter-Allied Commission of Control, 1919.	**Dogs, War** *(in part).*

C. F. A.	MAJOR CHARLES FRANCIS ATKINSON. T.D. Late East Surrey Regiment. Distinguished Service Medal (U.S.A.), Order of Saint Anne (Russia). Formerly Scholar of Queen's College, Oxford. Staff Officer for Trench Warfare Research, 1915–7. British Instructor in Intelligence, American Expeditionary Force, 1918. Editorial Staff of the 11th edition of the *Encyclopædia Britannica*. Author of *Grant's Campaigns*; *The Wilderness and Cold Harbor*; etc.	**Air Bombs** (*in part*); **Ammunition** (*in part*); **Army:** *Russian* (*in part*); *German*; **Artillery** (*in part*); **Balkan Wars** (*in part*); **Bombthrowers;** **Cordonnier, General;** **Eastern European Front Campaigns** (*in part*).
C. F. C.	CHARLES FREDERICK CROSS, B.Sc., F.R.S. Analytical and Consulting Chemist. Member of the firm of Cross & Bevan. Joint-author (with E. J. Bevan) of *Researches on Cellulose*; *Text-Book of Papermaking*.	**Cellulose.**
C. H. H.	CLARENCE HENRY HARING, B.LITT. (Oxon.), PH.D. (Harvard). Associate Professor of History in Yale University. Author of *The Buccaneers in the West Indies in the XVII. Century*; *Trade and Navigation between Spain and the Indies in the Time of the Habsburgs*; etc.	**Brazil.**

M. C. S.	MARIE CARMICHAEL STOPES, D.Sc. (Lond.), PH.D. (Munich). Fellow of University College, London. Sometime Lecturer in Palaeobotany, Universities of Manchester and London. Author of *Catalogue of Cretaceous Plants in the British Museum*, etc.	**Botany:** *Anatomy and Palaeobotany.*
M. Fl.	WING COMMANDER MARTIN FLACK, C.B.E., M.A., M.B. Director of Medical Research, Royal Air Force. Author of papers on the medical aspect of flying, etc.	**Aerotherapeutics.**
M. K.	DR. M. KRISTIANSEN.	**Denmark** (*in part*).
M. M. W.	MERTON M. WILNER. Editorial Writer on the *Buffalo Express*.	**Buffalo.**
M. O'G.	LIEUTENANT-COLONEL MERVYN O'GORMAN, C.B., D.Sc., M.INST.C.E. Formerly Superintendent of the Royal Aircraft Factory, Farnborough. Consultant to the Director-General of Military Aeronautics. Chairman of the Royal Aeronautical Society, and of the Accidents Investigation Committee of the Air Ministry.	**Aeronautics:** *Introductory.*
M. R.*	MAURICE RECLUS. *Conseiller d'État.* Colonial Editor of *Le Temps*.	**Algeria.**
M. St. L. S.	MAJOR AND BREVET COLONEL M. St. L. SIMON, C.B.E., R.E. Assistant Director, Engineering Services, Canada, 1908–10. Staff Captain, War Office (Fortifications and Works), 1911–5. Anti-Aircraft Defence Commander, London. 1916–8. Anti-Aircraft Defence, Independent Force, R.A.F., 1918. Anti-Aircraft Defence, Leeds, 1919. Commander of Northern Air Defences, 1919. General Staff, War Office, 1920–1.	**Air Defence.**
N. M. B.	NICHOLAS MURRAY BUTLER, PH.D., LL.D. (Cantab.), JUR.D., HON. D.LITT. (Oxon.). See the biographical article: BUTLER, N. M.	**Columbia University; Education:** *United States* (*in part*).
N. W.	NORMAN WILKINSON, O.B.E., R.I. Marine Painter and Etcher. Originator of Dazzle Painting (Naval Camouflage) as used by the Allied Powers in the World War. Author of *The Dardanelles*.	**Camouflage:** *Naval.*
O. Kr.	OTTO KRIEGK, PH.D. (Göttingen). Member of the Staff of the *Weser Zeitung*, Berlin Office.	**Bremen.**
O. L.-L.	OLIVER STILLINGFLEET LOCKER-LAMPSON, C.M.G., D.S.O., M.P., B.A. Parliamentary Secretary (Private) to Mr. Austen Chamberlain as Chancellor of the Exchequer and as Leader of The House of Commons. Author of *The Great Preference Debate*.	**Chamberlain, J. Austen.**
O. S.	OSKAR STARK. Member of the Berlin Staff of the *Frankfurter Zeitung*.	**Bavaria:** *Political History.*
O. v. K.	BARON OTTO VON KLIMBERG, DR. JURIS.	**Bosnia and Herzegovina.**
P. B.	PAUL BOURSON. Member of the Commissariat General of the French Republic at Strasbourg.	**Alsace-Lorraine.**
P. Vi.	SIR PAUL VINOGRADOFF, M.A., D.C.L., LL.D., DR. HIST., DR. JURIS. Corpus Professor of Jurisprudence, Oxford. Author of *Villainage in England*; *The Growth of the Manor*; *Outlines of Historical Jurisprudence*; etc. See the biographical article: VINOGRADOFF, SIR PAUL.	**Benckendorff, Count; Denikin, Anton.**

Ri.	RIGHT HON. LORD RIDDELL. Vice-Chairman of the Newspaper Proprietors' Association. Chairman of the Weekly Newspaper and Periodical Proprietors' Association. Represented the British Press at the Peace Conference, 1919–21. See the biographical article: RIDDELL, LORD.	**Censorship** (*in part*).
R. A. C.	RALPH ADAMS CRAM, LITT.D. (Princeton), LL.D. (Yale), F.R.G.S. Fellow of the American Institute of Architects and of the North British Academy of Arts. Hon. Corresponding Member of the Royal Institute of British Architects. Associate of the National Academy. Member of the American Institute of Arts and Letters. Supervising Architect, Princeton University. Lecturer on the Philosophy of Architecture, Massachusetts Institute of Technology. Member of the firm of Cram, Goodhue & Ferguson. Author of *Church Building*; *The Ruined Abbeys of Great Britain*; etc. See the biographical article: CRAM, RALPH ADAMS.	**Architecture**: *United States*.
R. B.-P.	LIEUTENANT-GENERAL SIR ROBERT BADEN-POWELL, BART., K.C.B., K.C.V.O., LL.D. Chief Scout.	**Boy Scouts**: *United Kingdom*.
R. DeC. W.	ROBERT DECOURCY WARD, A.M. Professor of Climatology, Harvard University. Author of *Climate Considered Especially in Relation to Man*.	**Climate and Climatology.**
R. F. T.	RICHARD F. TAYLOR, M.B.E., F.S.S. Statistician to the Ministry of Mines.	**Coal**: *United Kingdom*.
R. H. G.	RALPH HENRY GABRIEL, PH.D. Assistant Professor of History in Yale University. Author of *The Evolution of Long Island*, etc.	**Connecticut.**
R. K.	LIEUTENANT-COLONEL RUDOLF KISZLING. Late General Staff, Austro-Hungarian Army. Now of the Kriegsarchiv, Vienna.	**Eastern European Front Campaigns** (*in part*).
R. K. B.-W.	BRIGADIER-GENERAL RALPH KIRBY BAGNALL-WILD, C.M.G., C.B.E., R.A.F., M.I.MECH.E. Director of Aircraft Inspection. Fellow and Past Chairman of the Royal Aeronautical Society. Commission, Royal Engineers, 1893. Inspector of Aircraft, 1913.	**Aeronautics**: *Materials and Methods of Manufacture*.
R. K. H.	LIEUTENANT-COLONEL ROBERT KNOX HEZLET, C.B.E., D.S.O. Royal Field Artillery. Superintendent of External Ballistics, Ordnance Committee. Author of *Nomography*; *Interior Ballistics*; etc.	**Ballistics** (*in part*).
R. M. H.	SQUADRON LEADER R. M. HILL, R.A.F., M.C., A.F.C. Associate Fellow of the Royal Aeronautical Society. Formerly in charge of the Experimental Flying Department, Royal Aircraft Establishment. Author of paper to the Royal Aeronautical Society: *A Comparison of the Flying Qualities of Single- and Twin-Engined Aeroplanes*; Aeronautical Research Committee Reports and Memoranda No. 678; *The Influence of Military and Civil Requirements on the Flying Qualities of Aeroplanes*.	**Aeronautics**: *Performance of Aeroplanes*.
R. M. Wi.	R. MCNAIR WILSON, M.B., CH.B. Fellow of the Royal Society of Medicine. Editor, Oxford Medical Publications. Late Research Worker in Cardiology, Medical Research Committee. Consultant to the Ministry of Pensions in Trench Fever.	**Bilharziosis; Burns and Scalds; Cancer.**
R. McK. W.	RONALD MCKINNON WOOD, B.A. (Cantab.), A.M.I.C.E., F.R.AE.S. Head of Aerodynamics Department, Air Ministry.	**Aeronautics**: *Development of Aeroplane Design*.
R. N. R. B.	ROBERT N. RUDMOSE BROWN, D.Sc. Member of the Scottish National Antarctic Expedition, 1902–4, and of the Scottish Arctic Expeditions, 1909, 1912 and 1914. Lecturer in Geography, University of Sheffield. Author of *Spitsbergen*, etc. Joint-author of *The Voyage of the Scotia*.	**Åland Islands; Arctic Regions.**
R. P. D.	R. PALME DUTT. Late Scholar of Balliol College, Oxford. Author of *The Two Internationals*. Editor of *The Labour International Handbook*.	**Communism.**
R. Si.	ROBERT SIEGER, PH.D. Professor of Geography, University of Graz; Member of the Academy of Science, Vienna.	**Austria, Republic of**: *Introduction*; *Economic Conditions*.
R. Str.	RICHARD STRIEGL, DR. JURIS. Secretary of the Industrial District Commission.	**Austrian Empire**: *Economic Conditions* (*in part*).
R. Th.	RALPH THICKNESSE. Barrister-at-Law. Author of *Digest of Law*; *Husband and Wife*; etc.	**Children, Law Relating to**: *United Kingdom*; **Divorce**: *United Kingdom*.
R. T. T.	SIR REGINALD THOMAS TOWER, K.C.M.G., C.V.O. Administrator of Danzig and High Commissioner of the League of Nations, 1919–20.	**Danzig.**
R. van O.	CAPITAINE-COMMANDANT R. VAN OVERSTRAETEN. Aide-de-Camp to H. M. The King of the Belgians. Graduate of the Staff College. Order of Leopold. D.S.O. Legion of Honour.	**Antwerp**: *Siege of 1914*; **Army**: *Belgian*.

S. B. W.	S Williams. Assistant Managing Editor of *Electrical World*.	**Electricity Supply:** *United States.*
S. G. P.	\ey Gross Paine, D.Sc., F.I.C. Assistant Professor of Bacteriology, Imperial College of Science and Technology, London.	**Bacteriology:** *General and Agricultural.*
St. J. E.	John Greer Ervine. Dramatic Critic of *The Observer*. Author of *The Magnanimous Lover*; *Mixed Marriage*; *Jane Clegg*; and other plays.	**Drama.**
S. P. S.	ɪnley Parker Smith, D.Sc., M.I.E.E., A.M.I.C.E. Joint-author of *Papers on the Design of Alternate Current Machinery*.	**Electrical Engineering** (*in part*).
S. R. W.	v. Stacey R. Warburton, B.A. Editor of *Year Book of the Churches*. Secretary of Literature of the General Board of Promotion of the Northern Baptist Convention, U.S.A.	**Church History:** *United States.*
S. V.	ale Vincent, LL.D., D.Sc., M.D., F.R.S.E., F.R.S.C. Professor of Physiology in the University of London. Author of *Internal Secretion and the Ductless Glands*.	**Ductless Glands.**
T. C. McC.	iomas Chalmers McCorvey, M.A., LL.D. Professor of History and Political Science in the University of Alabama. Author of *The Government of the People of the State of Alabama*. Contributor to *The Library of Southern Literature* and *The South in the Building of the Nation*, etc.	**Alabama.**
T. G. M.	homas Garrigue Masaryk. President of the Czechoslovak Republic.	**Czechoslovakia.**
V. B.-J.	aptain Vivian Bulkeley-Johnson. Entered Rifle Brigade, 1913. Served in France, 1914–5. G.H.Q., 1916. Aide-de-Camp to Governor-General of Canada, 1916–8. Officer of the War Cabinet, 1918–9. Air Ministry, 1919–21.	**Aeronautics:** *Control of Air Traffic.*
V. H. B.	ernon Herbert Blackman, Sc.D., F.R.S. Professor of Plant Physiology and Pathology in the Imperial College of Science and Technology.	**Botany:** *General Physiology.*
V. L. E. C.	ɜeneral Victor Louis Émilien Cordonnier. See the biographical article: Cordonnier, V. L. E.	**Argonne, Battles of the; Army:** *French.*
W. A. P.	Valter Alison Phillips, M.A. (Oxford and Dublin). Lecky Professor of Modern History in the University of Dublin. Member of the Royal Irish Academy. Author of *Modern Europe*; *The Confederation of Europe*; etc.	**Diplomacy.**
W. B. A.	W. Broughton Alcock. Director Central Laboratory, Ministry of Pensions.	**Dysentery.**
W. F. S.	William F. Spalding, Cert.A.I.B., F.R.Econ.S. Examiner in Banking, Currency and Foreign Exchange to various public bodies. Author of *Foreign Exchange and Foreign Bills in Theory and in Practice*; *Eastern Exchange*; *Currency and Finance*; etc. Sometime Editor of the *Statist* British Banking Supplement and International Banking Supplement.	**Banking:** *British.*
W. G. C.	William George Constable, M.A. Fellow of St. John's College, Cambridge. Barrister-at-Law. Lecturer at the Wallace Collection.	**Beerbohm, Max; Besnard, P. A.**
W. G. Ma.	Major-General Sir William Grant Macpherson, K.G.M.G., C.B., LL.D. Editor-in-Chief of the *Medical History of the Great War*. Formerly Deputy Director-General, Army Medical Service. Author of *Handbooks of the Medical Services of Foreign Armies*, etc.	**Army Medical Service:** *British.*
W. G. S. A.	William George Stewart Adams, M.A. Gladstone Professor of Political Theory and Institutions in the University of Oxford.	**Education:** *United Kingdom.*
W. H. T.	Colonel W. H. Tschappat (U.S. Army). Author of *Ordnance Treatise*, U.S.A.	**Ammunition** (*in part*); **Ballistics** (*in part*).
W. J. C.*	W. J. Childs. Late of the Intelligence Department of the Admiralty (Geographical Section).	**Armenia; Azerbāijān; Cilicia.**
W. K. Mc(	William Kidston McClure, M.A. (Oxon). Late Correspondent of *The Times* in Rome. Correspondent of *The Times* on the Italian Front, 1915–7. Author of *Italy's Part in the War*; *Italy in North Africa*; Chapters on Italy in *The Times History of the War*; etc.	**Asiago, Battle of; Cadorna, General; Caneva, Carlo; Caporetto, Battle of.**
W. L. C.	Major Wallace L. Clay. Ordnance Department of the U.S. Army.	**Ammunition** (*in part*).
W. L. G*	William L. Griffith. Permanent Secretary, Office of the High Commissioner for Canada, London. Author of *The Dominion of Canada*; article on "Canada," *Oxford Survey of the British Empire*.	**Alberta; British Columbia; Canada.**

W. L. P.	WILLIAM LYON PHELPS, M.A., PH.D., LITT.D. Lampson Professor of English Literature at Yale University. Author of *Essays on Modern Novelists*; *Essays on Russian Novelists*; *Essays on Modern Dramatists*; *The Twentieth Century Theatre*; *The Advance of English Poetry*; etc.	**American Literature.**
W. P.	WOODFORD PATTERSON, B.A. Secretary of Cornell University.	**Cornell University.**
W. P. C.	WESTON P. CHAMBERLAIN. Colonel, Army Medical Corps, U.S. Army.	**Army Medical Service:** *United States.*
W. R. I.	WALTER RENTON INGALLS. Consulting Mining and Metallurgical Engineer, New York. Author of *Metallurgy of Zinc and Cadmium.*	**Copper.**
W. R. Ma.	WILLIAM R. MANNING, PH.D. Economist, Latin-American Division, U.S. Department of State. Author of *Nootka Sound Controversy* (Justin Winsor Prize Essay of American Historical Association, 1904); *Early Diplomatic Relations Between the United States and Mexico* (Albert Shaw Lectures, Johns Hopkins University, 1913); etc.	**Cuba.**
W. St.	WILLIAM STOCKING, M.A. (Yale). Newspaper Editor, 1865-1900. Historian and Statistician, Detroit Board of Commerce, 1903–21. Author of *Under the Oaks*; *History of the Republican Party*; etc.	**Detroit.**
W. S. Ro.	WILLIAM SPENCE ROBERTSON, PH.D. Professor of History in the University of Illinois. Author of *Francisco de Miranda and the Revolutionizing of Spanish America*; *Rise of the Spanish American Republics*; etc.	**Bolivia; Colombia; Ecuador.**
W. v. B.	WILHELM VON BLUME, DR. JURIS. Professor of Law in the University of Tübingen. Author of *Familienrecht des Bürgerlichen Gesetzbuchs*; *Erbrecht des Bürgerlichen Gesetzbuchs.* Coöperated in the drafting of the Constitution of Württemberg, 1919.	**Baden; Bavaria** (*in part*).
W. Wo.	LIEUTENANT-COLONEL WILLIAM WOOD, D.C.L., F.R.S. (Canada). Reserve of Officers, Canadian Army. Coördinating Officer of the Canadian Special Mission at the Naval and Military Fronts, 1917. Formerly President of English Section of Royal Society of Canada and of Historic Landmarks Association. Author of *The Fight for Canada*; *The Logs of the Conquest of Canada*; *Folk Songs of New France*; etc.	**Canada:** *Literature, French Canadian.*
X.	Initial used for anonymous contributors.	
Y. C.	YVES CHATAIGNEAU. American Distinguished Service Cross. Knight of the Legion of Honour. Lecturer in the University of Belgrade. Author of "*L'Émigration Vendéenne*," *Annales de Géographie*, 1917, "*La Yougo-Slavie*," *Annales de Géographie*, 1921.	**Balkan Peninsula** (*in part*)
Y. D.	GENERAL YOURI DANILOV.	**Army:** *Russian* (*in part*).

ENCYCLOPÆDIA BRITANNICA

VOLUME XXX

THE FIRST OF THE NEW VOLUMES

ABBE, CLEVELAND (1838–1916), American meteorologist, was born in New York Dec. 3 1838. He studied astronomy under Brünnow and B. A. Gould, and spent a year at the Pulkovo Observatory, 1865–6, under Struve. He was assistant at the U.S. Naval Observatory, 1867–8, and Director of the Cincinnati Observatory, 1863–73. His success there in forecasting the weather from meteorological observations telegraphed from various points led to his being called to the U.S. Signal Service in 1871. Thereafter with Government aid he was enabled to extend the field of his forecasts and became the "Father of the Weather Bureau." The bureau was formally established in 1891 under the Department of Agriculture, and Abbe remained its head until his death Oct. 28 1916. To his initiative is largely due the introduction of the system of standardized time.

He was the author of *Report on Standard Time* (1879); *Report on the Solar Eclipse of July 1879* (1881); *An Account of Progress in Meteorology and Allied Subjects in the Years 1879–81* (1883); *Treatise on Meteorological Apparatus and Methods* (1888); *Preliminary Studies in Storm and Weather Prediction* (1889); *Recent Progress in Dynamic Meteorology* (1890); *The Mechanics of the Earth's Atmosphere* (3 vols. of translations, 1891–1910); *The Physical Basis of Long-Range Forecasting* (1902); *The Progress of Science as Illustrated by the Development of Meteorology* (1908); *Notes on Balloons and on Waterspouts from the Voyage of La Pérouse* (1914) and *The Introduction of Meteorology into Courses of Instruction in Mathematics and Physics* (1915).

ABBEY, EDWIN AUSTIN (1852–1911), American painter (*see* 1.11), died in London, Aug. 1 1911. The last years of his life were devoted to mural paintings for the Capitol at Harrisburg, Pa., his native state. He completed "The Apotheosis of Pennsylvania," which stands behind the Speaker's chair in the House of Representatives, also "The 24 Hours" for the ceiling of the dome; but for the Senate chamber he finished only one painting — "Von Steuben Training the American Soldiers at Valley Forge." In 1910 there was completed under his supervision the decoration of the Peers' corridor of the Houses of Parliament. He left bequests of his works to the Metropolitan Museum of Art in New York, to the Boston Museum of Fine Arts and to the National Gallery in London. In 1912, the Old Masters' Exhibition of the Royal Academy, held at Burlington House, London, included over 300 works of Abbey's loaned for this special occasion as a memorial to him.

ABBOTT, LYMAN (1835–), American divine and author (*see* 1.26), continued after 1910 as editor of *The Outlook*, and in a less degree as a public speaker, to take an active part in the discussion of important public questions. After the outbreak of the World War he supported the cause of the Allies, and on the sinking of the "Lusitania" in 1915 urged that America break off diplomatic relations with Germany. He was the author of

The Spirit of Democracy (1910); *America in the Making* (1911, being the Yale lectures on the responsibilities of citizenship); *The Four Anchors* (1911); *Letters to an Unknown Friend* (1913); *Reminiscences* (1915, containing in the preface an admirable summary of his liberal views) and *The Twentieth Century Crusade* (1918).

'ABDUL HAMID II. (1842–1918), ex-Sultan of Turkey (*see* 1.35), died Feb. 10 1918. On his deposition in April 1909 he was sent to Salonika as a state prisoner, but when that town capitulated to the Greeks during the Balkan War (1912) he was brought back to Constantinople. In 1915 it was judged prudent to exile him from Turkey in Europe and he was removed to Smyrna.

ABERCORN, JAMES HAMILTON, 2nd Duke of (1838–1913), British politician (*see* 1.43), who served as High Constable of Ireland at the coronation of King George V. (1911), died in London Jan. 3 1913. He was succeeded as 3rd duke by his eldest son, *James Albert Edward Hamilton*, born Nov. 30 1869.

ABERCROMBIE, LASCELLES (1881–), English poet, was born at Ashton-upon-Mersey, Ches., Jan. 9 1881, and educated at Malvern and Victoria University, Manchester, where he studied science. His first work, *Interludes and Poems*, appeared in 1908, and his other works include: *Mary and the Bramble* (1910); *The Sale of St. Thomas* (1911); *Emblems of Love* (1912); *Deborah* (1912); *Speculative Dialogues* (1913) and *The Epic* (1914), besides a critical study of Thomas Hardy (1912). He was in 1919 appointed lecturer in Poetry at the university of Liverpool.

ABERDEEN AND TEMAIR, JOHN CAMPBELL GORDON, 1st Marquess of (1847–), British politician (*see* 1.47), retained his office as Lord-Lieutenant of Ireland until 1915. On his retirement he was created Marquess of Aberdeen and Temair, the latter title being a form of the place-name Tara, chosen for its connexion with the history of Ireland. His wife, Ishbel Maria (b. 1857)—daughter of Dudley Marjoribanks, 1st Baron Tweedmouth—whom he married in 1877, took a prominent part in charitable work during her residence in Ireland, becoming president of the Irish Industries Association and other societies. She did excellent work in increasing the number of nurses and establishing committees for the improvement of sanitary conditions and combating the spread of tuberculosis in Ireland. She published in 1908 *Ireland's Crusade against Tuberculosis*.

ABINGDON, WILLIAM LEPER [Pilgrim] (1859–1918), English actor, was born May 2 1859 at Towcester, Northants. He began life as a bank clerk, but soon went on the stage, first appearing at Belfast in 1881. His chief successes were in melodrama, with Wilson Barrett's travelling companies and later at the Adelphi theatre, London, where he played in *The Harbour Lights* (1889) and many similar pieces. Between 1903 and 1911

he appeared often in America. In 1905 he played Monks in *Oliver Twist* at His Majesty's theatre, London. He died in New York May 20 1918.

ABNEY, SIR WILLIAM DE WIVELESLIE (1843–1920), English chemist, was born at Derby July 24 1843 and educated at Rossall school, obtaining a commission in the R.E. 1861. In 1876 he became C.B., D.Sc., D.C.L. and F.R.S. and from 1893 to 1897 he was successively president of the Royal Astronomical Society and of the Physical Society. In 1899 he became assistant secretary to the Board of Education; in 1903 he was appointed advisor to the science department of the Board, and the same year became a member of the Advisory council for education to the War Office. In 1900 he was knighted and in 1904 became chairman of the Society of Arts. His contribution to science was mainly in the furtherance of photographic chemistry and especially of colour photography and colour printing (*see* 16.661; 21.489, 498, 531, 532; 25.631; 6.729). His publications on these subjects include *Instruction in Photography* (1870); *Colour Vision, Colour Measurement and Mixture* (1893); and *Trichromatic Theory of Colour* (1914). He also wrote *Thebes and its Five Great Temples* (1876), and, with C. D. Cunningham, *The Pioneers of the Alps* (1888). He died at Folkestone Dec. 3 1920.

ABRUZZI, DUKE OF THE [Luigi Amedeo] (1873–), Italian vice-admiral and explorer, son of Amedeo, late Duke of Aosta and sometime King of Spain, was born at Madrid Jan. 29 1873. He entered the navy as a cadet and followed a regular naval career in which he achieved great distinction; but he also became well known as an eminent traveller and mountaineer. He was the first to ascend Mt. St. Elias in Alaska (1897), and in 1899 he organized an expedition with the object of reaching the North Pole; although he himself was disabled by frostbite early in 1900 and forced to remain on his ship, the "Stella Polare," Comm. Cagni pushed on with a part of the expedition and reached the lat. of 86° 34′, at that time the record of northern exploration. In 1906 he was the first to ascend Mt. Ruwenzori in East Africa, reaching the twin summits (16,800 ft.), which he named Margherita and Alexandra, and also the other chief peaks of the range; he made the first detailed map of the Ruwenzori and collected much scientific information about it. In 1909 he explored the Central Karakoram in the Himalayas and by ascending peak K2 achieved the record for height; among other scientific work the expedition completed the map of the great Baltoro glacier. During the Libyan War he commanded a naval squadron in the Adriatic and had various successful engagements with Turkish warships. During the World War he was commander-in-chief of the Italian naval forces, and showed very high qualities of seamanship, strategy and organization in the extremely difficult operations in the Adriatic. He had British and French warships under his orders. He relinquished his command in 1917 owing to disagreements with Adml. Thaon di Revel, chief of the Naval Staff, and retired from the service. Afterwards he undertook an important colonization and agricultural development scheme in Italian Somaliland. He was made a Knight of the Order of the Annunziata.

ABYSSINIA (*see* 1.82).—Since 1910 boundary commissions have delimited in part the Sudan-Abyssinia and the Italian-Abyssinian frontier. No change was made in the international status of the country between 1910 and 1921. The conquests of Menelek had been retained and the independence of the empire maintained. The Spanish protectorates excepted, Abyssinia was the only country of Africa neutral throughout the World War.

Recent History.—From 1899, a year which marked the end of an era of conquest and civil war, the Emperor Menelek (*see* 18.128) had maintained internal peace and had cautiously encouraged commercial relations with Europeans. But in 1910 Menelek was stricken by a malady which incapacitated him from rule, although until his death, in Dec. 1913, and for years afterwards (*e.g.* in 1919), his name was invoked by the people as that of the highest authority in the country. A regency was formed in 1910, consisting of Lij Yasu—Menelek's grandson, whom he had nominated his heir in 1908—and Ras Tesamma, Lij Yasu being then only fourteen. Menelek's wife, the Empress Taïtu, a princess of Tigré, opposed the regency, called to her aid the Tigrian chiefs, and usurped authority. She refused to see the representatives of foreign powers and stopped the building of the railway from Jibuti (*see* 1.95) to the capital, Addis Abbaba. After maintaining her position about a year Taïtu was overthrown by a palace revolution. She took no further part in the government and died Feb. 11 1918.

Not long after the regency was established Ras Tesamma, a capable man of moderating influence, died, April 1911. Lij Yasu then attempted to reign uncontrolled. He was strongly opposed; but with the help of his father Ras Michael, chief of the Wollo Galla, Yasu made good his authority and on Menelek's death was acknowledged negus negusti (king of kings, emperor).

At that time, the beginning of 1914, the condition of the country was not without promise. The building of the railway from Jibuti had been resumed; in 1912 it had reached the Hawash river, and was then (1914) being carried up the steep escarpment to the Abyssinian plateau. Even in its incomplete state it carried in 1913 merchandise valued at over £1,600,000. A considerable trade between the Galla provinces (western Abyssinia) and the Sudan had also developed. Both Abyssinians and Gallas showed a distinct appreciation of foreign products; it needed only good government and the provision of better means of communication to have brought about a great development of the very rich natural resources of the country. Lij Yasu, however, was a youth of depraved morals, his administration was both weak and tyrannical, and the result was in the south anarchy,[1] and in the north the alienation of the Tigrians, always jealous of Shoa (Menelek's hereditary kingdom). The maintenance of a large standing army was another cause of poverty and discontent. Out of a total population, according to trustworthy estimates, of from 10,000,000 to 12,000,000, about 500,000 were in the army. (Detailed figures for 1916 gave a total of 571,000 as the strength of the Abyssinian forces.) In the Galla, Somali and Shankalla (*i.e.* negro) provinces these men lived largely by plunder.

Such was the situation when the World War broke out. Lij Yasu had already come very much under German and Turkish influence, the chief agent in the propaganda of the Central Powers having been Herr K. Schwemmer, consul for Austria-Hungary. (Schwemmer, owing to Italian pressure, was recalled to Vienna and left Abyssinia in Oct. 1914.) Yasu had already given offence to the Abyssinians, whose attachment to their own form of Christianity is strong, by his neglect of the observances of the national church, and in June 1914 had caused his father, Ras Michael, to be crowned negus (king) of Wollo, the only province of Abyssinia proper inhabited by Moslems (Galla intruders). Michael remained nominally a Christian; Yasu, at first secretly and later openly, embraced Islam, and, inspired by Turco-German policy, set himself to unite all the Moslems of the empire. He married the daughters of several Danakil and Galla chiefs, and betrothed himself to the daughter of Aba Jiffar, King of Jimma, the most powerful Moslem prince in the empire. He also made political alliances with Moslems outside the Abyssinian dominions, among others with the "Mad" Mullah of Somaliland, then at war with the British. His policy was summed up as (1) Moslem as opposed to Christianity; (2) Galla as opposed to Abyssinian; (3) Turco-German as opposed to the Entente.

In April 1916 Yasu officially placed Abyssinia in religious dependence on the Sultan of Turkey as Caliph and sent to the Turkish consul-general at Harrar an Abyssinian flag bearing the crescent and a confession of faith in Islam. About this time he informed his Moslem confederates—who had been told that Germany and Austria had embraced Islam and had imposed that faith upon France—that he would lead them against the Allies as soon as a great German victory should be announced.

[1] One result was raiding into the Sudan and adjacent territories by Abyssinians. These raids the central Government did not or could not prevent.

His anti-Christian, anti-Abyssinian attitude led to Yasu's downfall. The Allied representatives at Addis Abbaba, in particular the Hon. W. G. Thesiger, then the British minister, did much to counteract Turco-German propaganda and, except Ras Michael, all the Abyssinian chiefs were opposed to the Emperor's proceedings. They had the support of the people, the Shoans as well as the men of Tigré and Gondar, and they determined to end an intolerable situation. On Sept. 27 1916—the Feast of the Cross—by a public proclamation of the Abuna (the head of the church) Lij Yasu was declared dethroned, on the specific ground of his apostasy. His aunt, the Princess Zauditu (Judith), who had been a prisoner in the palace since Menelek's illness in 1910, was proclaimed empress. Dejaz (general) Taffari Makonnen, a cousin of Zauditu, was appointed heir to the throne and regent with the title of Ras (prince). The new régime was at once accepted, practically unopposed, by the chiefs and people of Shoa and by the imperial army (a force of 50,000 kept in the neighbourhood of the capital).

Lij Yasu was then at Harrar, a Moslem centre, arming the Somalis. On receipt of the news of his deposition he showed the weakness of his character by publicly renouncing Islam, a step which gained him no credit either with the Abyssinians or the Somalis. The garrison of Harrar (Abyssinians), sent by Yasu to oppose the Shoan troops which the new rulers had dispatched against him, joined his enemies. On Oct. 8 Yasu fled secretly from Harrar, making for the Danakil country. On the 9th Harrar was occupied by the Shoans, who killed some 400 unresisting Somalis before the slaughter was stopped through the intervention of the British consul.

Ras Michael was made of sterner stuff than his son; moreover, the Wollo Galla remained faithful to him and he was able to put some 80,000 men in the field. Wollo lies on the eastern edge of the Abyssinian plateau, with Gondar and Tigré N. and N.W. and Shoa to the S. Leaving 20,000 to 30,000 men to guard his northern frontier, Ras Michael marched S., hoping to capture Addis Abbaba by a rapid blow. Meantime the new Government had prepared to advance N., fixing on Shano, 40 m. N.E. of the capital, as the place of concentration. Michael, who was first in the field, had an engagement with the advanced force of the Shoans under Ras Lul Seged Oct. 17, before whom he gave way. But on the 10th Michael surrounded and destroyed Lul Seged's force in a furious battle in which over 12,000 men perished. Lul Seged himself was slain, but his resolute defence had delayed Michael's advance; it gave time to the Shoans to complete their concentration. By Oct. 21 they had 60,000 men at Shano, and a great superiority in artillery over Michael. On the 22nd Shoan cavalry under Ras Kassa[1] seized a position in the rear of Michael's army; the same day his force on the northern frontier was attacked and defeated by the Ras of Gondar (Waldo Giorgis). Cut off from his base, almost enveloped and with supplies running short, Michael's only alternative to being starved into surrender was to attack. The King chose the latter course and gave battle at Shano on Oct. 27. The fighting was desperate and the slaughter great. The Shoans were at first hard pressed but the timely arrival of Ras Kassa's cavalry decided the issue. The Wollo army was utterly routed, Michael was taken prisoner and all his artillery captured. This ended the campaign, in which in three weeks over 60,000 lives are said to have been lost, the casualties of the Shoans alone exceeding 20,000. The Fitaurai Hapti Giorgis, Minister of War, who had commanded in chief the Shoan forces, made no attempt to occupy Wollo or to pursue Lij Yasu and thus effectively pacify the country. He returned to Addis Abbaba where the Empress Zauditu reviewed the victorious troops, the ceremony ending with the parade of Ras Michael, a fine-looking, dignified man of about 65, chained to the chief who had captured him.

Profiting by the inactivity of the Government, Lij Yasu gathered together the remnants of his father's army. He managed to keep his footing in the Wollo country for the greater part of 1917 and finally took refuge in Magdala. Closely besieged, Magdala surrendered in Dec. 1917. Lij Yasu escaped, and thereafter appears to have led a wandering life among the Danakil and Somali. In Oct. 1918 he was appealing to the Turks in Arabia for help, and making attempts to raid the Jibuti railway. At the close of 1920 Yasu appeared in Tigré, apparently hoping to gain over that province, but in Jan. 1921 he was captured by Government forces.

The Government of the Empress Zauditu and Ras Taffari was pro-Ally and in the summer of 1919 missions were sent to London, Paris, Rome, Brussels and Washington to congratulate the Allies on their victory. These missions received good advice as to the necessity of an amelioration of social conditions in Abyssinia, the suppression of slavery—Menelek's conquests had given a great impetus to the slave trade—and the development of commerce and agriculture.

Economic Conditions and Trade.—Two great hindrances to the economic development of the country have been stated—internal disturbances and lack of adequate means of communication. After the close of the World War, and with the railway from the Gulf of Aden to Addis Abbaba completed, an improvement was anticipated. A British company, the Abyssinian Corporation, was formed in Dec. 1918, with the approval of the Foreign Office, but owing to restriction of shipping, the fluctuations of exchange and the fall in the price of coffee its first two years' operations were unsatisfactory. Nevertheless the total trade of Abyssinia increased. Valued at about £1,000,000 in 1905, it had more than doubled by 1910; and in 1920, in the absence of any official statistics, was roughly estimated at between £3,500,000 and £4,000,000. Hides and skins, coffee and beeswax are the chief exports. The chief imports are cotton goods and Maria Theresa dollars (minted at Trieste and an exact reproduction of the 1780 issue). The external trade of northern Abyssinia is with Massawa via Asmara; that of Shoa and Harrar with Jibuti and, to a small extent, with Zeila and Berbera (British Somaliland). These are all ancient routes to the sea-coast; to the old trade routes to the Sudan by the Blue Nile has been added that by the Baro-Sobat rivers. Gambela, on the Baro and 60 m. within the Abyssinian frontier, was leased to the Sudan Government in 1907, and in the Sobat flood season (June-Nov.) a steamer service is maintained with Khartum. Although the road from the Baro river to Gore, on the highlands, was and remained very bad, Gambela became an important transport centre. The value of its trade, £43,000 in 1910, was £103,000 in 1913 and was estimated at about £200,000 in 1919. Much of the trade in the country is in the hands of Greeks, Syrians and Arabs. The agricultural and mineral wealth of the country remain as yet—if the cultivation of coffee be excepted—scarcely tapped, and its water-power unutilized.

Abyssinia" (with map), *Geog. Jnl.*, Aug. 1911; Major F. L. Athill, "Through S. W. Abyssinia to the Nile," *ibid.*, Nov. 1920; C. H. Armbruster, *Initia Amharica, Part III. Amharic-English Vocabulary, Vol. I.* (1920). (F. R. C.)

ACHENBACH, ANDREAS (1815–1910), German painter (*see* 1.142), died in 1910.

ACHURCH, JANET [Mrs. C. Charrington] (1864–1916), English actress, was born in Manchester Jan. 17 1864. She married Charles Charrington June 1889. She first appeared at the Olympic theatre, London, Jan. 8 1883, with Geneviève Ward in the farce of *Betsy Baker*. Two years later she joined Frank Benson's company and played Shakespearean heroines; but her chief success was gained as Nora Helmer in Ibsen's *A Doll's House*, when that play was first produced in England in 1889. She appeared later in other Ibsen plays and in those of Bernard Shaw. She died at Ventnor Sept. 11 1916.

ADAM, JULIETTE (1836–), French writer (*see* 1.172), whose volumes of reminiscences of distinguished contemporaries numbered seven by 1910, subsequently published *Impressions françaises en Russie* (1912) and *Chrétienne* (1913), as well as various writings in pursuit of her lifelong policy of *revanche*, *L'heure vengeresse des crimes bismarckiens* (1915), *Guillaume II. 1890–9* (1917), and a volume of war sketches, *La vie des âmes* (1919).

ADAM, PAUL (1862–1920), French novelist (*see* 1.172), published in his later years various novels, including *Le Trust* (1910) and *Stéphanie* (1913). He was active in propaganda work during the World War, and shortly before his death published *Reims dévastée* and *Le Lion d'Arras*. He died in Paris Jan. 7 1920.

ADAMS, HENRY (1838–1918), American historian (*see* 1.175), died in Washington, D.C., May 27 1918. In 1910 his *Letter to*

[1] Abyssinian envoy to London for the coronation of George V.

American Teachers of History appeared, and in 1911 his *Life of George Cabot Lodge*. In 1913 his *Mont Saint Michel and Chartres* (privately printed in 1904) was published by authority of the American Institute of Architects, a scholarly interpretation of the architecture and literature of the mediaeval Church. In 1918 his autobiographical *The Education of Henry Adams* (privately printed in 1906) was issued for the public. No book of its decade evoked more discussion in America. In 1919 *The Degradation of the Democratic Dogma* (consisting of several essays previously published together with one hitherto unpublished) was issued, with an introduction by his brother, Brooks Adams.

His brother, CHARLES FRANCIS ADAMS (*see* 1.175), died in Washington, D.C., March 20 1915. In 1911 he published *Studies Military and Diplomatic, 1775–1865*, and in 1913 *Trans-Atlantic Historical Solidarity* (lectures delivered at Oxford).

In 1916 Worthington C. Ford edited *Charles Francis Adams, an Autobiography*, from papers deposited in 1913 with the Massachusetts Historical Society. See also the same editor's *A Cycle of Adams Letters, 1861–1865* (1920).

ADAMS, MAUDE (1872–), American actress, was born in Salt Lake City, Utah, Nov. 11 1872. Her family name was Kiskadden, but she adopted the maiden name, Adams, of her mother, an actress. She early played child's parts, and at the age of 16 went to New York. From her appearance in Hoyt's *A Midnight Bell*, in 1889, her popularity grew steadily. In 1897 she was first starred by Charles Frohman as Lady Babbie in *The Little Minister;* and in many of Barrie's other plays she won applause. She introduced Rostand to the American stage, taking the title-rôle in *L'Aiglon* (1901), and in *Chantecler* (1911). Other plays in her repertory were *Romeo and Juliet* (1900); *The Pretty Sister of José* (1903); *The Jesters* (1908) and *As You Like It* (1910).

ADAMSON, WILLIAM (1863–), British Labour politician, was born at Halbeath, Fife, April 2 1863. When very young he began to work in the pits, and for many years led the life of a miner. In 1902 he became assistant secretary of the Fife and Kinross Miners' Association, and in 1908 its general secretary. He stood for Parliament unsuccessfully in Jan. 1910, but in Dec. was elected for West Fife. On the reorganization of the Labour party in 1917, Mr. Adamson succeeded Mr. Arthur Henderson as its chairman, and in 1918 he was sworn of the Privy Council. In 1919 the Labour party, as the second strongest combination in the House of Commons, decided to assume the position of the official Opposition, and Mr. Adamson became its leader, taking his seat on the front Opposition bench. As an Opposition leader he also congratulated the Speaker upon his reëlection. He took part in the debate on the King's speech, pointing out the views of the Labour party on the industrial situation. Mr. Adamson took a prominent part in the various trade-union discussions in 1919, 1920 and 1921, particularly in the numerous debates on the coal industry in these years.

ADDAMS, JANE (1860–), American sociologist (*see* 1.183), published *Twenty Years at Hull House* (1910), with much autobiographical comment; *A New Conscience and an Ancient Evil* (1911) and *The Long Road of Women's Memory* (1916). She did much to promote the cause of woman suffrage, and in 1912 was an active worker in behalf of the short-lived National Progressive party. After the outbreak of the World War in Europe she attended the International Congress of Women held at The Hague in 1915, and was elected president. She was also appointed chairman of the International Committee of Women for Permanent Peace. She was an avowed pacifist after America had entered the World War.

ADDISON, CHRISTOPHER (1869–), English politician and medical practitioner, born June 19 1869 at Hogsthorpe, Lincs., was educated at Trinity College, Harrogate, and received his medical training at St. Bartholomew's hospital. He graduated at London University, taking the M.B. (Honours in For. Med.) and the B.S. in 1892, and the M.D. in 1893. He was elected F.R.C.S. in 1895. He became lecturer in Anatomy both at his own hospital and at Charing Cross hospital; professor of Anatomy at University College, Sheffield; and Hunterian professor at the Royal College of Surgeons in 1901. Besides the private practice of his profession, he contributed largely to medical knowledge by the publication of several books, mainly on the anatomy of the pancreas and the abdominal viscera, by papers in the *Proceedings* of the Royal Society and in professional journals, and by editing for a time the *Quarterly Medical Journal*. He took, moreover, a leading part in medical education in London University. In 1910 he entered Parliament as Liberal member for Hoxton. He immediately became active in the House. In conjunction with Sir George Newman he was mainly instrumental in securing the medical treatment of school children and State provision for medical research; and he was one of the few doctors of distinction who supported Mr. Lloyd George in his struggle with the profession over the Insurance Act (1912). The valuable support he then gave to Mr. Lloyd George in reconciling the doctors to his proposals created a firm bond between him and the future Prime Minister. When in 1914 Mr. Charles Trevelyan, on the outbreak of war, resigned the Parliamentary Secretaryship of the Board of Education, Dr. Addison was appointed in his place. But his principal work during the war was effected at the Ministry of Munitions, where Mr. Lloyd George obtained his assistance as Parliamentary Secretary when the office was created under the first Coalition Ministry in 1915. So long as Mr. Lloyd George was Minister, Dr. Addison was his right-hand man in the strenuous labours of the office, resulting in the enormous multiplication of engines of war, and in the redeeming of many vital industries, fertilizers, tungsten and potash from German control; and when Mr. Lloyd George formed a Government himself in December 1916, he placed him at the head of the department. Dr. Addison had to deal with various labour troubles, and in particular with a serious strike of engineers in May 1917. In July he left the Ministry of Munitions to become Minister of Reconstruction without portfolio. In this new but very important work his policy was apparently influenced by a rather idealistic vision of a "new world" after the war. One result was the unemployment dole, at first a necessity, but afterwards a hindrance to a return to normal life. To promote national health had always been his main object in politics, and when Mr. Lloyd George reconstructed his Ministry in the beginning of 1919, he entrusted the Local Government Board to Dr. Addison, that he might complete Lord Rhondda's work and transform it into a Ministry of Health. This was accomplished in June. He also carried through Parliament an important Housing and Town-Planning bill compelling local authorities to provide housing schemes, and obtained parliamentary sanction to an arrangement for the issue by such authorities of housing bonds. The ambitious medical establishment created by him was subjected to a good deal of criticism on the score of economy during 1920; and on the reconstruction of the Ministry in March 1921 he was transferred from the new department to become once more a minister without portfolio. This position he resigned on July 14. He married in 1902 Isobel Gray, and had two sons and two daughters.

ADEN (*see* 1.190).—The territory comprises the peninsulas of Aden proper and Little Aden, a strip of mainland including the villages of Sheikh 'Othman, 6 m. inland, 'Imad and Hiswa, and Perim Island. The town of Aden and its port Tawahi, 4 m. westward, are connected by a good carriage-road with the Somali settlement of Ma'la about midway. The harbour—known as Bandar Tawiya or Aden-West Bay—lies between the main and Little Aden peninsulas (Jebel Ihsan or Hasan); it extends 8 m. from E. to W. and 3 m. from N. to S. and is divided into a western and an inner bay by a spit of land. The depth of water at the main entrance is 4½ to 5 fathoms and in the western bay 3 to 4 fathoms. For lack of docks and quayage, large vessels lie off Steamer Point and all cargo is handled by means of lighters, the labour being either Somali or Arab. Sailing and small craft load and unload at Ma'la. The population of Aden proper in 1915 was 36,900 and of the whole settlement 46,000, of whom about 23,000 were Arabs and a large part of the remainder Somalis. European residents and Christians numbered 2,000 to 3,000, Mohammedans about 34,000 and Jews 3,700.

On March 1 1921 the administration of Aden was transferred from the India Office to the Colonial Office, which also exercises political influence, in varying degrees, over the confederations of tribes inhabiting the interior as far as the Yemen frontier and over certain tribes of the Hadhramaut. The revenue in 1914–5 amounted to 87½ lakhs of rupees (approx. £580,000), derived mainly from the Aden Port Trust Fund (£34,000), Aden Settlement Fund (£28,000), Local Supply Bills (£257,000), Imperial and municipal receipts (£215,700), Post Office (£34,000), excise, customs and income tax. The expenditure in the same year was £556,000.

The value of the total trade (including specie) amounted to £8,526,000 (1913–4), and had increased to £10,045,000 in 1918–9 and £13,641,000 in 1919–20. Of the last amount, £7,124,000 represented exports and £6,517,000 imports. A very large proportion represents simple transhipment; but Aden is also the centre of the exporting and importing business of the Red Sea commercial region made up of the Hejaz, Asir, Yemen, Hadhramaut, Eritrea, Abyssinia and British and French Somaliland. The principal articles of import in 1919–20 were: cotton piece-goods and yarn £2,180,000, hides and skins £1,291,000, coal £626,000, grain and flour £541,000, coffee, sugar, tobacco, hardware, petroleum and provisions. The exports were: hides and skins £2,123,000, cotton goods £2,112,000, coffee £456,000, grain and pulse £329,000, tobacco £213,000 and salt £151,000. Local products, including *kat*, firewood, live animals, *ghi*, dates, honey, wax, gums and sesame oil, to the value of about £125,000, were exported in 1919–20. 1,065 steam vessels of aggregate tonnage 2,736,391 and sailing craft of tonnage 365,569 cleared in the year ending March 1919. The port is free except for a small duty on alcoholic liquors and intoxicating drugs. Licenses are required for the importation of petroleum and small arms and ammunition.

The water supply, formerly very uncertain and unsatisfactory, is mainly from reservoirs and from condensation. The reservoirs have a storage capacity of 8,000,000 gal. but the most effective supply is obtained by condensation of sea water. Six condensers yield 52,000 gal. daily.

Aden produces no foodstuffs. The only local industries are the preparation of salt (Italian and Indian concessions, with an output of 124,000 tons in 1916–7), the unhusking of Arabian coffee berries and the making of cigarettes from tobacco imported from Egypt. The main trade routes are:—to San'a, via Lahej, 227 m.; to Mocha and Hodeida, via Ta'izz, 299 m.; and to Makalla, via Nisab, 413 m.

During the World War, Turkey brought pressure to bear on certain of the tribes of the Aden Protectorate (*see* ARABIA) and in July 1915 a Turkish army several thousand strong advanced on Lahej, the 'Abdali capital (21 m. N.). A small British force sent to assist in its defence proved altogether inadequate and had to retreat to Aden. The Turks occupied Sheikh 'Othman, but were unable to threaten Aden itself. The loyal Sultan was killed. On July 20 of the same year reinforced Aden troops surprised the Turks at Sheikh 'Othman, inflicted on them considerable loss and they retired to Lahej. In Oct. and in Dec. cavalry had small affairs with enemy reconnoitring parties in which the latter were driven off. In Jan. 1916, owing to the Turks again despatching troops to coerce the tribes in the east of the Protectorate, a demonstration in support of the latter was made by the Aden column. It located the enemy force near the village of Subar (4 m. S.S.E. of Lahej), inflicted considerable loss on it, and the Turkish pressure was relieved. In Dec. 1917 the defensive line at Aden described an arc of about 11 m. radius and there had been constant patrol skirmishes and small actions which continued until the Armistice.

ADLER, VIKTOR (1852–1918), Austrian politician, was born at Prague June 24 1852, the son of a well-to-do business man, who moved with his family to Vienna when the son was three years old. Here he studied at the Schotten-gymnasium, where he gathered round him a circle of fellow-students who thus early began to occupy themselves with political and social questions, their interest having been aroused by the works of Lassalle and by the events of 1866 and 1870. It was at this time, too, that the Social Democratic Labour movement first began to affect Austria. On the basis of the new law respecting combinations, passed during the era of Liberal-bourgeois reform, arose the first proletarian organizations, and the battles between the adherents of state assistance (Lassalle) and of self-help (Schultz-Delitzsch) were being publicly fought out. At the university Adler entered the German national students' association, "Arminia," became a member of the committee of the German Reading Union, and belonged to the national and democratic group of intellectuals who, since the middle of the 'seventies, had grouped themselves around the deputy Schönerer, and had formulated the so-called Linz programme (*see* also PERNERSTORFER). He studied medicine, attaching himself especially to the psychiatrist Meynert, and in addition to his medical practice occupied himself with industrial hygiene. In his later career he continued to take special interest in public health questions. Intending to adopt factory inspection as a career, he went in 1883 to study in Switzerland and in London, where he came into close touch with Engels. On his return to Vienna, however, he turned entirely to politics. The Workmen's party, weakened by the general economic depression, by internal dissensions and by police prosecutions, had sunk into political insignificance. In the 'eighties the "Radicals" (Most, Peukert) and the "Moderates" were at daggers drawn. The Government of Count Taaffe, on the other hand, supporting itself on the lower middle classes, which held the balance of votes in Austria and especially in Vienna, introduced legislation for the organization of industry on the guild system. It attempted, indeed, to conciliate the working classes by social-political legislation on the German model, but at the same time used the excuse given by the methods of violence advocated by the Radicals to suspend the ordinary law in Vienna and certain other districts, as a preliminary to anti-Socialist and anti-Anarchist legislation. The ground being thus prepared by the Government, Adler undertook to restore unity in the ranks of Labour. In 1886 appeared his paper *Gleichheit* (Equality), eventually succeeded by the *Arbeiterzeitung*, the principal organ of the Social Democratic party, which Adler continued to conduct till his death. His object was to organize the workmen as a political party, and the best methods seemed to him to be those of public propaganda and open political warfare. The united Labour party (*Arbeiterpartei*) was to keep the socialistic ideal constantly in view, but was not to despise small gains. By his sound judgment, and his exceedingly clever handling of men, he succeeded, in spite of difficulties within and without the party, in reaching the first stage in the path he had marked out by carrying the whole party with him, in the last days of the year 1888, on the basis of a carefully weighed programme at the party meeting held at Hainfeld, Lower Austria. He was able to appear in July 1889 at the first congress of the Second International (of which he was from that time an official) as the representative of the united Austrian party; and the first May Day celebration (1890), the first of those imposing demonstrations by which he sought to give a striking proof of the will and the power of the working classes, showed that a new epoch had dawned for Austrian Social Democracy. Adler, who was repeatedly involved in legal proceedings and condemned to terms of several months' imprisonment for political offences, was from that time the acknowledged leader of the party.

In consequence of the ever-increasing extension of its industrial and political organization, in which Adler took an energetic part, the party obtained an increasing influence in public life, which was further increased by the division of the bourgeois parties on the nationality question. Adler understood how to make the best of these conditions. He regarded it as his first task to secure for the workmen representation in Parliament. After the three years' struggle for electoral reform (1893–6), which followed the proposals for the modification of the franchise put forward by the prime minister, Count Taaffe, some measure of electoral reform was secured. But it was insufficient, and it was only when the Government had decided that an extension of the franchise was the sole means by which the monarchy could be protected against the centrifugal forces of nationality, that Adler was able to use the impression made by the confusions in Hungary and the Russian revolution of 1905 to interpose with all his weight and help to secure the triumph of universal and equal suffrage (1907).

The Social Democratic party increased their representation from 11 deputies to 87. Adler himself entered the Diet of Lower Austria in 1902, and in 1905 was elected to the Reichsrat, where until his death he played an important part as chairman of the committee of the Social Democratic party and of the Social Democratic Deputies' Club, taking part in all important debates.

New dangers, due to the nature of the Austrian State with its rival nationalities, more than once threatened the unity of the

party. Adler had always been a Pan-German, but regarded the disruption of Austria and the union of German Austria with Germany as a distant goal which had no place in the practical politics of the moment. He aimed therefore at establishing a friendly relation between the nations on the basis of democracy. When the Austrian Germans were threatened hy the language ordinance of Count Badeni, and Parliament itself by a *coup d'état*, Adler made an alliance with the German parties, rallied the working classes, and overthrew the Polish prime minister (1897). At the party congresses, Adler tried to accommodate the conflicting national standpoints on the basis of the principles laid down in the Brünn programme (equal rights and national autonomy). But the unified organization of the trade unions and the union of the Social Democratic parties were destroyed in consequence of these differences, more especially by the intransigeance of the Czechs. No general party congress of the different Austrian nationalities has taken place since 1905.

In the congresses and in the secretariat of the International Adler, with Jaurès and Bebel, played the most prominent part, whether as leader, adviser, or mediator. He took part in the great peace demonstration of the International at Basel, and in the meeting of the secretariat in Brussels immediately before the outbreak of the World War. In spite of bad health, which for many years in succession had compelled him to spend much time on the Riviera and at Nauheim, he travelled in the spring of 1917, immediately after the trial of his son Friedrich, to Stockholm to the proposed Socialist congress. After the collapse of Austria in 1918, at the constituent session of the provisional German-Austrian National Assembly, which was formed by the meeting of all the German deputies, he read the declaration of the Social Democrats, in which they expressed their willingness, in association with the other German-Austrian parties, to build the new State on the basis of democracy and the self-determination of their own and other nationalities, without prejudice to a possible association with the German Empire.

In his opening words Adler said: "You will permit an old man to say that at last we see the accomplishment of what we have longed for since our youth." He did not long survive that day. He held for a few days the office of Foreign Minister, entrusted to him by the new State Council (*Staatsrat*), but in spite of his iron determination he was not able to bear the strain. He broke down on Nov. 11 and died on the 12th, 1918, the day on which the State Council had decided to proclaim German Austria a democratic republic and an integral part of the German *Reich*.

His works include articles scattered in various newspapers, in the *Neue Zeit*, *Kampf*, *Deutsche Worte*, in addition to those in the *Arbeiterzeitung*; pamphlets, among which are *Die Fabrikinspektion, insbesondere in England und der Schweiz* (1884); *Die Arbeiterkammer und die Arbeiter* (1886); *Das allgemeine, gleiche und direkte Wahlrecht und das Wahlunrecht in Oesterreich; Alcoholismus und Gewerkschaft* (many editions). See also *Die Gleichheit vor dem Ausnahmegericht* (1889); *Schwurgerichtsprozess gegen Doktor Viktor Adler wegen Verbrechens der Störung der öffentlichen Ruhe* (1894).

His son, Friedrich Adler (1879–), Austrian politician, was born at Vienna July 9 1879. He was educated at the Realgymnasium in Vienna, and studied philosophy at the university of Zurich. He was privatdozent (lecturer by diploma) in physics at the university of Zurich from 1907 to 1911, editor of the Social Democratic daily *Volksrecht* from 1910 to 1911, and from 1911 to 1916 secretary of the Austrian Social Democratic party and editor of the monthly *Kampf*. During the World War he was in sympathy with the conclusions reached at the conferences of the Socialists of the Left at Zimmerwald and Kienthal. In despair over the break-up of the International, he shot (Oct. 21 1916) the Austrian prime minister, Count Stürgkh, in the expectation that the deed would be a signal for the rising of the proletariat against the war. After a speech in his own defence which aroused much attention he was, on May 19 1917, condemned by a special tribunal to death, a sentence commuted to 18 years' imprisonment. During the chaos of the autumn of 1918 he was amnestied (Nov. 1). In 1919 he was elected to the National Assembly, and became vice-president of the committee of the Social Democratic party and of the Union of the Social Democratic deputies. As president of the Austrian National Workmen's Council and of the Vienna District Workmen's Council he exercised great influence in the party. On his initiative was founded the International Labour Association of Socialist Parties, of which the first meeting was held in Vienna in Feb. 1921. He made the opening statement, and became secretary of the Association.

His works are: *Die Erneuerung der Internationale* (1918); *Ernst Mach's Ueberwindung des mechanischen Materialismus* (1918); *Ortszeit, Systemszeit, Zonenzeit und das ausgezeichnete Bezugssystem der Electrodynamik, eine Untersuchung über die Lorentzische und die Einstein'sche Kinematik* (1920). See also *Friedrich Adler vor dem Ausnahmegericht* (1919).

ADMIRALTY ADMINISTRATION (*see* 1.195).—The history of the British Admiralty during the World War of 1914–8 is the history of the evolution of the naval staff and of a great expansion of the technical and administrative departments. All departments expanded during the war, but the evolution of the naval staff was more than mere expansion, for it represented the adoption of definite principles of staff work which were intended to prevent those responsible for the conduct of naval operations being crushed under a load of administrative business.

This was, indeed, no new trouble. It had been experienced ashore and afloat in peace and war. Kempenfelt and Tryon had commented strongly on it. "We are every day," wrote the former to Middleton in 1770, "plagued and puzzled with minutiae from morning to night whilst essentials are neglected." "It cannot be right," wrote Tryon in 1890, "that the Commander-in-Chief should find himself devoting his time to coaling and watering, provisioning, storing and repairing." They were seeking after a solution of the difficulty which lay in a clear distinction between fighting and supply, between the use of the weapon, and its supply and maintenance in an efficient state. This principle had been introduced into the British army by Lord Haldane, and is equally applicable to naval work. It is a principle vital to war, for on the outbreak of war the whole rhythm of work changes. Work expands tenfold in extent and an hundredfold in urgency, and without some clear distinction of this sort it is impossible to give to the conduct of operations the attention it deserves.

The principle was not to be found in the British Admiralty at the beginning of the war. The First Sea Lord was just as interested in the design of ships as in operations, and the War Staff lacked some of the most important elements of staff work. The important distinction between fighting and supply was not to be found; the Chief of the War Staff had no seat on the Board, and the methods of conducting the work of a large staff had not been studied. Up to 1909 the Intelligence Department had to some extent filled the place of a staff. It had gradually grown from the Foreign Intelligence Branch or Committee instituted in 1883, and had developed into the Naval Intelligence Department, consisting of four divisions—foreign, trade, mobilization and war—of which the two latter were evidently tentative efforts towards an Operations Division. In Sept. 1909 it split into two separate departments, intelligence and mobilization, of which the latter was clearly the beginning of an Operations Division, but was killed by its name, for it soon became immersed in the task of manning and mobilization, which belongs wholly to the sphere of supply. The Intelligence Department sank more and more into the position of a mere handmaid for the collection of data and translations from the foreign press. Its development was hampered by the intense suspicion with which most flag officers regarded anything that seemed to trespass on their prerogative of command. The idea of a staff was held in great disfavour. The word was anathema at the Admiralty and not allowed to be used in War College publications, and it is no secret that the most distinguished flag officers were opposed to the institution of a staff in 1912.

The naval staff really dates from the Memorandum of Jan. 1912 issued by Mr. Churchill, after the breakdown of the old system at the Agadir crisis, but it had not had sufficient time to develop before the World War broke on it and broke it up. It consisted of three small divisions—operations, intelligence

On March 1 1921 the administration of Aden was transferred from the India Office to the Colonial Office, which also exercises political influence, in varying degrees, over the confederations of tribes inhabiting the interior as far as the Yemen frontier and over certain tribes of the Hadhramaut. The revenue in 1914–5 amounted to 87½ lakhs of rupees (approx. £580,000), derived mainly from the Aden Port Trust Fund (£34,000), Aden Settlement Fund (£28,000), Local Supply Bills (£257,000), Imperial and municipal receipts (£215,700), Post Office (£34,000), excise, customs and income tax. The expenditure in the same year was £556,000.

The value of the total trade (including specie) amounted to £8,526,000 (1913–4), and had increased to £10,045,000 in 1918–9 and £13,641,000 in 1919–20. Of the last amount, £7,124,000 represented exports and £6,517,000 imports. A very large proportion represents simple transhipment; but Aden is also the centre of the exporting and importing business of the Red Sea commercial region made up of the Hejaz, Asir, Yemen, Hadhramaut, Eritrea, Abyssinia and British and French Somaliland. The principal articles of import in 1919–20 were: cotton piece-goods and yarn £2,180,000, hides and skins £1,291,000, coal £626,000, grain and flour £541,000, coffee, sugar, tobacco, hardware, petroleum and provisions. The exports were: hides and skins £2,123,000, cotton goods £2,112,000, coffee £456,000, grain and pulse £329,000, tobacco £213,000 and salt £151,000. Local products, including *kat*, firewood, live animals, *ghi*, dates, honey, wax, gums and sesame oil, to the value of about £125,000, were exported in 1919–20. 1,065 steam vessels of aggregate tonnage 2,736,391 and sailing craft of tonnage 365,569 cleared in the year ending March 1919. The port is free except for a small duty on alcoholic liquors and intoxicating drugs. Licenses are required for the importation of petroleum and small arms and ammunition.

The water supply, formerly very uncertain and unsatisfactory, is mainly from reservoirs and from condensation. The reservoirs have a storage capacity of 8,000,000 gal. but the most effective supply is obtained by condensation of sea water. Six condensers yield 52,000 gal. daily.

Aden produces no foodstuffs. The only local industries are the preparation of salt (Italian and Indian concessions, with an output of 124,000 tons in 1916–7), the unhusking of Arabian coffee berries and the making of cigarettes from tobacco imported from Egypt. The main trade routes are:—to San'a, via Lahej, 227 m.; to Mocha and Hodeida, via Ta'izz, 299 m.; and to Makalla, via Nisab, 413 m.

During the World War, Turkey brought pressure to bear on certain of the tribes of the Aden Protectorate (*see* ARABIA) and in July 1915 a Turkish army several thousand strong advanced on Lahej, the 'Abdali capital (21 m. N.). A small British force sent to assist in its defence proved altogether inadequate and had to retreat to Aden. The Turks occupied Sheikh 'Othman, but were unable to threaten Aden itself. The loyal Sultan was killed. On July 20 of the same year reinforced Aden troops surprised the Turks at Sheikh 'Othman, inflicted on them considerable loss and they retired to Lahej. In Oct. and in Dec. cavalry had small affairs with enemy reconnoitring parties in which the latter were driven off. In Jan. 1916, owing to the Turks again despatching troops to coerce the tribes in the east of the Protectorate, a demonstration in support of the latter was made by the Aden column. It located the enemy force near the village of Subar (4 m. S.S.E. of Lahej), inflicted considerable loss on it, and the Turkish pressure was relieved. In Dec. 1917 the defensive line at Aden described an arc of about 11 m. radius and there had been constant patrol skirmishes and small actions which continued until the Armistice.

ADLER, VIKTOR (1852–1918), Austrian politician, was born at Prague June 24 1852, the son of a well-to-do business man, who moved with his family to Vienna when the son was three years old. Here he studied at the Schotten-gymnasium, where he gathered round him a circle of fellow-students who thus early began to occupy themselves with political and social questions, their interest having been aroused by the works of Lassalle and by the events of 1866 and 1870. It was at this time, too, that the Social Democratic Labour movement first began to affect Austria. On the basis of the new law respecting combinations, passed during the era of Liberal-bourgeois reform, arose the first proletarian organizations, and the battles between the adherents of state assistance (Lassalle) and of self-help (Schultz-Delitzsch) were being publicly fought out. At the university Adler entered the German national students' association, "Arminia," became a member of the committee of the German Reading Union, and belonged to the national and democratic group of intellectuals who, since the middle of the 'seventies, had grouped themselves around the deputy Schönerer, and had formulated the so-called Linz programme (*see* also PERNERSTORFER). He studied medicine, attaching himself especially to the psychiatrist Meynert, and in addition to his medical practice occupied himself with industrial hygiene. In his later career he continued to take special interest in public health questions. Intending to adopt factory inspection as a career, he went in 1883 to study in Switzerland and in London, where he came into close touch with Engels. On his return to Vienna, however, he turned entirely to politics. The Workmen's party, weakened by the general economic depression, by internal dissensions and by police prosecutions, had sunk into political insignificance. In the 'eighties the "Radicals" (Most, Peukert) and the "Moderates" were at daggers drawn. The Government of Count Taaffe, on the other hand, supporting itself on the lower middle classes, which held the balance of votes in Austria and especially in Vienna, introduced legislation for the organization of industry on the guild system. It attempted, indeed, to conciliate the working classes by social-political legislation on the German model, but at the same time used the excuse given by the methods of violence advocated by the Radicals to suspend the ordinary law in Vienna and certain other districts, as a preliminary to anti-Socialist and anti-Anarchist legislation. The ground being thus prepared by the Government, Adler undertook to restore unity in the ranks of Labour. In 1886 appeared his paper *Gleichheit* (Equality), eventually succeeded by the *Arbeiterzeitung*, the principal organ of the Social Democratic party, which Adler continued to conduct till his death. His object was to organize the workmen as a political party, and the best methods seemed to him to be those of public propaganda and open political warfare. The united Labour party (*Arbeiterpartei*) was to keep the socialistic ideal constantly in view, but was not to despise small gains. By his sound judgment, and his exceedingly clever handling of men, he succeeded, in spite of difficulties within and without the party, in reaching the first stage in the path he had marked out by carrying the whole party with him, in the last days of the year 1888, on the basis of a carefully weighed programme at the party meeting held at Hainfeld, Lower Austria. He was able to appear in July 1889 at the first congress of the Second International (of which he was from that time an official) as the representative of the united Austrian party; and the first May Day celebration (1890), the first of those imposing demonstrations by which he sought to give a striking proof of the will and the power of the working classes, showed that a new epoch had dawned for Austrian Social Democracy. Adler, who was repeatedly involved in legal proceedings and condemned to terms of several months' imprisonment for political offences, was from that time the acknowledged leader of the party.

In consequence of the ever-increasing extension of its industrial and political organization, in which Adler took an energetic part, the party obtained an increasing influence in public life, which was further increased by the division of the bourgeois parties on the nationality question. Adler understood how to make the best of these conditions. He regarded it as his first task to secure for the workmen representation in Parliament. After the three years' struggle for electoral reform (1893–6), which followed the proposals for the modification of the franchise put forward by the prime minister, Count Taaffe, some measure of electoral reform was secured. But it was insufficient, and it was only when the Government had decided that an extension of the franchise was the sole means by which the monarchy could be protected against the centrifugal forces of nationality, that Adler was able to use the impression made by the confusions in Hungary and the Russian revolution of 1905 to interpose with all his weight and help to secure the triumph of universal and equal suffrage (1907).

The Social Democratic party increased their representation from 11 deputies to 87. Adler himself entered the Diet of Lower Austria in 1902, and in 1905 was elected to the Reichsrat, where until his death he played an important part as chairman of the committee of the Social Democratic party and of the Social Democratic Deputies' Club, taking part in all important debates.

New dangers, due to the nature of the Austrian State with its rival nationalities, more than once threatened the unity of the

feet when the World War broke out. It laboured under a further handicap: practically all senior officers were opposed to it. They were wedded to centralization. Centralization had become engrained in their bones from boyhood, and their whole outlook was necessarily opposed to a staff. The deficiencies of the system could be seen in the conduct of the Dardanelles campaign. It is clear that there was no machinery for the intensive investigation of a big strategical question. The First Lord was impressed with an exaggerated estimate of the Queen Elizabeth's guns, and the War Staff could neither supply a sufficiently trenchant criticism of the project nor could they grip the problem and transform it into a workable proposition by segregating a force and training it as the Zeebrugge force was afterwards trained.

Enough has been said to show that the war staff lacked the staff spirit, and a knowledge of the principles of staff organization and of the conduct of staff work. One bright spot, however, shone in it. While the operations side became more and more narrowly centralized, the intelligence side, under Sir William Hall, summoned a vast reserve of civilian talent to its aid. Very early in the war a system of special intelligence based on wireless directionals had begun to develop, and though cramped and restricted by the obsession of secrecy had proved of great value. In Dec. 1916, when Adml. Sir John Jellicoe came to the Admiralty, he instituted an anti-submarine division, which was no more than a belated plans division directed to a special purpose, but it was not till 1917 that the staff was thoroughly reorganized and really began to function as a staff. In Dec. 1916 it was organized as follows:—

Chief of War Staff

Operations Division | Intelligence | Signal Section Apr. 1916 | Mobilization

Trade Division Aug. 23 1914 | Anti-submarine Division Dec. 1916

Sir Eric Geddes gave an immense impetus to the system, which was forced upon the Government by the exigencies of war, and in its main outlines was merely the system of Moltke, Lord Haldane, and every modern army, adapted to naval needs. These can be briefly summarized as follows. The work of a staff follows three lines of practical cleavage: (*a*) operations (or direction), (*b*) administration, and (*c*) technical. Operations (or direction) enshrines the main purpose of a business; administration is responsible for its maintenance and equipment in an efficient state; technical control deals with the scientific aspect of applied sciences associated with the business. Finance and the Secretariat interpenetrate the whole. Operations (or direction) is the premier function, and splits into two main divisions, operations (minor) and intelligence. It is the special task of operations to appreciate the situation continuously, to assist the Command in the consideration of requirements and with the preparation and conduct of operations, and to convert the intentions, policy and decisions of the Command into orders and instructions. It is its business to visualize the situation continuously on an operations chart and to furnish all branches and technical services with timely information of all requirements. The function of intelligence is to collect, sift and distribute information of the enemy, and by the cumulative intelligence arising out of its work to help operations to appreciate the situation. Administration and technical comprise all the great services of supply and technical work, including personnel, pay, victualling, stores, transport, and the crafts of hydrography and surveying, navigation, marine engineering, naval construction, gunnery, torpedoes, mine-laying, mine-sweeping and signals. Each service is responsible for its internal efficiency, and the Chief of the Staff is responsible for the coördination of all, while to assist him in this a training and staff division is required which acts as the trustee of staff principle and organization and is also responsible for staff training, principles of training, staff history and manuals of war. No one of the three great branches is more important than another. Like the brain, heart and lungs, all are complementary to each other. If there are no ships there can be no operations; if the operations are badly conducted, the best ships will be useless; a new technical invention may revolutionize operations, and the whole service must rest on a basis of good discipline and sound financial administration.

The first step towards these principles was really taken in May 1917, when the term "War Staff" was altered to "Naval Staff" and the office of Chief of the Naval Staff was merged in the First Sea Lord (Admiral Jellicoe), while a Deputy Chief of the Naval Staff (Vice-Admiral Oliver) and an Assistant Chief (Rear-Admiral Duff) were appointed with seats on the Board. This gave the naval staff direct representation on the Board, and the presence of three members ensured the necessary authority to carry through any operation of war. The D.C.N.S. directed all operations and movements of the fleet, while the A.C.N.S. was responsible for mercantile movements and anti-submarine operations.

The office of Controller was revived, and Sir Eric Geddes appointed to fill it, with the rank of Honorary Vice-Admiral, all questions of supply being thus practically merged in his hands; but he had barely filled the office two months when he took Sir Edward Carson's place as First Lord July 20 1917. On Sept. 6 1917 a Deputy First Sea Lord, Sir Rosslyn Wemyss, was added to the Board to control operations abroad and questions of foreign policy. Sir Oswyn Murray too had succeeded Sir Graham Greene as Permanent Secretary in Aug. 1917.

In Oct. 1917 the development of the staff was carried one step further by the formation on Oct. 19 of two Committees of the Board—the Operations Committee and the Maintenance Committee. The First Lord was chairman of both, and the former consisted of the First Sea Lord and C.N.S., the Deputy 1st S.L., D.C.N.S., A.C.N.S., and 5th Sea Lord. The latter consisted of the Deputy 1st S.L. (representing the operations committee), 2nd S.L. (personnel), 3rd S.L. (material), 4th S.L. (transport and stores), Civil Lord, Controller and Financial Secretary.

The direction of operations was finally handed over to the C.N.S. by an order in Council of Oct. 1917, under which he became responsible for the issue of orders affecting war operations to the fleet. It empowered such orders to be issued in his own name as C.N.S., and not as previously by the secretary in the name of the Board.

These measures were accompanied by the institution of further divisions of the staff, including a plans division, and by Oct. 1917 the Board and naval staff had assumed the following form:—

Board of Admiralty

1st L.

1st S.L. | D.C.N.S. | A.C.N.S. | 5th S.L. | Deputy 1st S.L. || (Deputy 1st S.L.) | 2nd S.L. | 3rd S.L. | 4th S.L. | Civil L. | Controller

Parl. and Finance Secretary

Operations Committee | Maintenance Committee

Permanent Secretary

Naval Staff
C.N.S. and 1st S.L. (Adml. Jellicoe)

- D.C.N.S. (Acting V.A. Oliver)
  - Operations (R.A. Hope)
  - Signals Aug. 18 1917 (Comm. R. L. Nicholson)
  - Plans Oct. 8 1917 (R.A. Roger Keyes)
- Intelligence (R.A. Wm. Hall)
- Trade (Capt. Alan G. Hothan)
- A.C.N.S. (R.A. Duff)
  - Anti-Submarine Dec. 16 1916 (Capt. W. W. Fisher)
  - Mine-Sweeping May 23 1917 (Capt. Lionel Preston)
  - Mercantile Movements Oct. 1 1917 (Capt. Fred Whitehead)

One of the most important divisions of the naval staff was the mercantile movements division, which had been started as a convoy section, under the management of Paymaster Capt. H. W. Manisty. It was here in May 1917 that an operations chart came into use for the direction of convoys, on which the movements of submarines derived from wireless directionals and other reports were plotted, day and night. Operations divisions, troubled like Martha over many things, had never been able to deal in big plans, and this work was undertaken by the plans division which drew up plans for the mining of the Bight, the Great Northern Barrage (in conjunction with the U.S. navy), the Dover Barrage, the Otranto Barrage and numerous smaller operations.

The ease with which the distinction between operations and administration can be applied is illustrated in the submarine and auxiliary patrol services. In both these services the administrative work (such as regulations, conditions of entry, stores, personnel) was dealt with by a centre which had very little or nothing whatever to do with operations (Commodore (S) in the one case and the Auxiliary Patrol Office in the other), and the system worked very successfully from first to last. The reorganization of staff work was not limited to the Admiralty. It extended to every command, and in April 1918 the First Lord and Rear-Adml. Sir W. R. Hall proceeded to Malta and made arrangements for the entire reorganization of the C.-in-C.'s staff, leading to a great reduction in shipping losses in the Mediterranean.

With the advent of peace the naval staff was greatly reduced, and some divisions naturally disappeared. A change of some importance has taken place in the function of the A.C.N.S., who has become responsible for all staff questions relating to technical branches and crafts such as gunnery, torpedoes and mining. Gunnery and torpedo divisions have been introduced into the staff to deal with questions of the tactical use of these weapons and the training of personnel. The plea for this lies in the close connexion between the use of the weapon and operations. There can be no doubt that training and the tactical aspects of weapons constitute a sphere common to the naval staff, the great technical departments and the fleet, but though they certainly require to be in close touch with the naval staff it still remains a moot point whether all technical crafts with the training that belongs to them should not be segregated from the naval staff.

The distribution of the naval staff in 1921 was as follows:—

1st S.L. and C.N.S.

- D.C.N.S.
  - Intelligence
  - Operations
  - Plans
  - Local Defence
  - Trade
  - Training and Staff Duties
- A.C.N.S.
  - Tactical Section
  - Air Section
  - Gunnery Division
  - Torpedo Division
- Secretariat and Staff Registries.

The duties of the C.N.S. and principal officers are as follow:—

C.N.S.—All large questions of naval policy and maritime warfare organizations, distribution, and fighting sea-going efficiency of the fleet. Advice as to general direction of operations of war. Internal organization and general direction of the work of the naval staff and coöperation of the naval staff with the material side of the Admiralty.

D.C.N.S.—Operations and movements, naval intelligence, strategy, policy and plans. Sea-borne trade and international law.

A.C.N.S.—Methods of fighting at sea. Design in relation to policy and tactics. Staff questions of research. Air development in relation to naval warfare.

Little has been said here of the civil side of the Admiralty because it runs through and interpenetrates every branch. The more essentially civilian branches, such as naval stores and victualling, were among the most efficient of the war. There is sometimes a tendency to talk of the Admiralty as a place where, through civilian agency, the best naval plans "gang aft agley." This is a complete fallacy. Admirals have played a great part in the Admiralty and in its history, past and present, and cannot dissociate themselves from its work. If the Admiralty in the war made mistakes, the navy and its admirals must share the blame, and in the final victory a portion of the laurels belong to the Admiralty and the civil servants of the King.

The strength of the naval staff divisions and departments in the British Admiralty is shown, as for the crucial dates under the war reorganization, in the table on p. 10. (A. C. D).

United States.—After 1909 various measures providing for a reorganization of the U.S. Navy Department were brought forward, but for several years Congress failed to take any action, though certain proposals, notably the recommendations of the board appointed by President Taft in 1909, were strongly urged. The organization of the Department as then constituted had been the subject of criticism by a number of secretaries of the navy as well as by others; the chief defect was the lack of some agency to perform the functions of a general staff in the conduct of naval operations. It is true that since 1900 the secretary had had the deliberations and reports of the general board to guide him, but this board had no executive powers, and in the last analysis the responsibility for coördinating the activities of some eight different bureaus rested solely on the secretary of the navy. In default of legislation, Secretary Meyer made an effort in 1913 to remedy this condition by the issuance of regulations providing for the appointment of an aid for operations, an aid for personnel, an aid for material, and an aid for inspections, who were to be officers of the navy on the active list not below the grade of captain and who were to constitute an advisory council charged with the duty of promoting effective coöperation in the work of the Department. Under Secretary Daniels, who succeeded Secretary Meyer in 1913, the offices of aid for personnel and aid for inspections were discontinued, but there was created the office of aid for

education, whose duties were concerned with the Secretary's programme for furnishing free instruction to enlisted men.

The outbreak of the World War gave new force to the proposals for reorganizing the naval administration, and by the Act of March 3 1915 Congress created the office of chief of naval operations, the incumbent of which by the subsequent Act of Aug. 29 1916, was promoted to the rank of admiral and assigned 15 officers above the rank of lieutenant-commander of the navy or major of the marine corps as assistants. The chief of naval operations was "charged with the operations of the fleet and with preparation and readiness of plans for its use in war." By regulation his duties were defined as including the direction of all strategic and tactical matters, organization, manoeuvres, target practice, drills and exercises and the training of the fleet for war. Under his direction were also placed the Naval War College at Newport, the office of naval intelligence, the office of gunnery exercises and engineering performances, the operation of the radio service and other systems of communication, the aeronautics service, the division of mines and mining, the naval defence districts and the coastguard when operating with the navy. The duties of the previously existing bureaus were limited to activities subordinate to military operations. By the Act of June 30 1914, these bureaus had been reduced to seven, the bureau of equipment having been abolished and its duties distributed among the other bureaus. The value of the new method of organization became almost immediately apparent; within 10 months after the passage of the first Act (1915) plans for the mobilization of the U.S. naval force were approved and ready to put into effect. Thus, when the United States entered the World War the Navy Department was, from the administrative standpoint, well prepared to undertake its new duties and responsibilities. In his report for 1918 Secretary Daniels stated that the war had necessitated no change in the organization of the Department, which had easily expanded to meet the emergency. During the war the Navy Department had the assistance of the War Industries Board, the Council of National Defense, the National Research Council, the Aircraft Production Board and the Naval Consulting Board.

The Naval Consulting Board, composed of civilian inventors and engineers, was first established in 1915 with Thomas A. Edison as chairman. It was a voluntary body whose function was to give expert advice when called upon. Secretary Daniels also established an advisory council composed of the Assistant Secretary of the Navy, the chief of naval operations, the chiefs of bureaus, the major-general commandant of the marine corps and the judge-advocate general of the Navy Department.

Secretary Daniels' interest in education for enlisted men has already been noted. An order issued by the Navy Department in Dec. 1913 provided for instruction of enlisted men, petty officers and warrant officers serving on board ship, the purpose being partly to supply deficiencies in school training and partly to fit them for promotion. Training was also instituted at the various naval stations, and schools for assistant paymasters, yeomen, cooks, bakers, commissary stewards, hospital apprentices, machinists' mates, musicians, mess attendants, painters, plumbers, electricians, blacksmiths, and carpenters were maintained. Thus enlisted men could prepare themselves to engage in civil trades at the end of their period of navy service. With the outbreak of the war much of this educational work was temporarily suspended. By the Act of Dec. 20 1917 the number of midshipmen at the U.S. Naval Academy was fixed as follows—five for each senator, representative and delegate in Congress, one for Porto Rico, two for the District of Columbia, 15 appointed each year at large, and 100 appointed annually from enlisted men of the navy. As a war measure the President was authorized in 1918 to reduce the course of instruction at the Academy from four to three years; in 1919, however, the full four-year course was resumed. During the participation of the United States in the World War three training camps for officers of the marine corps were held. In accordance with the Naval Militia Act of 1914 various states organized divisions known as the U.S. Naval Volunteers to which were assigned naval officers as instructor-inspectors of the militia. A later Act (Aug. 29 1916) created the U.S. Naval Reserve force, with which, in 1918, the naval militia was amalgamated. The Act of 1916 also provided for a Naval Flying Corps, for special engineering officers, for Naval Dental and Dental Reserve Corps, and for taking over the lighthouse service in time of war.

The Naval Appropriations Act of 1915 repealed section 9 of the Personnel Act of March 3 1899, which authorized the retiring of

officers in certain circumstances for the purpose of accelerating promotion. As a result there were no means of promotion in the commissioned personnel of the navy except through vacancies created by death or statutory age-limit retirements. In 1917, however, a new law changed promotion by seniority, so that line officers above the rank of lieutenant-commander were promoted by selection, the question of proved ability being the controlling consideration. Much comment was aroused in 1919 when a new fleet organization was put into effect, by which two divisions of practically equal strength, the Atlantic fleet and the Pacific fleet, each having a commander-in-chief of the rank of admiral, were created. Some critics regarded this as a violation of the principle enunciated by Admiral Mahan that the fleet should never be divided. Secretary Daniels stated that with the Panama Canal open the two fleets could effect a junction in either ocean and "carry out the plans already formulated for operating as one fleet before any enemy could try conclusions with us."

ADOR, GUSTAVE (1845–), Swiss statesman, a member of a family of Vaud, which in 1814 obtained the burghership of Geneva, and grandson of Jean Pierre Ador, who first obtained this right, was born at Geneva Dec. 23 1845. He studied law at the academy (now the university) of Geneva and in 1868 became an advocate. In 1871 he started his political career as member of the communal council of Cologny, and was twice mayor, in 1878–9 and 1883–5. He was a member of the cantonal Parliament 1874–6, and continuously from 1878 to 1915 save for a short break in 1902. In 1878–9 he represented Geneva in the Swiss Conseil des États. Then he became a member of the executive of the canton of Geneva, being put in charge of the Department of Justice and Police. He resigned after an unfavourable election in 1880, but once more became member of the cantonal executive in 1885, and for 12 years had charge of the cantonal finances. In 1889 he became a member of the Swiss Conseil National, and remained so till 1917, being elected its president in 1901. He was president of the cantonal executive in 1890, 1892, and 1896. In 1894 he became lieutenant-colonel in the Swiss army. In 1914 he founded in Geneva the association for facilitating communications between prisoners-of-war and the central Geneva agency, and succeeded in giving this enterprise great importance and a wide-spread extension. After the enforced resignation of Arthur Hoffmann, Ador, in order to soothe the Entente, became a federal councillor or member of the Federal Executive in June 1917 and was entrusted with the Department of Foreign Affairs. Towards the end of 1918 he was elected by Parliament to be the Swiss President for 1919, but retired from the Federal Executive at the end of his year of office.

ADVERTISEMENT (*see* 1.235).—The great public service rendered by advertising during the World War was one of the most striking features of the progress made in this form of business during the decade 1910–20.

Before 1915 no Government in modern times had attempted to raise subscriptions to a loan through the persuasive methods of commercial advertising on a large scale. The custom was merely to publish the prospectus, and leave it to the investor to form his judgment of its merits. It was not till the floating of the 4½% War Loan in 1915 that the British Government took any definite steps to depart from precedent. At an early stage in its subscription, when it was feared that the result would not be as good as had been hoped for, a Treasury official asked the advice of a well-known London journalist, and at his suggestion it was decided to spend £100,000 in advertising under his direction. A little more than £60,000 was actually spent in advertising, and the subscriptions to the loan eventually realized nearly £600,000,000. Later, this new departure was followed, but only after stereotyped official methods had again proved inadequate, in the campaigns for National War Bonds after Dec. 1916, by a considerable extension of advertising, while in the United States it was freely employed in the raising of the Liberty Loans (*see* WAR LOANS PUBLICITY CAMPAIGNS).

Before this, advertising by poster had been employed effectively in England to gain enlistments for the army. In this connexion, and in the loan advertising of 1915 and following years, both in Great Britain and America, advertising reached an effectiveness and power that had never been imagined. It is true that the subject dealt with was in everyone's mind; the appeal was to patriotism, to emotion as well as to cold reason and self-interest. The interests of the writer and of the reader of the advertisements were identical. Even so, the results were amazing. In 1917 a leading American banker said it was impossible to float a loan of $3,000,000,000 because there were "only 275,000 investors in the country." But after widespread advertising there were more than 6,000,000 individual subscribers to this loan, and the amount was greatly over-subscribed. For the last of the American war loans, the "Victory Loan" floated after the Armistice, nearly 21,000,000 subscribers were obtained—one for every five of the country's population, including women and children.

War advertising enlisted much new talent in writing and illustrating. The foremost artists and writers on both sides of the Atlantic volunteered their services and competed for the honour of having their productions used. With professional advertising men, printers, engravers and lithographers all giving their best, the result was an excellence in form and character that had never been achieved before. While the tide of patriotic emotion raised by the war brought new resources to advertising, their proper application would not have been possible without the knowledge gained in advertising for ordinary business purposes during previous years (*see* PROPAGANDA).

In the years before 1915 remarkable advances had been made. The number of articles of trade-marked, advertised merchandise had increased rapidly. Stimulated by advertising revenue, scores of weekly and monthly publications had obtained circulation running into hundreds of thousands, and some had passed the million mark. Great daily newspapers had a similar growth and could afford to sell their copies at a price which did not pay for the paper on which they were printed. Posters and advertising signs had passed from their former rude state to a high degree of attractiveness.

At the same time came a remarkable improvement in the character of advertising. Misleading advertisements and advertising of questionable merchandise or of uncertain financial offers were gradually weeded out. Publications found it unprofitable to accept advertising that was offensive to their better clients. The Association of Advertising Clubs of the World adopted "Truth in Advertising" as their slogan, and vigilance committees were appointed to eradicate misleading or untruthful advertising of whatever products. Advertising had become a business of high principles and well-defined ethics. One of the most powerful influences in the development of advertising along sound business and ethical lines was the advertising agency. Beginning more than half a century before as an agency for the selling of space in publications, the modern advertising agency grew into a service institution, acting on behalf of its clients in planning advertising campaigns, selecting the mediums to be used, preparing advertisements, attending to all the details of engraving, type-setting and plate-making and performing many other incidental services. The advertising agency attracted well-educated young men in increasing numbers and represented a recognized field for the employment of talent.

All advertising is more or less a competition for public attention. As the volume of advertising increased the competition became more keen, and resulted in improvement of both the writing and artistic treatment of advertisements. One of the most notable features in recent years has been the use of illustrations in colour, made possible by improved processes of colour-engraving and by the perfection of high-speed colour printing presses. One popular magazine in America, with a circulation approaching two million, has contained more than 50 full-page advertisements in colour in a single issue. Every one of these pages was printed by four-colour process, and gave a faithful reproduction of the subject. This has made it possible to display all sorts of merchandise, including foods, in their natural tempting colours, and textiles with all their shades and patterns, as well as to reproduce beautiful paintings for their attractive value. Perhaps as a result of this achievement in colour printing, there has been a remarkable improvement in the artistic worth of advertising illustrations. Celebrated painters and illustrators no

longer find it beneath their dignity to make pictures for advertising purposes, especially as the bids for their services run to large figures. Similar improvement has been achieved in typography, engraving and lithography, and in all the mechanical processes of reproduction.

As the volume of advertising expenditure has grown, so has the number of publications which derive their chief support from advertising. These publications have been divided more and more in recent years into groups or classes, each with an appeal to a certain class of the population. The number of general publications reaching all classes has been correspondingly reduced. The most prominent class publications are the women's magazines, chiefly of monthly issue, of which in 1921 there were four or five in America with more than a million circulation. These magazines deal with home problems, dressmaking, cooking, care of children and kindred subjects, and are the most valuable mediums for the advertising of foods, textiles and all household commodities. There are similar class publications devoted to business interests, the world of books, motion pictures, the theatre, fashionable society, sports of one kind and another and all classes of commercial and industrial enterprises. The significance of this tendency is that advertising of each kind may be placed before the readers it especially interests, with a selected audience and less waste of circulation.

Each succeeding year has seen some enlargement of the possibilities of advertising. Paid space has been used in increasingly large amounts in political campaigns, local and national, presenting the records of candidates and showing photographs of themselves and their families. It is used more and more to influence public opinion on behalf of one cause or another. Industrial disputes, involving strikes or lock-outs, have led employers and employees alike to appeal through advertisements to the public for sympathy and moral support. Public service institutions have used advertising to put themselves in a better light before the public or to explain the necessity for increased revenue. In one notable case, advertising was used to turn business away. The American Telephone & Telegraph Co. was seriously affected by the entry of the United States into the World War. It could not obtain the supplies it needed; the Government took thousands of its highly trained workers; and at the same time demands on its service increased enormously. The Company was wise enough to advertise, explaining why its service was deficient, why applicants were kept waiting for installations, and also imploring the public neither to conduct unnecessary conversations over the wires nor to prolong use beyond the time required. Similar advertising was employed by the American railways in the period immediately following their return from Government control to private management, but in this case the explanation of inadequate service was followed by an appeal for higher passenger and freight rates to provide revenue for rehabilitation. During the same period, the Chicago meat-packers, facing threatened Federal action for the further regulation of their activities, entered upon an elaborate advertising campaign to convince the public of their blamelessness.

All these varied developments of advertising have been of the utmost interest to students of economic trends. It is certain that advertising has been largely instrumental in changing buying habits and in introducing many things which have quickly become a part of everyday life. The chief function of advertising is the saving of time. Information, whether as to merchandise or controversial or public issues, can be placed before great numbers of the population almost over night. Public education on any subject can be effected in days or weeks, where years were required by old-fashioned methods of canvassing. For this reason it has been possible to build up entire new industries on advertised products within a short period. In political life, and in financial operations, advertising has served to eliminate the secrecy and ignorance which invite deceit and fraud. The whole tendency is to take the public into confidence and play the game in the full light of fair and frank publicity. Advertising is no weapon for dark causes and no advocate for unworthy goods. To be effective it must be a sincere expression of the character of the advertiser. Unless it bears the stamp of truth and sincerity it is ineffective and defeats its own purpose.

This individuality of a business house as well as the conditions under which it operates and the field from which it may seek custom must all be considered carefully before embarking on an advertising campaign. It is well to seek the expert assistance of an advertising agency of established reputation. The implements of advertising are many, including newspapers, weeklies, magazines, trade publications, outdoor displays, cards in railway cars and the sending of circulars and booklets to persons whose names have been selected on some sound principle. Each is more efficient for one purpose than another, and knowledge and judgment are needed to plan a campaign that will achieve results at economical cost. The advertising policy of a business house and the selection of an advertising agency and advertising manager should be a concern for the executive heads who direct the permanent interests of the business. For advertising, once entered upon, is a continuing influence. The advertising for any one week or any one month, unlike that week's or month's buying or selling, cannot be regarded as a completed transaction. Advertising, it already has been said, is an expression of character. It reveals the character of the advertiser, and immediately begins to form a consciousness of the particular house or merchandise advertised in the mind of the public. It has an influence also on the advertiser's own organization. The workman in the factory and the salesman in the shop judge from the advertising their employer's sincerity and desire to serve. If the advertising is such that they can take pride in it; if it is attractive in appearance; if it is placed in the right environment; if it is a worthy representation of the purposes and ideals that animate the business—then the advertising will stimulate every employee to greater efforts and enhance the *moral* of the organization. Every advertisement tends to create or destroy the one great business asset, reputation.

The steady growth of advertising is assured. While there are no authentic data on the amount spent for advertising, it has been estimated that the expenditure for all forms of advertising in America in 1920 was upwards of $1,200,000,000, an increase of approximately 100% in five years. Individual industrial firms in Great Britain spend as much as £200,000 a year on advertising, and the total expenditure there on all forms of publicity is estimated at over a hundred million sterling annually. With the growth in public intelligence and the realization of the power of advertising, it is likely to be still more widely employed in the future. The modern business concern is adopting advertising as a part of its fixed business policy; not as an expedient for occasional use but as an element of business to be constantly employed.

AEHRENTHAL, ALOYS LEXA VON, Count (1854–1912), Austro-Hungarian statesman (*see* 3.25; 9.951), was born at Gross-Skal, Bohemia, the son of Baron (Freiherr) Johann Lexa von Aehrenthal and his wife Marie, *née* Countess Thun-Hohenstein, and began his diplomatic career in 1877 as attaché to the Paris embassy under Count Beust. He went in 1878 in the same capacity to St. Petersburg, and from 1883 to 1888 he worked at the Foreign Office in Vienna under Kalnoky, with whom he formed close relations. In 1888 he was sent as councillor of embassy to St. Petersburg, where he exercised considerable influence with the ambassador, Count Wolkenstein. Recalled in 1894 to service in the Foreign Office, he undertook important duties, and in the following year went to Bucharest as ambassador. Here he succeeded in strengthening the relations between the courts of Vienna and Bucharest, the secret alliance which King Charles had concluded in 1883 with the Central European Powers being renewed on Sept. 30. In 1899 he became ambassador in St. Petersburg, where he remained until his appointment as Foreign Minister in Oct. 1906. Aehrenthal at this time thought that Austria-Hungary must, even at the cost of some sacrifice, come to an agreement with Russia. In this sense he endeavoured to continue the negotiations successfully begun by his predecessor, Prince Franz Liechtenstein (b. 1853), for the bridging over of the differences on Balkan questions

between Vienna and St. Petersburg, in order to create a basis for a permanent friendly relation between Austria-Hungary and Russia. He played a principal part in concluding the Mürzsteg Agreement of 1903. During the Russo-Japanese War he took a strong line in favour of a benevolent attitude on the part of the Vienna Cabinet towards Russia. When, in Oct. 1906, he succeeded Count Goluchowski as Foreign Minister he at first maintained the views which he had professed as ambassador. He was determined to preserve the interests of Austria-Hungary in the Balkans, but also showed himself prepared to meet the Russian wishes in the Dardanelles question. Accordingly he entered into negotiation, after the outbreak of the Young Turk revolution in the summer of 1908, with Isvolski, arranging with him Sept. 15 at the château of Buchlau, in Moravia, an agreement which aimed at securing for Austria-Hungary the annexation of Bosnia and Herzegovina and for Russia the opening of the Dardanelles to Russian warships.

It was only when Isvolski's proposals were wrecked on the opposition of England, and the Russian minister protested against the annexation of Bosnia and Herzegovina, which had meanwhile been accomplished, and supported the Serbs in their opposition to Austria-Hungary, that Aehrenthal abandoned the idea of a friendly accommodation with the Russian Government. In the sharp struggle during the annexation crisis, not only with Russia and Serbia, but with the Western Powers, he held with tenacious energy to his purpose, and, powerfully supported by Germany, succeeded in carrying out his intentions after excited negotiations which threatened to lead to war. The annexation of Bosnia and Herzegovina was acknowledged by the Powers; an agreement was reached with Turkey; Serbia, after long hesitation, was obliged to submit. For this achievement Aehrenthal was rewarded by his master by elevation to the rank of Count (Aug. 18 1909), while at the courts of his opponents he was hated but respected.

This was the zenith of his political career. Few at this time realized the danger which arose later from the closer adhesion of Russia to the Western Powers, especially as Aehrenthal took the greatest pains to prove in all quarters, after the conclusion of the annexation crisis, that Austria-Hungary cherished no far-reaching plans of conquest. In this spirit he offered the most decided opposition to those circles at the court of Vienna which advocated a bloody reckoning with Serbia. He held fast by the Triple Alliance, for he saw in this the surest bulwark of peace. He sought to form the most intimate relations with the German Empire, but insisted on the independence of the Habsburg Monarchy, and energetically repulsed all efforts on the part of the German chancellery to set limits to that independence. One of his most difficult tasks was to adjust the ever-recurring conflicts with Italy, who, while officially supporting the political action of the Triple Alliance, often embarked on courses directly opposed to the interests of Austria-Hungary. A succession of agreements which he concluded with the Italian Foreign Minister, Tittoni, justified his efforts, and enabled him to maintain correct relations with the Italian Government. Yet, by the maintenance of his peace policy, which had the full approval of the Emperor Francis Joseph, he came into serious conflict with the party led by the chief of the general staff, Conrad von Hötzendorf, which championed a policy not afraid of energetic, warlike methods. The battle, carried on on both sides with tenacious endurance, ended in 1911 with the victory of Aehrenthal and the resignation of Hötzendorf.

In the solution of questions of internal policy Aehrenthal, as Foreign Minister, only took part in so far as they seemed to him to affect the interests of the monarchy as a whole. With the Czechs, who on his accession to office had shown some suspicion on account of his intimate connexion with the leading members of the loyal Bohemian landed aristocracy, he succeeded in maintaining reasonably good relations. As against the Magyars, he upheld the view that the unity of the monarchy must not be shaken, and he therefore offered a determined resistance to the attempts of the party of independence to intrench on the rights of the Crown in military matters. He realized the need for an increase of the army and the reorganization of the army and navy, but he opposed the far-reaching demands of the War Minister and the chief of the general staff.

Aehrenthal married in 1902 Pauline, Countess Széchényi. He died Feb. 17 1912.

Even during his lifetime the estimate of his political policy fluctuated violently. On the one hand it was blamed as provocative, on the other as weak. After the disastrous result of the World War, bringing with it the downfall of the Habsburg Monarchy, it is still more difficult to answer the question whether the path pursued by Aehrenthal in foreign affairs was the right one. It is certain that the Entente Powers were drawn more closely together by the active part played, during his period of office, by Austria-Hungary in Balkan affairs. It is true that the chances of success for the Central Powers in an international struggle were better in the years 1909 and 1911 than in 1914. But the question remains undecided whether, if his activity had been longer continued, Aehrenthal would have been able to maintain the position of Austria-Hungary as a great power without an appeal to the decision of arms. There is no doubt that Aehrenthal was a statesman of considerable mark, a man of wide knowledge and well-ordered intelligence; he was ambitious, but not vain, and an untiring worker. Moreover, in moments of great excitement he was able to maintain outward calmness. He was convinced of his own value, but had no desire to parade it. The Emperor Francis Joseph esteemed him, stood by him in the good and evil hours of his administration of foreign affairs, and repeatedly refused to accept his tendered resignation.

See B. Molden, *Alois, Graf Aehrenthal: Sechs Jahre auswärtiger Politik Oesterreich-Ungarns* (1917); and the article "Aehrenthal" in the *Deutsche Nekrologen* (vol. xviii., 1917, pp. 230 *seq.*).

(A. F. Pr.)

AERONAUTICS (*see* 1.260).—Between 1909 and 1921, Aeronautics, an infant to start with, had not grown as a child grows, but irregularly. One member had prospered at one time and one at another. Thus we find that enterprize in flight was early in advance of all appliances; then engines developed for a period; later, structural design. Though aerodynamic theory had been far ahead it was badly neglected for a spell and was once again fostered; with this study secret and semi-magical wing shapes disappeared; after that came methodical production, first in units and subsequently in bulk; then came pilotage and the elements of commercial flying. The seaplane, though less risky than the aeroplane, advanced even more fitfully and never caught it up; the airship, which was earlier and safer, still lagged behind because it made less appeal to sensation and cost much more. The engine, though once in advance, fell behind, and only now (1921) is again full of promise. Landing-grounds and night alighting facilities have advanced but little, meteorology progresses slowly against fog, the enemy, but aerial navigation is at last appearing as a science.

By taking such of these elements as have separate stories and keeping them distinct in the several sections which follow, it is hoped to present more clearly the progress and prospects of aerial science than by showing a series of moving pictures of the infant prodigy in motion as a whole.

Achievements and Performance (*see* Section I.).—The twelve years of labour of the American Wrights culminated just before 1909 in the birth of the art as we now know it. Hazardous flights on the straight or in figures of eight; a circle over Paris; the crossing of 24 miles of sea; the excelling of the speed of an express train, a velocity once deemed monstrous and now insignificant; the scaling of the Alps; looping and inverted flying; leaving the craft by parachute; releasing the first 1,000-lb. weight; firing the first gun; discovering how to get out of a spin; alighting by night, etc.—each of these was an experience and a token of growth. Each seemed perilous and astonishing, yet they had become so common by 1921 that it was already difficult even to remember the sense of wonder.

Design (*see* Section II.).—The advance of design occurred away from the public vision, nor were its milestones of progress coincident with the landmarks made by the great performers who relied more on their own tact in the air than on the tested and thought-out qualities of their craft. They chafed under the cautions of those who made stress calculations. Each "stunt" was performed before any human being knew if it was safe. How and why was design altered

and bettered under the circumstances? Yet strength factors were introduced, down pressures foreseen, fine lines provided, wing shapes and controls improved, alighting gear developed and instability cured. This is the subject matter of Section II. which is closely allied to Section III.

Aerodynamics (*see* Section III.).—Aerodynamic theory had risen out of the void at the bidding of the applied mathematician before 1909, but it developed at the call of designers who would have been tied to the repetition of old methods had not theory justified departure. Once aerodynamic theory was established their inspiration could take wing.

The deductions[1] from wind tunnel experiments on models 2 ft. long could be but surmises till the principle of dynamic "similarity" emboldened designers to transfer the wind tunnel results to the 40-ft. machines. "Scale effect," "slipstream effect," pressure distribution, phugoids, and the like, had to be verified on the full-sized aeroplane and measured in the course of flight with the coöperation of a few keen fliers, at a time when pilots at large were almost antagonistic to "theory." Mathematics had been applied to the motion of aeroplanes through the air in advance of even the earliest flight, and several separate starts were made. England, represented by F. W. Lanchester, was easily first. Lanchester made great strides, at a time when he had no wind channel for his model verifications. Bryan came independently; L. Bairstow had the wind tunnel, of which he has indicated the arrangement in Section VI. and greatly advanced the problems. It was E. T. Busk who in 1913 in his own person as flier verified the theories he had formed and achieved stable flight on "RE 1" (*see* Plate I., fig. 1). America had led in initiating practical flight; France in model experiments, rotary engines and speed records; Germany in length of aeroplane flight and in rigid airships; but in the matter of stability and of scientific analysis on both model and full scale, Britain took the lead before the war and still kept it in 1921. Something of each national temperament is disclosed by these specializations.

Construction and Materials (*see* Section IV.).—Aircraft constructional methods are to be regarded from two points of view—the one where a few craft are to be made as perfect as possible, and the other where bulk production is demanded.

Before 1914 there was no output of aircraft in Britain other than by units; in France there was some manufacturing, in America a little, and in Germany rather more. These countries had factories proper where repetitive processes were employed. An army, small in numbers, was deemed in Britain to need correspondingly few aircraft. A large navy neglected them. When bulk production came it came with a will, but designs that were admirable for unitary construction were found ill adapted to bulk manufacture, and the British story of changes in material and methods which is outlined in Section IV. is typical of the war period everywhere.

The tautening of fabrics with cellulose acetate, the evolution of the fairshaped strut and wire, the steerable tail skid, sewing the fabric to the wing ribs, covering the wheel spoke with fabric, were among the step-by-step advances which all belong to the period before large outputs were contemplated, *i.e.* the period when, for example, joints were machined from the solid steel bar. The plywood body, the spars of built-up wood, the standard relation of radiator to engine size, the pressed metal turnbuckle and the thorough interchangeability of detail parts belong to the "bulk output" period, as also incidentally much speeding-up of processes and methods, the evolving of glues and cements, fine castings, new alloys and the widespread use of tests not hitherto commercialized but known to be good by the few. It would be truer to say that the World War disseminated the science of aeronautics rather than that it fostered it. The war did foster the technics of quantity production.

Aero Engines (*see* Section V.).—Man would have flown long before he did but for the lack of a light engine. One cwt. per horse-power was about the weight of the commercial gas engine, and to fly he wanted one twenty times lighter. The French rotary engine of 1909–10 was the most real promoter of aerial experience of its time, for it weighed 4 lb. where a motor-car engine weighed ten. How and by what grouping of parts, increases of compression and refinements of design this weight has been cut down to 2 lb. with fuel economy on a similar scale, appears in Section V. Here it will only be noted that the Germans on the basis of airship experience had inclined rather earlier than others to big powers on aeroplanes, and their aeroplane successes on aerodynamically inferior craft were due to big engines. Their engines were water-cooled, rather heavy but reliable. The radial air-cooled engine of the French has been mentioned above. The British service was late to realize how very big the war aero engine must be, and developed an air-cooled, non-rotary and some good water-cooled motors eventually of adequate sizes. The Americans made good use of the experience poured in upon them from Europe when they began in 1917 to tackle the Liberty engine of 450 H.P. Apart from size, the advances in view to-day are considerable. The means for protecting ourselves from the fire risks on crash due to petrol are also being evolved.

Navigation (*see* Section VI.).—Aerial navigation, as distinct from piloting with the ground in view, developed tardily everywhere, though first in Britain. It was a surprise to find that raiding airships from Germany disclosed no up-to-date navigating apparatus when they were brought down, nor had their aeroplanes any turn indicator to guide them when immersed in cloud or fog. Even after seeing the Lucas compass (*see* Plate I., fig. 2) on captured aeroplanes they did not appreciate or copy it, nor its principle of the "space-damped" vertical card, spherical bowl and long period; nor was there anywhere an instrument to compare with the British apparatus figured in Section VI. The air speed indicator that uses the principle of Pitot was also a British idea, which displaced the earlier French flat plate pressed back by the wind against a spring, and other such speed-meters.

Control of Air Traffic and Air Stations.—Air stations and the rules evolved to control traffic have a section (VII.) to themselves. The early stations were fields and each flier a law to himself. When the Air Convention of Oct. 1919 is ratified all aircraft will be taboo that have not a specific factor of strength and an adequate field of view for the flier. As we progress all stations will give wireless warning to those approaching them when they are immersed in fog and will afford facilities for night alighting. The movement is in this direction. The mobility of aircraft makes international agreement on all rules for alighting, racing, and signalling warnings very important. Bodies like the Royal Aero Club in Britain exist in each county and meet annually for these purposes.

Seaplanes (*see* Section VIII.).—The seagoing seaplane is relatively backward. To make a craft light enough to fly and heavy enough to stand the buffets of the open sea up to the speed needed to quit the waves in flight is a problem which was not fully solved even under the war stimulus. It was tackled too late—by Britain no less than the others. Even the high-speed "float" seaplane was neglected in England but it eventually advanced in Germany to be a formidable offence against the air enemies of the submarine. Theirs was not, however, a craft that could ride out a sea. The American NC3 made a record by riding on the water for 150 miles in its Atlantic crossing. It was an achievement to withstand the sea so long even though the craft was travelling backwards all the 150 miles. Section VIII. shows that scientific work is being applied to the problem, notably in the matter of stability when changing from waterborne to airborne conditions.

Airships (*see* Section IX.).—Airship knowledge gave to Germany technical advantages which would have been even more valuable to Britain. They did not use on aeroplanes the identical engines of their airships, but the experience of large aero engines of the utmost reliability and economy was there. The dominant advantages of airships are that they fly for long hours, carry large weights, do not descend for an engine failure and can safely fly by night. In consequence of night flying they are able on long journeys to outstrip the aeroplane in speed from point to point. High cost of housing and the numbers required to handle them on the ground were their chief hampering factors, but the wonderful development of the mooring mast, a British device, has improved the position. The towing of airship by airship and by submarine, the protection of fabric from deterioration, the use of non-inflammable gas are all landmarks in their evolution. The kite balloon and the parachute also need mention, though opinions differ as to the advisability of giving the latter to the commercial aeroplane as a life-belt is given to the liner. It is of little use unless the jump is made over 200 ft. from the ground; if a high wind is blowing the parachutist meets the ground with the sideways speed of the wind and it absorbs 18% of the useful (passenger) load. This position is, however, the result of great advances which have assuredly not ceased.

Each sectional aspect of aeronautics between 1909 and 1921 divides itself into three periods: before, during and after the war. The dominant emotions and aspirations of those periods governed men's thoughts whether they were flying, designing, calculating; experimenting with engines, model aeroplanes or safety devices; evolving navigational instruments, tests for pilots against giddiness, or parachutes to save the lookouts on kite balloons. Before the war the aircraft builder starved although it was early accepted that frontiers, rivers, chasms, forests and entrenched positions could be crossed by anyone brave enough to fly, but that acceptance was half-hearted. It now amazes one to realize that in 1911 the speed of flight was regarded as a defect for the military aeroplane, or that vulnerability by gun-fire from the ground was its supposed weakness. The Governments demanded that their aeroplanes should be transported in crates, or towed with folded wings to their jumping-off place (*see* Plate I., fig. 3). An aeroplane was a mute observer; no means of continuously transmitting observations—say of artillery fire or enemy movements—or for making photographic records had been tried out, accepted as good or prepared in quantity. Imagination is greater than fact when the imagination is active: all these effects could easily be, and were, imagined once flight was admitted—but the state is a herd, and extends its imaginative power like a herd to the distance of the next meal or next year's crop. All nations econo-

[1] *See* "Flight," 1912, pp. 32, 33.

between Vienna and St. Petersburg, in order to create a basis for a permanent friendly relation between Austria-Hungary and Russia. He played a principal part in concluding the Mürzsteg Agreement of 1903. During the Russo-Japanese War he took a strong line in favour of a benevolent attitude on the part of the Vienna Cabinet towards Russia. When, in Oct. 1906, he succeeded Count Goluchowski as Foreign Minister he at first maintained the views which he had professed as ambassador. He was determined to preserve the interests of Austria-Hungary in the Balkans, but also showed himself prepared to meet the Russian wishes in the Dardanelles question. Accordingly he entered into negotiation, after the outbreak of the Young Turk revolution in the summer of 1908, with Isvolski, arranging with him Sept. 15 at the château of Buchlau, in Moravia, an agreement which aimed at securing for Austria-Hungary the annexation of Bosnia and Herzegovina and for Russia the opening of the Dardanelles to Russian warships.

It was only when Isvolski's proposals were wrecked on the opposition of England, and the Russian minister protested against the annexation of Bosnia and Herzegovina, which had meanwhile been accomplished, and supported the Serbs in their opposition to Austria-Hungary, that Aehrenthal abandoned the idea of a friendly accommodation with the Russian Government. In the sharp struggle during the annexation crisis, not only with Russia and Serbia, but with the Western Powers, he held with tenacious energy to his purpose, and, powerfully supported by Germany, succeeded in carrying out his intentions after excited negotiations which threatened to lead to war. The annexation of Bosnia and Herzegovina was acknowledged by the Powers; an agreement was reached with Turkey; Serbia, after long hesitation, was obliged to submit. For this achievement Aehrenthal was rewarded by his master by elevation to the rank of Count (Aug. 18 1909), while at the courts of his opponents he was hated but respected.

This was the zenith of his political career. Few at this time realized the danger which arose later from the closer adhesion of Russia to the Western Powers, especially as Aehrenthal took the greatest pains to prove in all quarters, after the conclusion of the annexation crisis, that Austria-Hungary cherished no far-reaching plans of conquest. In this spirit he offered the most decided opposition to those circles at the court of Vienna which advocated a bloody reckoning with Serbia. He held fast by the Triple Alliance, for he saw in this the surest bulwark of peace. He sought to form the most intimate relations with the German Empire, but insisted on the independence of the Habsburg Monarchy, and energetically repulsed all efforts on the part of the German chancellery to set limits to that independence. One of his most difficult tasks was to adjust the ever-recurring conflicts with Italy, who, while officially supporting the political action of the Triple Alliance, often embarked on courses directly opposed to the interests of Austria-Hungary. A succession of agreements which he concluded with the Italian Foreign Minister, Tittoni, justified his efforts, and enabled him to maintain correct relations with the Italian Government. Yet, by the maintenance of his peace policy, which had the full approval of the Emperor Francis Joseph, he came into serious conflict with the party led by the chief of the general staff, Conrad von Hötzendorf, which championed a policy not afraid of energetic, warlike methods. The battle, carried on on both sides with tenacious endurance, ended in 1911 with the victory of Aehrenthal and the resignation of Hötzendorf.

In the solution of questions of internal policy Aehrenthal, as Foreign Minister, only took part in so far as they seemed to him to affect the interests of the monarchy as a whole. With the Czechs, who on his accession to office had shown some suspicion on account of his intimate connexion with the leading members of the loyal Bohemian landed aristocracy, he succeeded in maintaining reasonably good relations. As against the Magyars, he upheld the view that the unity of the monarchy must not be shaken, and he therefore offered a determined resistance to the attempts of the party of independence to intrench on the rights of the Crown in military matters. He realized the need for an increase of the army and the reorganization of the army and navy, but he opposed the far-reaching demands of the War Minister and the chief of the general staff.

Aehrenthal married in 1902 Pauline, Countess Széchényi. He died Feb. 17 1912.

Even during his lifetime the estimate of his political policy fluctuated violently. On the one hand it was blamed as provocative, on the other as weak. After the disastrous result of the World War, bringing with it the downfall of the Habsburg Monarchy, it is still more difficult to answer the question whether the path pursued by Aehrenthal in foreign affairs was the right one. It is certain that the Entente Powers were drawn more closely together by the active part played, during his period of office, by Austria-Hungary in Balkan affairs. It is true that the chances of success for the Central Powers in an international struggle were better in the years 1909 and 1911 than in 1914. But the question remains undecided whether, if his activity had been longer continued, Aehrenthal would have been able to maintain the position of Austria-Hungary as a great power without an appeal to the decision of arms. There is no doubt that Aehrenthal was a statesman of considerable mark, a man of wide knowledge and well-ordered intelligence; he was ambitious, but not vain, and an untiring worker. Moreover, in moments of great excitement he was able to maintain outward calmness. He was convinced of his own value, but had no desire to parade it. The Emperor Francis Joseph esteemed him, stood by him in the good and evil hours of his administration of foreign affairs, and repeatedly refused to accept his tendered resignation.

See B. Molden, *Alois, Graf Aehrenthal: Sechs Jahre auswärtiger Politik Oesterreich-Ungarns* (1917); and the article "Aehrenthal" in the *Deutsche Nekrologen* (vol. xviii., 1917, pp. 230 *seq.*).

(A. F. Pr.)

AERONAUTICS (*see* 1.260).—Between 1909 and 1921, Aeronautics, an infant to start with, had not grown as a child grows, but irregularly. One member had prospered at one time and one at another. Thus we find that enterprize in flight was early in advance of all appliances; then engines developed for a period; later, structural design. Though aerodynamic theory had been far ahead it was badly neglected for a spell and was once again fostered; with this study secret and semi-magical wing shapes disappeared; after that came methodical production, first in units and subsequently in bulk; then came pilotage and the elements of commercial flying. The seaplane, though less risky than the aeroplane, advanced even more fitfully and never caught it up; the airship, which was earlier and safer, still lagged behind because it made less appeal to sensation and cost much more. The engine, though once in advance, fell behind, and only now (1921) is again full of promise. Landing-grounds and night alighting facilities have advanced but little, meteorology progresses slowly against fog, the enemy, but aerial navigation is at last appearing as a science.

By taking such of these elements as have separate stories and keeping them distinct in the several sections which follow, it is hoped to present more clearly the progress and prospects of aerial science than by showing a series of moving pictures of the infant prodigy in motion as a whole.

Achievements and Performance (*see* Section I.).—The twelve years of labour of the American Wrights culminated just before 1909 in the birth of the art as we now know it. Hazardous flights on the straight or in figures of eight; a circle over Paris; the crossing of 24 miles of sea; the excelling of the speed of an express train, a velocity once deemed monstrous and now insignificant; the scaling of the Alps; looping and inverted flying; leaving the craft by parachute; releasing the first 1,000-lb. weight; firing the first gun; discovering how to get out of a spin; alighting by night, etc.—each of these was an experience and a token of growth. Each seemed perilous and astonishing, yet they had become so common by 1921 that it was already difficult even to remember the sense of wonder.

Design (*see* Section II.).—The advance of design occurred away from the public vision, nor were its milestones of progress coincident with the landmarks made by the great performers who relied more on their own tact in the air than on the tested and thought-out qualities of their craft. They chafed under the cautions of those who made stress calculations. Each "stunt" was performed before any human being knew if it was safe. How and why was design altered

The Pre-War Years.—The chief flight of the year 1910 was Paulhan's from London to Manchester, by which he won the *Daily Mail* £10,000 prize (April 27 and 28 1910). The race was gallantly contested by Grahame-White. If skill and tenacity had been the determining factor, the prize would have been hard to award. The chances of the race aroused the greatest enthusiasm and to the many incredulous one more demonstration was thus given of the possibilities of the aeroplane.

During the year flying meetings were held at Heliopolis, Wolverhampton, Bournemouth, Blackpool and Lanark, the flying performances at which demonstrated the advance that had been made on those of the previous year. At Bournemouth England lost one of her best fliers, the Hon. C. S. Rolls, who had previously made the double journey across the English Channel. His statue stands at Dover, gazing out over the waters that he crossed. Most British pilots were flying on aeroplanes that were wholly or partly French, but it is to be noted that Moore Brabazon won the British Michelin Cup with a flight of 19 m. on an all-British machine. At Lanark Chavez on a Blériot monoplane reached a height of 1,794 metres, a prelude to his magnificent flight over the Alps, the tragic sequel to which was his fatal accident on landing. Legagneux, however, created a record by reaching a height of 3,100 metres.

Moisant flew from Paris to London but, though he quickly reached English soil, various troubles delayed his arrival in London till three weeks later. On the continent, Leblanc won the £4,000 prize for the *Circuit de L'Est*. Grahame-White went to America and brought back the Gordon Bennett Cup, which Curtis had won the year before. The contests for the British Michelin Cup and the Baron de Forest prize brought forward new fliers. Sopwith, competing for the former, flew 100 m. at Brooklands, which had been opened as a flying-ground the year before, thus beating Cody's distance of 97 m. which had previously stood; competing for the latter he flew from Eastchurch well into Belgium.

At the close of the year Cody, after an exciting contest with Sopwith and Ogilvie, held the British Michelin Cup with a distance of 185 m. in 4 hours 47 minutes. In France Tabuteau held the International Michelin Cup with a distance of 582 km. in 7 hours 48 minutes.

It was in 1911 that the aeroplane was first tried in warfare. Hamilton, an American, carried out a flight over the town of Ciudad Juarez during a Mexican rebellion. In their campaign in Tripoli the Italians also realized the value of the aeroplane for reconnaissance. In England the idea of the time was that, for bombing, aircraft would be useless and contrary to international usage; on the other hand, the first British attempt was made to run an aerial post between Hendon and Windsor.

Capt. Bellenger, a Frenchman, flew from Paris to Bordeaux in 5 hours 10 minutes net time, a distance of 690 km., while later Fourny remained in the air for 11 consecutive hours, covering a distance of 720 kilometres. Garros made a height record of 3,910 metres. London was linked with Paris by a notable non-stop flight by Prier, which foreshadowed the aerial services of to-day.

The year 1911 saw many races: the Paris-Madrid race won by Védrines at 50 m.p.h., in the course of which the French Minister of War met his death and the premier was seriously injured; the European Circuit, divided into nine stages, with the recently opened Hendon flying-ground at the end of the seventh, which was won by Lt. Conneau flying under the name of "Beaumont"; the *Daily Mail* race round Great Britain of 1,010 m., also won by "Beaumont" with Védrines as a close second.

The Gordon Bennett Cup was won for America at Eastchurch by Weyman flying a Nieuport monoplane at 79 m.p.h., and the International Michelin Cup for France at Gidy-Lhumery by Helen with a distance of 1,252 km. in 14 hours 7 minutes at 56 m. per hour.

The increase in performance over the previous year may be referred chiefly to the development of the aero engine. It would be difficult to say that fliers were more skilful, but it is certain that they were able to substitute knowledge and experience for pure instinct, and thus set out on long and arduous flights with increased confidence in their own powers and in the reliability of the aircraft they flew.

One of the most prominent features of the year 1912 was the active part that the British and French Governments took in the development of aircraft for war. The French Minister of War held a great review of military fliers and aeroplanes, and British aircraft took a conspicuous part in naval and military manoeuvres. The Cody pusher biplane won the £4,000 prize in the War Office trials on Salisbury Plain in the summer, during which the tractor biplane BE2 reached a height of 9,500 feet. In Sept. four army fliers lost their lives in two accidents in monoplanes, which led to close restrictions being placed on their method of bracing in England. In March the French Government had imposed a ban on certain monoplanes until the defects were removed as the result of a report by Blériot on their structural weakness.

Garros won the *Grand Prix* of the Aero Club de France for the Anjou Circuit of 685 m. at 45 m.p.h.; Sopwith the first Aerial Derby at 59 m.p.h., a race round London of 81 m.; Védrines the Gordon Bennett Cup in America at 105 m.p.h.; Audemars flew from Paris to Berlin; the two British Michelin Cups were won by Hawker and Cody, the first with a duration of 8 hours 23 minutes, and the second with a flight over a circuit of 186 m. in 3 hours 23 minutes; in France Daucourt for the Pommery Cup flew 550 m. in a single day at 63 m.p.h., while at the meeting at Leipzig Hirth reached a height of 4,100 metres. World's records were made in height by Garros, who reached 5,610 metres; in distance by Fourny with 1,010 km.; and in speed by Védrines with 174 km. per hour, over 5 kilometres.

In the spring, flying had suffered an irreparable loss in the death of Wilbur Wright from typhoid fever.

Apart from the establishment of the fundamental merit of the tractor biplane the year was notable rather for a steady improvement in strength and detail than for any radical departure in type. From this time it becomes increasingly difficult to single out individual performances. Achievements deemed impossible three years before became commonplace events.

The year 1913 was one of great progress. Long cross-country flights were proving day by day the faith that fliers had in the aero engine. Seguin in France covered 1,021 km., Legagneux reached a height of 6,120 metres, while Prévost attained the speed of 203 km. per hour, over 5 kilometres. It was a brilliant year for him; he won the Schneider Cup for seaplanes at Monaco, covering 150 nautical m. in 3 hours 48 minutes, and the Gordon Bennett Cup at Reims at 124 m.p.h. Helen won the International Michelin Cup with a distance of 16,096 km. Captain Longcroft won the Britannia Challenge Trophy by a magnificent flight from Montrose to Farnborough via Portsmouth on a BE2 aeroplane built by the Royal Aircraft factory. Hamel won the second Aerial Derby at 76 m.p.h., while Pégoud in France and England gave some of the most marvellous demonstrations in the new art of aerobatics that the world had ever seen, including looping, inverted flying and quitting his aeroplane in a parachute. In Dec. 1913 the RE1, the first aeroplane stable longitudinally and laterally, was flown for 35 minutes without hand or foot control; and this, which may be regarded as the greatest technical advance in aerodynamics, is to the credit of Busk, an Englishman, who both made the flight and applied the theory on which the aeroplane was designed. The last previous attempt of the kind was by Dunne, who a few months earlier had flown for one minute with "hands off."

The year 1914, just as it marked a turning point in the affairs of nations, altered the whole character of flying. For seven months the ideas of safe, stable flying and safe alighting were dominant; then the World War came down like a curtain and blotted them out in favour of widely different objects. During those months, Sykorsky, in Russia, had been proving the weight-carrying possibilities of the aeroplane, and had risen to 300 metres, carrying 15 passengers. At Farnborough, an SE4 (*see* Plate I., fig. 4) flew at 130 m.p.h. and climbed 1,400 ft. in a minute. Linnekogel had reached a height of 6,350 metres in Germany, though just before the war Oelrich beat him by reaching 7,860 metres. Landmann

in Germany remained in the air for 21 hours 48 minutes, while Boehm further improved on this unofficially with a time of just over 24 hours.

The Schneider Cup for seaplanes was won for England by Pixton, who covered 150 nautical m. in two hours at Monaco on a Sopwith biplane fitted with floats. The Aerial Derby, the London-Manchester-London and London-Paris-London races were all won by Brock. Notable events on the Continent were the Prince Henry Circuit of 1,125 m. in Germany, in which there were 40 competitors, and the Security competition in France; although most of the big international races had to be cancelled.

The World War.—The ingenuity that sought for speed at low heights suitable to the race-course or for the maximum climb was by no one appreciated as vital for war purposes, either in France or Germany, and least of all in Britain; aeroplanes were for reconnaissance—they should fly slowly—and the very inferior anti-aircraft guns would not impede their flying low; it was not till many months elapsed that the margin of speed and climb was found to be decisive as to who should be the victor in mortal combat held in the upper air. The diverse needs of war stimulated the development of specialized types, which were evolved as fast as production considerations would admit. The prime use remained, as foreseen, reconnaissance, but to maintain and support this other craft were called into being; the possibilities of the aeroplane as a bomb-dropper were as yet hardly called for. The early war pilot went into battle armed more as a sportsman than as a soldier. But he was attacked, and had either to be made self-defensive or to be escorted by fast, high-powered, swift-climbing fighters.

In 1915 the artillery on the ground came to rely almost entirely on aerial "spotting," and the small single-seater fighters had to sweep hostile aircraft from the skies to allow such machines fitted with wireless to pursue their work uninterrupted. Bombing was also rapidly developed. The first time a 1,000-lb. weight was released by Gooden from an aeroplane was an event calling for a special communication to the Secretary of State that by big bombs the nerves and arteries of the enemy might be continually harassed and disorganized. Owing to freedom of movement in three dimensions air supremacy was a far more difficult and comprehensive thing than naval supremacy. It was never achieved save locally and for brief periods by any Power, and then only by concentrating organizations of the greatest mobility and flexibility at some place and time.

The requirements of quantity, coupled with the demands for change, came so rapidly that the development and expansion of the aerial arms of the Great Powers are difficult to grasp. Of the innumerable acts of courage, the endurance and self-sacrifice, the skill of the pilot in war, it is impossible here to attempt a record. Here and there the names of great pilots stand out. But if one be mentioned, a hundred others would claim justice. Such were the changing fortunes of war, so many and so astounding were the feats of daring, that with deeds not unworthy of a Ball, a McCudden, a Bishop, a Nungesser, a Garros, a Guynemer, a Védrines, an Immelmann, a Richthofen, a Boelcke or a Voss, many a flier passed through the war without fame or praise.

It was only during 1915 that the specialized type of aeroplane began to appear. The two-seater aeroplane with an engine of up to 150 H.P. was used promiscuously; for reconnaissance, artillery "spotting," any bombing there was, and fighting as well. Types in use by the British were BE2C's, Avros and Blériots, with small engines below 100 H.P.; by the French, Caudrons, Breguets, Farmans, Voisins, Blériots and Moranes; by the Germans, LVG's and Rumplers, with engines over 120 H.P. and up to 160 H.P.; the maximum speeds seldom exceeded 80 m. per hour. Later in the year the single-seater, originally intended as a scout, was used for fighting. The 80 H.P. Bristol scout and other tractors used by the British were handicapped by their inability to fire forwards, the direction of best aim; the various models of Nieuport and Morane scouts used by the French were also adopted by the British, while the Albatross and Fokker scouts were used by the Germans. Engines up to 200 H.P. were coming in. The so-called "scout" became a real fighter; its speed and climb became truly effective when firing through the propeller was devised by a Frenchman, adopted by Germany, and then with feverish haste by the Allies. The French and Germans, more zealous about bombing, were for this purpose introducing large twin-engined aeroplanes and experimenting with armoured ones. Speeds rose to over 100 m.p.h., and aeroplanes flew and fought at heights of 15,000 ft., whither they were driven by the increasing intensity of the anti-aircraft fire and by the advantage to be derived from a swift descent to pounce or to retract. Night flying, which had been tentatively practised for exhibition before the war, was taken seriously, as its potentialities for bombing, for the depositing of spies and for other conveyance were realized. Stable aeroplanes with special alighting gear and a clear forward field of view were needed for the repelling of airships by night. The loading of war aeroplanes was increased and was only limited by the absolute necessity of reasonable landing speeds; even then fast scouts taxed the skill of most pilots. Seaplanes, whose aerial performance was always poor compared with that of aeroplanes, were of great use in conjunction with naval operations, and took part in the Gallipoli campaign.

In 1916 the air services came more and more into prominence. The cry for higher and yet higher performance was insistent. The French Spad flew at 130 m.p.h. and reached over 20,000 feet. The German Albatross scouts manoeuvred magnificently at great heights, and high-flying reconnaissance Rumplers with cameras photographed back areas. Bombing flights up to 800 m. were carried out, notably by the French. Night bombing and even night reconnaissance became general, first on moonlight, and then, as the flier's skill increased, on dark nights. Accessories for night flying, such as wing tip flares, were developed. Airships had already proved vulnerable to aeroplane attack, and a German airship was brought down in flames at Cuffley on Sept. 3 1916 while engaged in raiding England by night. Kite balloons were attacked and brought down with incendiary rockets and bullets. Flying became organized, and aeroplanes patrolled in larger and larger formations and in layers, each unit being allotted its respective duties, signals being made by coloured lights. Slower aeroplanes were escorted by fast fighters; other fighters, like hawks, moved on mobile offensive patrols.

As peace seemed no nearer in 1917, redoubled efforts were made in the air. America joined in, and American fliers joined British squadrons, finally forming their own; the Italians had developed large twin-engined Caproni triplanes; the Austrians, the Turks, all realized what air-power meant. The British used large twin-engined flying-boats against the submarine. The Germans eventually attacked with big float-seaplanes of remarkable speed. Scouts were flown off lighters at sea against airships, and off the decks of battleships and "mother" ships. Formation flying was developed and aerial fighting of the fiercest intensity was the prelude to every big land operation. The British SE5A's and Sopwiths, the French Nieuports and Spads, the German Albatrosses, Rolands and Fokkers, swept the sky in "circuses" 30 strong, and the effect of superiority of performance was hard to distinguish from sheer skill in handling.

As the last and bitterest struggles of the World War were being waged in 1918, aerial activity reached its zenith. The deep hum of aircraft practically never ceased by night or day, in fair weather or foul. Large twin-engined Handley Pages and German Gothas flew farther and farther afield on bomb raids; retreating armies in the East fled before the onrush of death from the air. Aeroplanes flew low and attacked anything they could find on the ground. Large flying-boats patrolled vast expanses of water. The night was full of the attackers and the attacked, for fighting scouts had learnt to seek out and fight the night bomber. Engines had become more and more powerful and had reached 400 horse-power. The height at which an aeroplane could fly was limited rather by the physical endurance of the pilot, even with the help of oxygen, than the possible "ceiling" of the aeroplane. It would hardly be an exaggeration to say of the aeroplanes used in the first and last phases of the World War that their relative effectiveness as fighting implements was commensurate with that of a bow and arrow and a modern rifle.

The Art of Flying in War.—If, in war, higher performance was the prime means of gaining the position to strike, controllability was essential to direct the blow. Pégoud had given a glimpse of the possibilities of aerobatics in 1913, and during the war these possibilities were explored to the uttermost. Probably owing to temperament, the French led the way. The pilot of a fighting aeroplane simply came to regard his machine as a mobile gun platform, whose motion must be in sympathy with his lightest touch to enable him to get his sights on the target. In fighting-scouts the guns were integral with the aeroplane, the nose of which was controlled so as to point them at the target. With opposing machines of equal performance the striking position had to be gained by manoeuvre, confidence in which was inspired by a good view of the opponent. In order to use his guns effectively, the pilot's arcs of view had therefore to be made as large as possible. Though "looping" itself was little used, half-loops and "Immelmann" turns enabled the pilot to turn rapidly while gaining height.

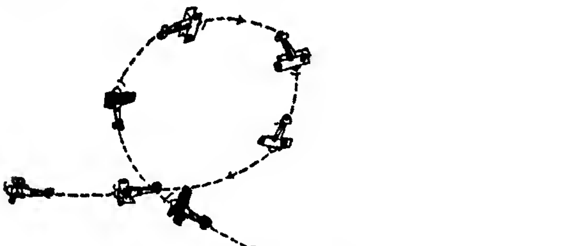

FIG. 5.—Immelmann Turn.

Until 1916 spinning nose-dives had merely been associated with loss of flying speed and control, almost always with fatal results. A courageous demonstration of the method of recovery from a spin by Goodden, and later the practical application of the theory by Lindemann, both at the Royal Aircraft factory, did much to prevent future accidents. A spin came to be regarded, not with fear, but as a means, if crippled, of eluding attack.

French pilots again pointed the way in the art of "rolling," a manoeuvre in which the aeroplane is rolled about its longitudinal axis. In 1917 this manoeuvre was widely practised. The development of an aerial combat was so swift that the first few seconds might decide the fate of one of the opponents. It was rather in a brilliant combination of the manoeuvres described above, calculated to make effective striking possible while presenting an elusive target, than in the use of any single manoeuvre, that the war pilot put his trust. He had to study the characteristics of the aeroplane he was attacking, single or two-seater or large bomber, gauge its weakness, divine the mentality of its pilot and pit his skill against it; but it was grit and the will to close and finish it that alone could be the decisive factor.

To make possible the achievements of the fighting pilots, and to solve aerodynamic problems continuous experiments with new engines were carried on behind the scenes. High performance and controllability were not achieved without the incessant labour of scientists and designers, who were not a little baffled by the conflicting and rapidly changing demands often expressed with emphasis rather than illuminating precision; by the time new features in design could be given air trial the original demand had changed out of recognition.

And for military requirements something more than controllability was required; for besides having to control the aeroplane the pilot had to examine maps, operate wireless, watch many instruments, navigate, care for his guns, and keep a perfect look-out. If the controls were temporarily released the aeroplane ought in some measure to look after itself; in other words, be stable. In 1914 the BE2, and later the FE2, aeroplanes were altered so as to be stable longitudinally in partial conformity with Busk's RE1 design. They were thereupon called BE2C and FE2B; with these the flier's hands were free, and with them no less than seven airships were brought down, a result no doubt assisted by the confidence which stability inspired in night flying. But it then seemed that stability impaired controllability. By 1916 so strongly did war pilots desire the maximum of control that for some time many looked upon stability with disfavour. Gradually, however, a neutral stability was found to be compatible with the desired control. An added safety was that stable aeroplanes would automatically tend to recover from a spin after loss of control, and that, unlike unstable aeroplanes, they would tend to return to a normal attitude if they became inverted unintentionally or during the course of violent manoeuvres. Great as was this advance in aerodynamic knowledge, problems equally great remain, the solution of which can only be reached by constant and arduous experiment.

The Return to Peace.—Civil aviation was mainly restarted by the conversion of war types, which were not so well suited as if designed for the purpose. Specialization of type commenced in two directions: aeroplanes destined for travel and transport and those designed for racing.

The year 1919 saw wonders as great as any that had gone before. On June 14th–15th Alcock crossed the Atlantic on a Vickers-Vimy with twin Rolls engines in 16 hours 12 minutes, by which he won the *Daily Mail* £10,000 prize, and for which he was knighted. Of Hawker's plucky attempt and descent into mid-Atlantic; of Alcock's battle with driving mist, cloud and darkness; of the navigation of Whitten Brown, his companion; above all, of the human endurance underlying the feat, it is impossible to speak in measured terms. Just prior to Alcock's achievement there was one of a different kind, a triumph of organization for the Americans; for Lt.-Comm. Read and his crew came from America to England *via* the Azores and Lisbon, including the remarkable passage of 150 m. under power on a rough sea, in the flying-boat NC4. In the late autumn Ross-Smith and his brother flew another Vickers-Vimy to Australia in 28 days, won the £10,000 offered by the Australian Government, and were both knighted.

High-powered racing aeroplanes again appeared. Janello, in an Italian seaplane, put up a fine performance for the Schneider Cup at Bournemouth at a speed estimated at 140 m.p.h., but, though virtual winner, had unfortunately to be disqualified. Gathergood won the Aerial Derby at 129 m.p.h. on a De Haviland aeroplane. Racing machines reached speeds of 170 and 180 m.p.h., and climbs were made to over 30,000 feet.

In 1920 Van Ryneveld flew from England to Cairo, and thence after many adventures to the Cape. He crashed two aeroplanes on the way, and arrived at his destination on a third supplied by the South African Government; but considering the conditions for flying in Central Africa his achievement is of the first rank.

The Schneider Cup and the Gordon Bennett, two classic races, were won respectively for Italy by Lt. Bologna in a Savoia seaplane at Venice with an average speed of 106 m.p.h., and by Sadi Lecointe at Étampes at 169 m. per hour. Courtney won the fifth Aerial Derby in a Martinsyde racer with an average speed of 153 m. per hour. At Étampes the Farman "Goliath," a large passenger machine, remained aloft for 24 hours 19 minutes, beating all duration records. In America Maj. Schroeder on a Le Père biplane with a supercharged engine reached a height of 33,000 feet. The fast American and French racers continually raised the speed record, until Sadi Lecointe on a Nieuport reached 313 km. per hour over a measured kilometre. By the end of 1920 racing machines had reached a speed of nearly 200 m.p.h., a military type scout had climbed to 20,000 ft. in 15 minutes, a large commercial machine had climbed to 15,000 ft. with a weight equivalent to 26 passengers, fliers had climbed over six miles into the air, and an aeroplane had remained aloft for over 24 hours.

To promote safety, experiments were carried out to reduce landing-speed while retaining a reasonable top speed by means of wings variable in flight, a problem to the solution of which Handley Page offered a notable contribution. In spite of these and other difficulties so little risk now remains that the number of miles flown for every accident is something like 35,000, or one-and-a-half times round the world.

The years from 1909 to 1920 reveal a story of progress that, even allowing for the extraordinary stimulus of the World War,

is surely without parallel in the annals of engineering. And in this story may be found the hint of a tremendous future.

II. Development of Aeroplane Design

Design of Lifting Surfaces.—The determination of the forces acting upon a body moving through a viscous fluid, such as the atmosphere, is a problem so far not amenable to mathematical solution, and design must therefore be based upon experiment. A vast mass of experimental data has been obtained by testing models in wind tunnels (by Eiffel in Paris, by Prandtl at Göttingen, at the National Physical and other laboratories) and by experiments upon aeroplanes in flight, principally in England at the Royal Aircraft Establishment, Farnborough. A very useful amount of information had been acquired before the war, but this has been greatly extended during the war period.

Lifting-surfaces of various shapes have been used in the design of aeroplanes, disposed in a variety of ways. It was immediately evident that the span or spread of the wing across the line of flight should be large in comparison with the "chord" or dimension along the flight path. The ratio of the span to the chord has been termed the "aspect ratio." Aerodynamic efficiency increases with increasing aspect ratio; but it is desirable to limit the aspect ratio for constructional reasons and in order to reduce the room required for housing. The greater aerodynamic efficiency, moreover, becomes neutralized after a point by the head resistance due to the additional external bracing required. A compromise must be made, and the average figure used is in the region of six to one. It was also evident that the wings should be cambered along the line of flight. The early aeroplane wings had approximately the same curvature of upper and lower surfaces. Wind-tunnel experiments, however, showed that the curvature of the under surface had but small influence compared with that of the upper surface, a result which enabled the designer to increase the thickness and internal strength of the wings and reduce external bracing.

Extensive wind-tunnel research has been carried out to find the best cross-section shape of wings. Greater lift can be obtained from highly cambered wings, but thinner wings offer less resistance to motion at small angles. An aeroplane should have as large a speed range as possible. While a wing of high lifting-capacity is required to fly slow, small resistance is required for fast flying, that is at fine angles of attack. A greater speed range is obtained by the use of wings of small curvature (about 1 in 15), the same lower limit being attained by the use of a larger area to carry a given weight. Wind-tunnel experiments further determined the extent to which the curvature should be greater towards the leading edge of the wing.

Early writers sometimes stated the requirements of a wing as consisting purely of a high ratio of lift to resistance at some angle of attack. The requirements are in reality more complex. To secure a wide range of speed a high ratio of lift to resistance is required at fine angles (fine in comparison with the angle at which the wing attains its greatest lift at a given speed) and in addition a high value of this ratio is required at the intermediate angle at which the aeroplane climbs. This is not all. For longitudinal stability the travel of the centre of pressure when the angle of attack varies should be small, as this travel on a curved surface produces instability. The wing section best meeting all these requirements is probably the British Royal Aircraft Factory's No. 15, designed early in 1916.

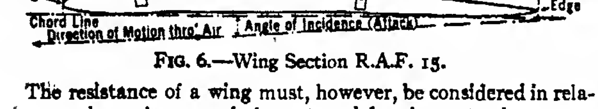

Fig. 6.—Wing Section R.A.F. 15.

The resistance of a wing must, however, be considered in relation to the resistance of the external bracing attendant upon its use. It has been suggested that the thick wing, in spite of greater head resistance due to the wing, might prove superior by making possible the suppression of all external bracing, and

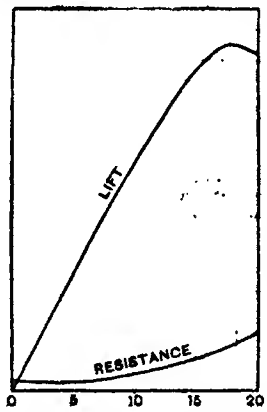

Fig. 6a.—Variation of the Lift and Resistance of a wing with Angle of Attack.

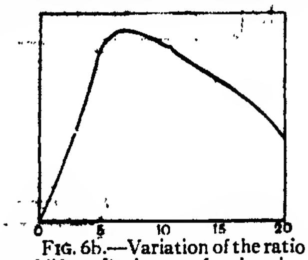

Fig. 6b.—Variation of the ratio of lift to Resistance for the wing alone as the Angle varies.

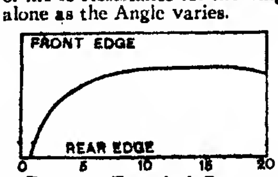

Fig. 6c.—Travel of Centre of Pressure as Angle of Attack varies.

the German Junker and others have designed aeroplanes on these lines.

The term "wing" is commonly used of the half of a lifting-surface on one side of the aeroplane, the whole surface constituting a "plane." Thus a monoplane has one pair of wings. A tandem aeroplane has two or more pairs of wings arranged as the name implies. The terms "biplane," "triplane," "quadruplane" denote that two, three, or four planes are superposed. Langley's "aerodrome" is an early example of the tandem aeroplane. This type is inconvenient structurally and aerodynamically very inefficient. The rear plane acts upon air to which a downward trend has been imparted by the plane in front. The reaction upon the rear plane is therefore inclined backward by the angle through which the air has been "downwashed" by the leading plane. In multiplane systems in which the planes are placed one above the other, each plane operates in air whose motion is influenced by the others, and the ratio of resistance to lift is less than the ratio which each would experience if acting alone. If, however, the planes are placed at a sufficient distance apart, so that the gap between is roughly equal to the chord of the planes, the mutual interference produces an effect comparable with that due to a reduction in aspect ratio such as is found necessary in the design of a monoplane. Using the same aspect ratio a given area is disposed in a biplane in half the span required in a monoplane. The biplane forms a good structure, the planes forming the flanges of a box girder. In the monoplane the bracing wires make small angles with the planes, with consequent high tension in the wires and high compression in the spars of the wing. In the biplane the wires make obtuser angles with the planes. In reviewing the examples of the two types, it is found that the monoplanes are relatively of heavy wing loading and low aspect ratio. In the triplane the upper and lower planes may form the flanges of the girder, or the structure may consist of two girders superposed. This does not possess the same structural superiority over the biplane, as does the latter over the monoplane. The triplane arrangement provides a means of reducing span by increasing height. An early example of the triplane is that designed and flown by A. V. Roe in 1909. A Sopwith triplane was used by the British army during the war. The type may be suitable to large aeroplanes, in which reduction of the weight of the structure and of bulk is especially needed.

The great majority of aeroplanes have been of the monoplane and the biplane types, the latter predominating since 1912. The first aeroplanes to fly were biplanes and by far the larger number of aeroplanes in use to-day are of this type. The monoplane appeared about the opening date of the period under

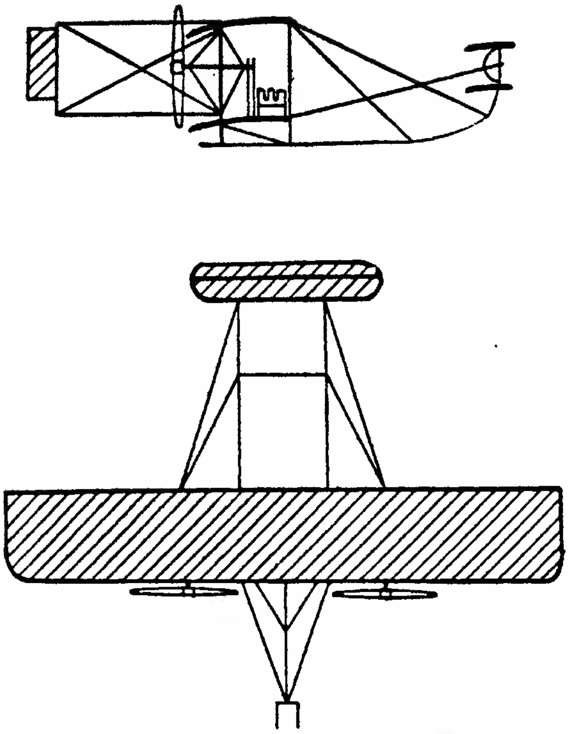

FIG. 7.—Early Wright Aeroplane. (Propeller Biplane.) (Elevators in Front; Rudder in Rear.)

discussion, and on an aeroplane of this type Blériot crossed the Channel in July 1909. It was more cleanly designed than the biplane of that date and was regarded as the faster type. It was largely used for trick flying, and figured ever more widely in aeronautical exhibitions. At the outset of the war it had still a reputation for speed, but had found a rival in the better de-

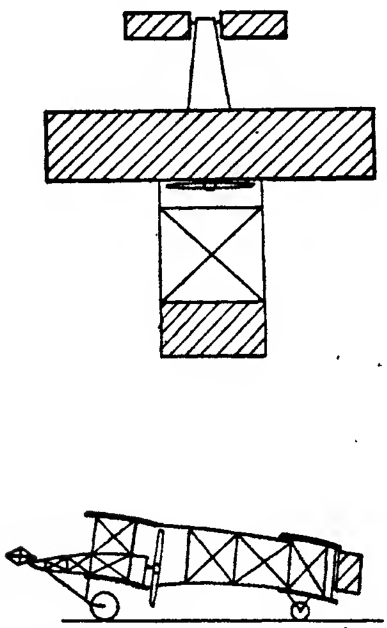

FIG. 7a.—Early Farman Aeroplane. (Propeller Biplane.) (Elevator in Front; Rudder in Rear.)

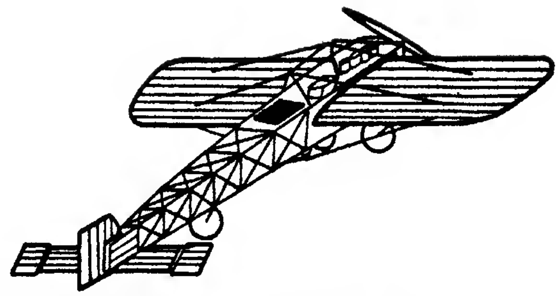

FIG. 7b.—Early Blériot Aeroplane. (Tractor Monoplane.) (Elevators and Rudder in Rear.)

signed "tractor" biplanes. During the war the monoplane was more largely used by the French and the Germans than by the British. The names most associated with the monoplane are French: Blériot, Morane, Nieuport. The "Fokker" monoplanes used by the Germans take their name from a Dutch designer probably inspired by the French designs. During the years 1914–8, the biplane was in the ascendant, but the monoplane was afterwards revived in the form of the aeroplane with thick "cantilever" wings without external bracing. The monoplane appears to be a type convenient in small sizes, but unsuited for the larger aeroplanes.

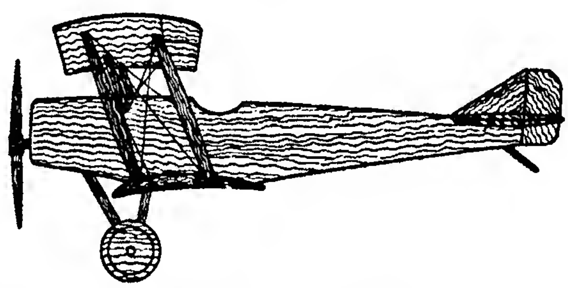

FIG. 8.—Modern Tractor Biplane.

Position of the Airscrew.—Airscrews have been described as "tractor" or "propeller" according as the airscrew shaft is placed in tension or in compression by the thrust, and corresponding aeroplanes are usually called by the same names. The first biplanes, those of the Wrights and the Farmans, were of the "propeller" type, colloquially "pushers"; almost all monoplanes were "tractors."

In the tractor, monoplane or biplane, the order of disposition of the component parts is generally from front to rear:—airscrew, engine, crew; and the body is prolonged to carry stabilizing and controlling surfaces at the rear. In the pusher the order is reversed and the controlling surfaces are carried on an open frame ("outriggers") in front, at the rear, or in both positions.

On a "pusher" the field of view forward is superior, and great stress was laid upon this by the British War Office after the military trials in 1912. The necessity of aerial fighting was proved in 1914, and the tractor was found unsuitable owing to the obstruction in the most effective direction for firing. Pushers were therefore ordered for fighting, at first carrying pilot and gunner, and later carrying only one man with a machine-gun fixed in the aeroplane. The situation was completely altered by the device of firing through the airscrew disc. The blades were at first protected by deflector plates, but shortly after mechanism was used to time the fire between them, the invention of Constantinescu, a Rumanian. The aeroplane was directed bodily at the target. The "tractor" then replaced the "pusher" fighting aeroplane; but "propeller" airscrews continued to be used on seaplanes, on aeroplanes for night duty against Zeppelins, and on large twin-engine aeroplanes.

The " tractor " is the more convenient design, slightly better aerodynamically and reputed safer in a " crash."

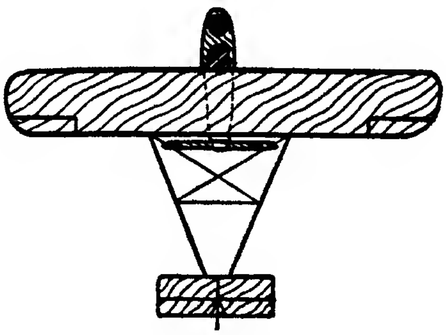

FIG. 9.—Propeller Biplane of 1914–16.

Weight and Head Resistance.—The aeroplane designer is continually interested in the relative importance of weight and head resistance. At the start attention was naturally concentrated upon the production of a light structure. Knowledge of the resistance to motion of bodies of various shapes was meagre and was most probably gauged in the mind of the designer by the frontal area exposed, irrespective of shape. It was not realized that a strut of circular section offers twelve times the resistance of a strut of the best " streamline " or " fair " shape of the same frontal area. The light biplane structure of the Wrights and the Farmans contained a network of struts and wires offering a very high resistance. To reduce resistance, exposed parts may be " faired," which involves adding weight; and the number of external parts may be reduced, which again increases the weight of the structure. Wrights and Farmans may be contrasted with the fast monoplanes and biplanes, the latter employing only a single bay of struts on either side, and finally with the unbraced monoplanes of Junker and Fokker.

" Streamline " wires were first designed for the British army dirigible " Beta " in 1912, and fairshaped wires were in 1914 fitted to aeroplanes designed at the Royal Aircraft Factory. They have since become the most usual bracing of British aeroplanes. They offer approximately one-eighth of the resistance of cable of the same tensile strength. Their metallurgy required careful study, and hence in other countries cable has continued to be used, frequently duplicated, the cables lying one behind the other with a wood " fairing " between them. Struts of streamline shape were in use at an earlier date. The bodies of aeroplanes have improved in form, the crew has been protected from wind pressure, and the spokes of wheels have been covered in with fabric.

The drag of a biplane of moderate speed is made up roughly as follows:—

Main planes	30%
Bracing of main planes	20%
Body	30%
Undercarriage	15%
Tail surfaces	5%

These figures show the importance of careful design of all parts. Much of the resistance of the wing-bracing occurs at the joints of wires and struts to the planes, and the resistance of the body is largely due to the necessity of cooling the engine, either by water radiator or by flow of air over the cylinders.

The weight of the complete structure, excluding the power unit, fuel, crew and other load borne, is about one-third of the whole weight of the aeroplane, but varies with the total weight, with the weight carried per unit of area of lifting surface, and with the strength of the structure. The following figures are averages for a number of British aeroplanes:—

Total weight	2,000 lb.				10,000 lb.			
Area of lifting surface	335 sq. ft.		200 sq. ft.		1,700 sq. ft.		1,000 sq. ft.	
Load borne per unit area	6		10		6		10	
Load factor	4	8	4	8	4	8	4	8
Structure weight of % of total weight	28 %	35 %	27 %	34 %	31 %	40 %	29 %	37 %

The " load factor " is the number of times the weight of the craft which the wings will support; a measure of the strength.

Using one of the light engines now available, the power unit to give a speed of 100 m. an hour will weigh about one-quarter of the total, leaving 40 to 45% for fuel, crew and cargo.

Wing Loading and Horse-Power.—The lift of a wing is proportional to its surface, the atmospheric density, the square of the speed and the angle at which it meets the air measured from the angle giving no lift and up to an angle near that known as the " critical angle." At this angle the lift is a maximum (if the other factors be supposed constant) and above it the lift decreases. The wing in passing through this angle is said to be " stalled." Stalling occurs when flying as slowly as possible. After stalling it is no longer possible to increase the lift by depressing the tail of the aeroplane and it is necessary to dive in order to recover flying speed. This has been a frequent cause of accidents when flying too low to have room for a dive. Moreover, the wings when stalled have lost their normal tendency to oppose rotation about the line of flight and now tend to " auto-rotate " or act as a windmill. The aeroplane may therefore drop one wing and pass into a steep spiral glide known as a " spinning nose-dive " from which it may be brought to normal flight by the same diving process reducing the angle of attack of the wings. There is no danger in the stall or the spin so long as there is space for the recovery and knowledge of the action required.

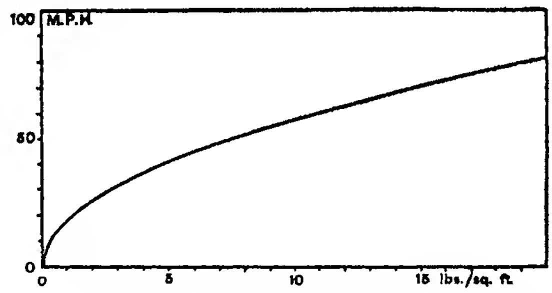

FIG. 10.—Curve showing lowest speed of flight possible with given wing-loading and the usual thin wings.

Wing-loading, the weight borne per unit area of sustaining surface, determines the speed at which the wings become stalled and therefore the slowest alighting speed. With constant loading, as the speed of aeroplanes increases, wings attack the air at ever finer angles, very soon passing the angle of lowest resistance for a given lift. To increase speed it therefore becomes desirable to increase the loading, or in other words to reduce the area of the wings. This reduction has also the merit that it reduces the bulk of the craft, the resistance of external bracing and the weight of the wing structure. To attain the greatest height heavy wing-loading is not required, and the best loading for a high ceiling would to-day be considered a light loading. For fighting, power of rapid manoeuvre is essential. The aeroplane of light loading can be turned in a smaller circle. The total weight is, however, approximately fixed by military considerations, and light loading implies large wing area and consequent greater resistance to angular acceleration, so that the lightly loaded aeroplane cannot so quickly be " banked " to the correct angle for the turn. Given the wing area, the aeroplane having the lighter loading is the more manoeuvrable; given the weight, the heavier loaded aeroplane is at least the equal of the other. Aeroplanes carry a larger area of sustaining surface than they require, except for alighting, and it is the

difficulty of bringing the aeroplane to land at high speeds which prevents the increase of loading beyond 10 lb. to the square foot.

In commercial use, economy dictates an increase of loading; safety demands that the aeroplane may alight at speeds and in a space impossible with high loading. Attempts have been made to make the wing area or the wing shape variable in order to reduce the lowest speed of flight, while retaining the other advantages of heavy loading. None has so far been successful.

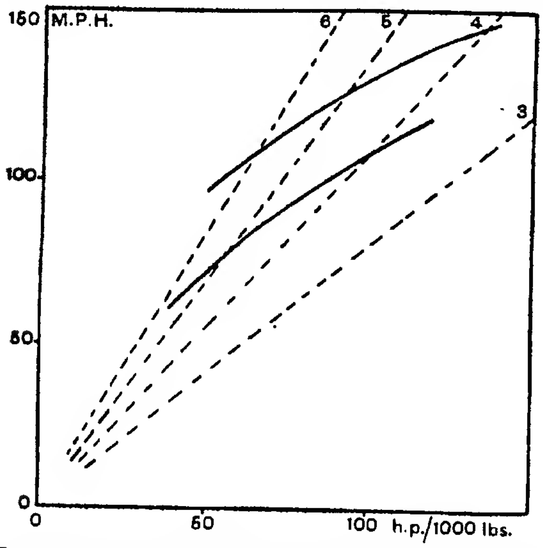

FIG. 11.—Diagram showing speeds attained by British aeroplanes at a height of 10,000 feet. The speeds vary between the upper and lower curves. The base is engine power at ground level per 1,000 pounds of total weight. The dotted lines are lines of constant ratio of tractive force to weight, marked with the values of this ratio.

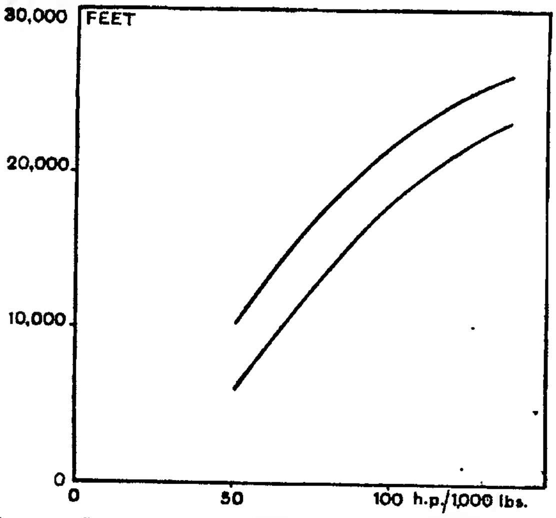

FIG. 12.—Diagram showing greatest effective height attainable by British military aeroplanes. These vary between the upper and lower curves. The base is engine power at ground level per 1,000 pounds of total weight.

During the period 1909 to 1921 the speed attained by aeroplanes was more than doubled. The rate of climb and the height attainable have increased in a larger ratio. Greater knowledge and better design have improved the aerodynamic efficiency of the aeroplane; but the improvement of performance is in the main due to the use of larger engines. In 1918 four times the power was being used that was used in 1914 for the same purpose—the reconnaissance two-seater aeroplane—and the speed is more than half as great again. Aerodynamically there is little difference between the two aeroplanes. As the power of engines grew their weight per horse-power was reduced. To save two pounds in every four on an engine weighing one-third of the whole aeroplane was important.

The largest engines developed were insufficient for the larger aeroplanes, into which two engines were commonly built, and in some cases four or more.

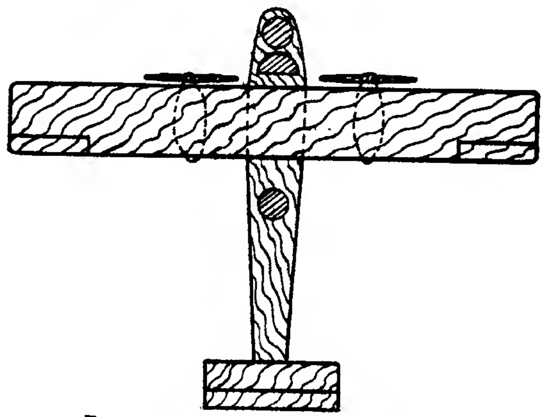

FIG. 13.—Large Twin-Engine Aeroplane.

Two separate power units have been regarded as conducive to safety. Experience has so far not confirmed this. It is essential that the power of one engine alone should be sufficient to fly the aeroplane, and the "twin-engine" aeroplanes used during the war were not all provided with so large a total power. Again, the engines were carried on either side of the centre and the line of thrust of each offset by a considerable amount. This introduced difficulties of control, because rudders were unable to balance the offset line of thrust at the low speed at which the aeroplane could be flown level on one engine only, and there was danger in the event of sudden failure of one engine near the ground.

The table gives some particulars of a few typical aeroplanes through the period under review. The figures are approximate:—

Name	Date	Flying weight lb.	Lifting surface sq. ft.	Horse power	Wing load lb. per sq. ft.	H.P. per 1000 lb.	Speed, m.p.h.
Wright	1908	1,000	540	25	1·8	25	40
Farman	1908	1,150	560	40	2·1	35	30–40
Blériot	1909	670	168	25	4	40	
Roe triplane	1909	400	320	10	1·25	25	
Dunne	1910	1,700	560	50	3	30	40
Cody	1911	1,400	690	50	2	35	40
Roe biplane	1911	750	280	30	2·7	40	40
	The horse-power and speed given above are uncertain.						
Aeroplanes in British War Office trials 1912		1,500 to 2,150		45 to 120	2·9 to 9·5	35 to 55	Up to 75
BE2C	1914–5	2,140	370	100	5·8	46	80
Bristol Fighter	1916–7	2,800	400	250	7	90	115
SE5a	1916–7	2,000	250	210	8	100	130
Sopwith Camel	1916–7	1,480	230	125	6·4	85	110
Handley Page 0/400	1916–7	14,000	1,640	550	8·5	40	80
De Haviland 9A	1918–9	4,220	490	400	8·5	95	125
Martinsyde F4	1918–9	2,290	330	300	7	130	145
De Haviland 10A	1918–9	9,000	850	810	10·5	90	120
Handley Page V/1500	1918–9	24,100	2,900	1,440	8·3	60	90

The Large Aeroplane.—For the same aerodynamic performance, the lifting-surface of an aeroplane must be propor-

tional to the weight. If aeroplanes of all sizes were constructed of the same materials and geometrically similar in all parts, the weight of the structure would increase with increasing size as the cube of the linear dimensions, that is, as the 3/2 power of the total weight. This does not in fact obtain, because geometric similarity would give greater strength to the larger aeroplane; also the design may be elaborated and materials worked to relatively finer dimensions; and moreover, large aeroplanes are not designed to have the same strength as smaller craft, as they are less sharply manoeuvred. Nevertheless, the weight of the structure is to be expected and is in fact found to become a larger proportion of the total weight as the size increases. It is therefore disadvantageous to increase size indefinitely and there is in fact a best size depending upon the duty to be done.

To carry an indivisible unit of cargo, such as a large bomb, an aeroplane of at least a certain size is required; hence we find size increasing. Sometimes it is preferable to carry a total load in a smaller number of larger aeroplanes, because the weight of the crew becomes less in proportion to the cargo carried, so that every square foot of wing and every unit of engine power of a fleet carries more useful load. Initial outlay and fuel consumption are reduced and there is further an economy of pilots. At some point the larger aeroplane requires a larger crew, and for war the larger "bomber" must carry a number of gunners and offensive armament for defence against more mobile attackers. The optimum size for a commercial service with a sufficient volume of traffic is what would be termed to-day a large aeroplane (say 7,000 lb. at least). The actual size depends to some extent upon the speed of the service, which governs the relative costs of fuel and personnel, and also upon the distances.

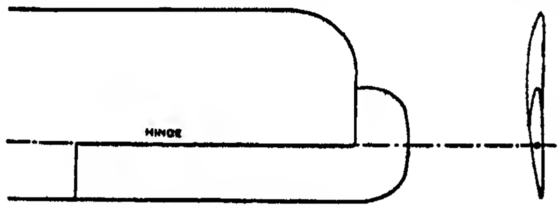
The first large aeroplane flown was the Russian Sykorsky in 1913. Large aeroplanes were demanded in 1915 for bombing and were increasingly used during the war. The Handley Page (13,000 lb. gross) was extensively used by the British. The "Gotha" and others were used for raids on London. The same Handley Page aeroplanes and a subsequent design were employed on a passenger service between London and Paris throughout 1919 and 1920. The "Vimy" (12,500 lb. gross) crossed the Atlantic, flew from Cairo to the Cape, and from Europe to Australia, and has been used on a London-Paris commercial service.

Controlling Surfaces.—Stability in aviation is discussed in Section III. Complete inherent stability is obtainable by a proper distribution of weight and subsidiary surfaces and suitable arrangement of the main planes. The planes are commonly inclined upwards from root to tip to secure a righting couple if one wing tip falls and the aeroplane begins to sideslip. A vertical surface at the rear, known as a fin, is general although the rudder may entirely replace this surface. The travel of the "centre of lift" of the wings is such as to produce instability, and a subsidiary horizontal surface is required either in front or in the rear. To secure "longitudinal" stability, the centre of gravity must be sufficiently forward in relation to the main planes, and the load on the subsidiary surface maintains equilibrium. The aeroplane has three degrees of angular freedom and has almost invariably employed three means of control: elevators, to produce a "pitching" motion, and so govern the angle of attack of the wings and the speed of flight; rudders to produce motion about the vertical axis; and warp or ailerons, to secure lateral balance and adjust the angle of "bank." The early Voisin aeroplanes had no control for lateral balance. The aeroplane when turning has a natural tendency to bank, which is accentuated or reduced by sideslip outwards and inwards respectively if the wings are inclined upwards from root to tip or fitted with a vertical surface above the centre of gravity. The Voisin aeroplane carried curtains between the planes to provide this righting couple and was sufficiently controllable for the requirements of the pioneer content to achieve flight. "Lateral" control is desirable and is clearly necessary for rapid manoeuvring. The Wrights obtained this by twisting or "warping" the wings, and this method was extensively used up to the end of 1914. Control has been more generally obtained by means of hinged portions of the wings at the rear near the wing tips.

Elevators have been placed both in front and in the rear: rudders always in the rear. They have constituted the whole, or only a part of, the necessary stabilizing surfaces. Control with a single rudder requires an effective "keel" surface, which is adequately provided by the body of the aeroplane and the exposed struts of the structure. The tendency of design towards the "tractor" type places elevators and rudders most conveniently at the rear end, and this gives a clear field of view forwards. The early biplanes with an elevator in front and rudder at the rear disappeared about 1914; the monoplanes conformed to the modern usage. Both elevators and rudders are usually hinged portions of fixed surfaces, but in some cases the entire surface has been movable and constituted the elevator or rudder. The latter arrangement has not provided stability if the controls were abandoned. Later the fixed horizontal surface was made adjustable by the pilot during flight and known as a "trimming tail plane," a device much used by the British from 1916 onwards. It enabled the flier to vary the speed of flight at which no pressure upon the controlling lever was required, and effectively increased the range of control resulting from the application of a definite force.

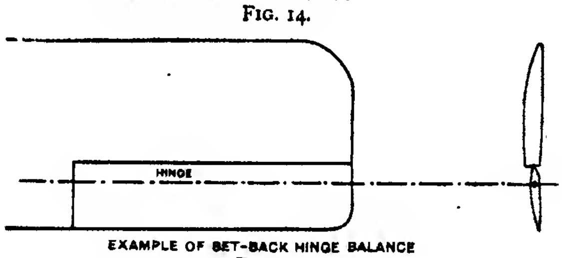
The arrangement of control levers or wheels, at first very diverse, became standardized in 1915–6, and consists of a "rudder bar" operated by the feet and a hand lever whose fore-and-aft movement operates the elevators and whose lateral movement provides lateral control. The rudder bar and the lever are moved in the direction in which it is desired to move the aeroplane. In larger aeroplanes rotation of a wheel mounted on the fore-and-aft lever actuates the ailerons, the fore-and-aft control remaining as before. The lever or wheel is generally connected to the control surfaces by steel cables, although shafts in torsion and tension or compression members have also been used.

Balanced control surfaces, although in use from an early date, only became necessary as the size of aeroplanes increased. A part of the surface to be balanced is carried in front of the hinge and this surface is most frequently the rear portion of a fixed element, the part brought forward of the hinge being extended beyond the end of the fixed element. This so-called "horn" balance proved unsatisfactory. If a large "horn" were used (adequate to give ease in normal flight), there was overbalance at low speeds, or when the aeroplane sideslipped, and the controls would then tend to "take charge." A more uniform effort results if the balancing projection is run the full span of the hinge, which must then be set back behind the fixed element. The front edge of the balanced surface is sharp and its movement takes place behind the bluff end of the fixed element. Alternatively separate balancing surfaces in advance of the hinge have been rigidly attached to the moving element and placed above the fixed element.



EXAMPLE OF HORN BALANCE

FIG. 14.



EXAMPLE OF SET-BACK HINGE BALANCE

FIG. 14a.

Two Methods of Balancing Ailerons.

The imperfection of balancing obtained has led to the development of relay motors to reduce the effort. In these, power derived from the air by a small windmill is brought into play whenever the flier attempts to move the controls. Relay motors had been but little used up to 1921.

Chassis or Undercarriage.—The Wright aeroplane alighted upon skids. It was launched by a catapult. The French pioneers took the air under their own power, and the Farman and Blériot used wheels. From 1909–14 combined wheels and skids were used. The wheels were commonly sprung by means of rubber cord. The skids might be brought into action if the alighting were imperfectly executed, and were carried well forward to prevent the aeroplane from turning over forwards when landing. Sometimes additional wheels were fitted in a forward position in place of the skids for this purpose. Under the tail a wheel was often fitted, but a small skid was used alternatively. Wing-tip wheels or more commonly light skids were used to protect the wing tips from contact with the ground. In Blériot's

undercarriage the wheels were mounted as castors to facilitate landing across the wind. This was subsequently abandoned.

The common arrangement of undercarriage comprises a pair of wheels a little forward of the centre of gravity of the aeroplane and a small tail skid. The wheels, of wire-spoke construction with pneumatic tires, are carried on an axle of steel tube attached to two V-struts from the aeroplane by rubber cord. The tail skid is also sprung by means of rubber and is mounted on a swivel. Steering on the ground was improved in 1912 by arranging the tail skid to be moved by the rudder bar. The use of skids and wheels ahead of the main wheels was generally abandoned early in the war, except in the case of large aeroplanes.

Steel springs have been used, but rubber is superior to steel because it stores more energy for a given weight. Hysteresis in rubber is also much greater than in steel. To avoid bouncing after the first shock the energy received on impact should be restored as little as possible. This requirement led to the design of undercarriages containing a combination of steel spring and oil dashpot, such as the "Oleo" design fitted to the Breguet and to the Royal Aircraft Factory's "BE2" in 1914. This form of "shock absorber" was chiefly useful for night flying.

Methods of Construction.—The first experimenters built their aeroplanes of wood and fabric with metal at joints and in the form of piano-wire bracing. The aeroplane of to-day uses spruce for beams and struts and steel for joints and tension members, the latter in the form of stranded cable, or "rafwires," *i.e.* rods rolled to a "streamline" section. Wings and body are covered with linen, pulled taut by "dope," and varnished or painted for protection from sunlight and moisture. Frames composed entirely of metal were used as early as 1911, but wood remains in general use, except for the tropics. Steel tubes have been extensively used in parts, notably for the part of the body to which the engine is attached, for struts between the planes, and in the undercarriage. The use of steel tubes for the engine-bearers gave place to wood owing to the greater absorption of vibration obtained.

The wings in the common type of biplane contain two wood spars of I or box section forming the flanges of a truss braced by wood or steel struts and cables or solid wires. To these spars are attached transverse ribs which give the shape of the wing and a light wood edge completes the frame. The linen covering is sewn on to this with a seam along the rear edge; stitched to every rib since 1914. The body is most often a frame of wood compression members and wire bracing. Bodies built of three-ply wood, with or without reinforcing members, have also been used. These retain their shape better and, being infinitely redundant structures, have perhaps some advantage against rifle fire; but the former have been preferred apparently as being more easily repaired and inspected and allowing of a more certain calculation of stresses.

Metal construction advanced further in Germany than in other countries. Junker produced aeroplanes without external bracing, strength being obtained by the use of thick wings. These contained in place of the usual two spars a number of steel tubes interconnected by tubes forming triangles. The wings were covered with aluminium sheet corrugated so that the air flowed along the corrugations. The interconnecting tubes and the corrugations replaced the usual ribs. Great Britain has experimented with spars and ribs of steel and duralumin, and secured the necessary strength without increase of weight; but metal construction is still in the experimental stage. The principal difficulty in the use of steel lies in the prevention of local buckling due to the thin gauge of metal required to secure a light structure. Welding is unreliable owing to the impossibility of detecting weakness in the finished part, and joints are made by rivets or bolts. Bodies have been made of duralumin on the same lines as those built of three-ply wood.

The Strength Required in the Structure.—The aeroplane structure is subjected to a very variable load. In straight flight the wings support the weight of the craft. A sudden gust, or change in the direction, or speed of the relative wind, momentarily increases or decreases the load. To estimate the extent of this, the proportion which any possible gust bears to the speed of flight must be known. On a banked turn or when returning to level flight after diving, the wings must provide an accelerating force, depending upon the rate of turn and the speed of flight. The pioneers were content to fly warily, and the accelerations necessary when they turned were small. The larger variations in loads were due to gusts. They flew only in the calmest weather, but their speed was slow. As soon as the aeroplane was used for trick flying, the effect of gusts became relatively insignificant, and the accelerations due to manoeuvres became the necessary basis of design. In an aerial combat the wings may have to sustain over three times the normal load, and it is not practicable to design a fighting aeroplane for the accelerations which could be produced by flattening out too rapidly from a steep dive, in which a speed of over 200 m. an hour may be reached.

The determination of the load variation possible is one part of the problem of specifying the strength required of the wing structure. We must also know how this load is distributed over the surface, along and across the wing, and how it is shared by the different members of the structure. The important factor is the variation of the "centre of pressure" on the wing. As the angle between the wing and the direction of motion decreases the centre of pressure moves backward with increasing rapidity. It may be noted here that in a nearly vertical dive at high speed, although the lift of the wings is small, there is a large couple acting upon them tending to twist them and to turn the aeroplane over on its back; this is resisted by the action of the tail. A number of the early accidents occurred in the course of a "*vol piqué*," or steep dive.

Rough calculations were probably made of the strength of the early aeroplanes, and in 1911–2 those supplied to the Government were tested by inverting them and loading the wings with sand. Spars of wings were also tested separately, but as a rule both the strength required and the strength realized were uncertain quantities. A number of accidents to monoplanes led to this type becoming suspect. Early in 1912 Blériot forwarded a suggested explanation to the French War Office, which resulted in the suspension for a few months of the use of monoplanes by the French army. Later in the year accidents to monoplanes in England led to a suspension of their use by the War Office, although the navy continued to use them. A committee was appointed and reported early in 1913. It decided that the accidents were due to the construction of these monoplanes, but not to anything inherent in the monoplane system. They recommended that the wings should be braced internally against drag (a remarkable omission previously), the main bracing wires duplicated and made independent of the undercarriage, and the fabric well fastened to the ribs, especially on the upper surface. Makers were to supply evidence of strength; official inspection and investigation of accidents were instituted; and the question of stability and the danger of the "*vol piqué*" and recovery were to be investigated.

Prior to this, efforts had been made in England to impose a factor of strength based on the load in straight level flight through steady air. The same factor has since been termed the "load factor." In 1914 the British Advisory Committee for Aeronautics issued a report on "factors of safety," regarding the load factor as the product of two factors, one representing the number of times maximum load might exceed the normal load, and the other a factor to cover possible faults of material and workmanship. The first factor is based on the acceleration due to a banked turn combined with a gust, and to recovery from a dive. Forty-five degrees was the steepest angle of bank considered advisable and it is recommended that to secure safety aeroplanes should not be dived to a speed exceeding the normal by more than 20 per cent. The committee advised that the structure should have a factor of safety of at least 2 under the acceleration so obtained. A factor of from 6 to 8 (which had been worked to by the Royal Aircraft Factory since 1912) was recommended, to be increased to 12 if this should become possible. There is no record of the obligatory use of such factors in France or Germany at this date.

During the war the problems involved were investigated both mathematically and by experiment. Loops and mock fights were carried out at the Royal Aircraft Factory by aeroplanes fitted with an accelerometer and with tension meters on the wires. The distribution of pressure over wings has been measured in wind tunnels (first by Eiffel in Paris) and on aeroplanes in flight at Farnborough. It is now possible to specify the strength of the various members of an aeroplane with sufficient accuracy for any manoeuvres required. The "load factor" demanded has never risen to 12, but now ranges from 4 to 8, the lower factor for the large aeroplane which is not so violently manoeuvred. The adequacy of these factors has been confirmed by experience.

The need for extreme lightness precludes the use of the factors of safety currently used in other branches of engineering, and instead accuracy of stress calculation and careful inspection and testing of materials are imposed. It became the practice of the British Government to check by its own officials the strength of each design by detail calculations of stresses and by a proof load on one aeroplane of a type. Other governments followed. Since 1918–9 Great Britain requires that an "air-worthiness certificate" be obtained before a type may be used for commercial purposes. Drawings are submitted by the applicant from which calculations of stresses are made by the Air Ministry.

The calculation of stresses proceeds upon the usual lines, common to other branches of engineering, but with rather greater accuracy of detail. The theorem of Three Moments is applied to the spars, which require treatment as beams continuous through a number of supports and subjected to end load. Aeronautical practice has somewhat extended this theorem. A theory of the strength of struts of tapering section has been evolved. Knowledge of the mechanical properties of timber has been much extended.

The Airscrew.—The Rankine-Froude theorems on propulsion by the sternward projection of a stream of the surrounding fluid by the use of a screw-propeller, or other means, are well known. These state that the highest efficiency is attained by the projection of the greatest amount of fluid at the lowest speed, and indicate the use of propellers of the greatest practicable diameter. The only waste considered is the kinetic energy imparted to the fluid. An upper limit of efficiency is thus determined in terms of the diameter and the thrust of the propeller and the speed of motion. The design of marine screws proceeds mainly upon empirical lines based upon experience. The early airscrews were designed by a similar process of trial and error.

F. W. Lanchester (*Aerodynamics*, 1892), regarding the airscrew blade as a twisted aeroplane wing rotating about one tip as it advances through the air, assumed that the total reaction may be obtained by integrating the forces which would act upon elements at successive radii if these were elements of a complete wing. This method of treatment, which was also advanced by Drzewiecki, has provided the basis of airscrew design. As first applied, the theory was incomplete, chiefly because it ignored the fact that the blades in following each other act on disturbed air. For example, if the number of blades be increased, the theory indicates no fall in the efficiency, and reactions directly proportional to the number of blades, which experiment showed to be untrue. Moreover, the efficiency so calculated might exceed that given by the Rankine-Froude theorems. It was therefore sought to combine the two aspects of the action of the airscrew in one theory, and the further theorem of Froude that the stream has reached half the final velocity at the propeller disc appeared to provide a means of estimating the degree of disturbance of the air in which the blade acts. It is generally agreed that the original theory is over-corrected by this modification. The blade element under consideration is itself partly causing the acceleration of the stream, and this acceleration is the total and not merely the initial disturbance of flow in the neighbourhood of the element. Figures for the reaction on the elements were obtained by testing a small wing of the same section in a wind produced artificially in a "wind tunnel." This wing produces a disturbance of flow equivalent in an airscrew to an acceleration.

It was found in practice that the assumption of an arbitrary acceleration less than one-half of the final acceleration made it possible by the use of the theory of Lanchester to predict the aerodynamic performance of an airscrew with a valuable accuracy. The combined theory leads to two important conclusions, completely verified by experience. Firstly, the efficiency increases with increasing ratio of the pitch at which the screw operates to its diameter up to an optimum value seldom employed in practice. Secondly, for given thrust and speed the diameter must be so large that it acts upon a sufficient mass of air per unit of time to attain a satisfactory efficiency. The latter brings the theory into conformity with the law of Rankine and Froude. The former in practice brings the airscrew designer into conflict with the designer of aeroplane motors. Higher crankshaft speeds are required to produce a light-weight internal-combustion engine than are demanded by this condition for high airscrew efficiency. This has resulted in a large number of aeroplane engines being arranged to drive the airscrew through a reduction gear. The point at which gearing becomes desirable in practice is not easily determined. It depends upon a number of factors. Among these are a small loss of energy in the gears, added weight and cost, various practical reasons for dispensing with additional mechanism if this is not of sufficient value and the adverse effects of the greater torque of the slower running airscrew upon the control of the aeroplane, which must be offset against the gain in airscrew efficiency. In this question is also involved the consideration of the strength of the airscrew to resist the stresses due to rotation. This imposes a limit upon diameter, decreasing as the speed of rotation is increased, which may result in a further reduction of efficiency for the high-speed airscrew.

During the war large aeroplanes were built for which single engines of the required power were not available. In so far as two engines were sufficient, these were placed on either side of the main body of the aeroplane, each driving a separate airscrew. It became necessary ultimately to install four engines in a few aeroplanes and these were placed in pairs driving two pairs of airscrews in tandem. The design of the rear propeller in this arrangement involves an estimate of the rate at which air is supplied to it by the screw in front. With the same limitation of diameter the efficiency of propulsion attainable is approximately the same as if the two engines were coupled and drove a single airscrew of the same diameter, but is less than would be obtained by the use of four separate systems of propulsion. The tandem system is preferred for reasons of compactness and the difficulties of control attendant upon the use of a number of lines of thrust.

The aeroplane propeller, unlike the propeller of ship or airship, is required to transmit the full power of the engine at different speeds of flight, both when the craft is flying level at full speed, and when it is flying slow in order to climb. The airscrew cannot be designed to discharge both functions in the most efficient manner possible in each case. This was of little consequence in the early days of flight when the range of flying speed was small; but as the range was increased, some attention was paid to the design of airscrews of variable pitch. These have been experimented with, notably at the Royal Aircraft Establishment, with some success; but they have not been used so far in service. If any device for preventing the loss of engine power with increasing height by an initial compression of the charge to ground-level density should come into use, the variable airscrew would become necessary. Such devices are, however, still in an experimental stage.

The number of blades in an airscrew is commonly two, but four blades have been extensively used. The two-bladed airscrew has an advantage in convenience for storing and transport. The use of more blades reduces vibration due to errors in blade angles, and eliminates gyroscopic vibration when the aeroplane is turning, and vibration due to aerodynamic causes both when the axis of rotation is inclined to the line of flight and when the aeroplane is turning. Airscrews have been almost universally made of timber, which should be continuous through the boss from blade tip to blade tip. This has prevented the use of three blades. In deciding the number of blades, two or four, the designer is largely guided by the blade area required, which depends upon the speed of motion of the blade and the power transmitted. Thus a slow-running airscrew has conveniently four blades, whereas for a high-speed screw two blades are preferred. A four-bladed high-speed screw might require such narrow blades that in order to resist the bending due to the thrust they would be so thick as to reduce the efficiency seriously.

At the speed of flight of an aeroplane the changes of pressure of the air flowing past the wings amount only to a small fraction of the atmospheric pressure. The blade tips of airscrews, however, commonly reach speeds of 800 ft. per second, approaching the velocity of sound in air. It follows that while the wings may be regarded as operating in a fluid of constant density, the compressibility of the air may have important effects in the case of the airscrew. With increase of blade speed effects must be anticipated similar to the phenomenon of cavitation experienced with marine screws. Such effects in a gas may, however, occur gradually with increasing speed. Experiments with small model wings in a wind tunnel in America showed a fall in lift and increase in resistance at speeds in the neighbourhood of 600 ft. per second at large angles, and it is clear that the distribution of low pressure over the upper surface cannot continue indefinitely. It appears, however, that airscrews so far designed have been free from any marked effect of this nature. The efficiency estimated has been attained in practice, although designers to a certain extent miscalculated the power required to drive airscrews as the speed of the blade tips was increased. The error cannot, however, be ascribed to the effects of compressibility owing to uncertainty as to many other factors involved. On the whole the method of aerodynamic analysis led to sufficiently accurate design.

The screw-propeller as a mechanism for the transmission of power is convenient and efficient. In the airscrew narrower blades can be used than in the marine propeller, and efficiencies as high as 85% have been attained with airscrews of high pitch and large diameter, smaller fast-running airscrews giving efficiencies of 75 per cent.

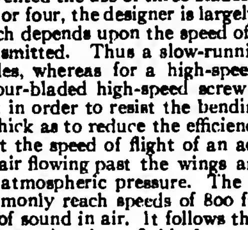


FIG. 15.—Variation of Thrust, Torque and Efficiency of an Airscrew with forward speed at constant rate of revolution.

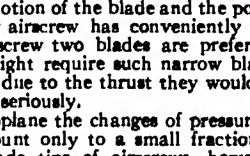

FIG. 15a.—Variation of Thrust at constant Torque.

Owing to the light weight and high tensile strength of timber for its weight, the designer has found in wood his most convenient material. African walnut has proved the best timber when the stresses are most severe. Honduras mahogany is satisfactory for most purposes. Spruce and poplar have also been used, but are not suitable for higher powers and speeds. The screw is constructed of planks, or laminations, about an inch thick, glued together and cut to shape. The grain of the wood should be straight and run as far as possible along the blade. The method of construction secures a good approximation to this requirement. Timber has the advantage of large hysteresis and consequent power of damping vibrations. The Wright brothers' airscrews were made of spruce cut from a single piece of timber. An interesting design appeared in 1913 in the "Garuda" airscrew, of laminated wood construction with the blades tilted forward so that to a large extent stresses due to rotation neutralized those due to thrust. The forward tilt was obtained by bending the laminations during manufacture, a rather questionable practice. This method of balancing stresses has not

been developed beyond carrying the most forward lamination to the tip of the blade and succeeding laminations to smaller radii, owing to the method of construction and the nature of the material used. It has recently been stated that this forward tilt renders the blade liable to twist under load.

The stresses in the blades have been calculated by crude methods which give an approximation to the stress along the grain. Fracture has, however, almost invariably occurred across the grain, in the earlier airscrews, by failure of the glued joints. Workshop practice has now so far improved that the strength of glued joints is equal to the strength of even hard woods across the grain. The evident need for knowledge of torsional stress in an airscrew blade led to the practical solution by G. I. Taylor and A. A. Griffith in 1916 of the problem of torsion of prisms of any section. The mathematical equations had already been stated and the new development was the provision of an experimental method of solution. Theory can now indicate the shape of blade required to avoid twisting under the loads imposed in flight. Apart from the reduction of stress, this is of great value to the designer, who cannot with any certainty predict the performance of an airscrew if the blades twist in an unknown manner in flight.

In order to protect the blades from moisture the airscrew is varnished, or painted, and to protect against sand on land and spray on the sea, the tips have in some cases been sheathed in metal, but the practice of covering with fabric (dating from 1912–3) has recently found more favour. Japanese lacquer has also been used as a protective covering.

Several early airscrews (*e.g.* Breguet's) were entirely of metal, commonly aluminium blades bolted to a steel tube, a method only possible with the low powers and speeds of rotation of the period. Blériot crossed the Channel with a small, high-speed, laminated wood screw. Experiments with steel construction have proceeded slowly and steel may in time come into common use. Failure has been largely due to the unreliable nature of welding, and to brittleness produced in the process. For production in moderate quantities, wood requires far less outlay. A modern development is the airscrew with detachable blades, so far in a purely experimental stage. It allows of adjusting the pitch of the blades, if the airscrew has been imperfectly designed or the conditions of operation be altered, and of replacement of a damaged blade without renewing the whole. If the blades are of wood, shorter lengths of timber may be used, but it is doubtful if this can be regarded as an inherent advantage of the system, because the difficulty of attaching wood blades to a centre are probably as great as the difficulty of making a satisfactory joint at the centre of an airscrew constructed entirely of wood. The airscrew whose pitch is variable in flight is a particular case of the detachable blade screw, and the chief difficulty in the design of such a screw for high speeds of rotation is that of making the joint between the blades and the centre.

In Britain and in America airscrews have been tested before use in flight by "spinning" by means of an electric motor. This test has been applied to new designs, to airscrews whose strength has been suspected by an inspector, and to samples taken from batches. The practice was in force in this country in 1914 and has been continued. Flight conditions are not reproduced by the test, because the airscrew is not advancing through the air, and because the crank-effort variation and vibration of the engine are absent. The thrust loading is more severe, the centrifugal loading less severe. Experience has, however, given considerable confidence in the test. In France the only test applied has been a loading of the blades to counterfeit the air forces, without rotation.

III. AERODYNAMICS

Experiments and Calculations on the Principles of Flight.—The recent history of the development of aeronautics rests largely on experiments on aircraft or models of aircraft and their parts. That branch of investigation which is least related to any other subdivision of engineering is the study of the forces which are experienced by a body when moving through the air. The air forces due to motion are dealt with under the general head of "Aerodynamics." A knowledge of air resistances is a primitive necessity in connecting the subject with the much older and well-established subject of "Dynamics."

In dealing with dynamics, the forces acting are frequently given by a simple fundamental law such as the theory of gravitation when accounting for the motion of planets and comets, and very many of the more complex reactions have been worked out. The corresponding fundamental theory of fluid motion has been known for more than half a century, but application to the determination of air resistances has proved to involve mathematical problems beyond the capacity of the times. Recourse has therefore been made to direct experiment, and in the early stages of aeronautical development almost every new idea could be tested. The number of variables under review has now grown so greatly as to exclude such a method on the ground of cost, and a period of fundamental experiment is being entered on. The object of such experiments is to find out what is happening to the air disturbed by the passage of a body in such a way that the results can be applied, with a reasonable degree of approximation, to a large number of related problems. Some success has been obtained in the case of airscrews, where the experimental data are so used that it is unnecessary to test every new design of airscrew. Extension to the aeroplane is gradually taking place.

For the same reason—expense—experiments on models have been used to cover the main field of inquiry, and the costly and frequently dangerous experiments on the full scale have, on the whole, been directed to crucial tests of the validity of the use of models. There has, of course, been a great amount of testing of aircraft in connexion with their value as fighting craft. At the present time, the value of such testing as an aid to design is very limited, detailed analysis being required to indicate lines of progress.

It then happens that the most comprehensive view of the subject of aeronautical principles is obtained from those aerodynamical laboratories which deal with experiments on models, experiments carried out under almost ideal conditions in the artificial air current of a wind tunnel. The theory of the use of models[1] becomes of great importance in aeronautics and has been studied extensively. When the maximum possible use has been made of the theory the position remains one for experiment, and full-scale coöperation is found to be essential for establishing a sound position. The theory of models has great value in showing the correct type of experiment and the method of comparison with the full scale. Finally, it is now known that when certain precautions are observed in model tests the applications to full scale have an accuracy sufficient to give them a high value as an element in progress.[2]

FIG. 16.—Wind Tunnel.

Laboratory Experiments.—(*a*) *The Wind Tunnel.*—The number of first-class wind tunnels in existence in the world in July 1921 was probably between twenty and thirty. Of these, seven were at the National Physical Laboratory at Teddington, three

[1] *Report*, Advisory Committee for Aeronautics, 1909–10, p. 38.
[2] *Report*, Scale Effect Sub-Committee A. C. A., 1917–8, R and M, 374.

at the Royal Aircraft Establishment, Farnborough, and a number distributed amongst the private aeronautical firms of Britain.[1] America has a number of channels of generally similar type,[2] but with a unique example in one instance where the speed of the air current is very high.[3] The oldest of the wind tunnels of importance in the development of aviation is that of Eiffel,[4] and from it in 1909–10 came a number of experiments on wing forms at a time when flying-machines were becoming realities. The Eiffel type of wind tunnel has been used elsewhere and in France a new installation has been erected at St. Cyr.[5] The other European wind tunnels of note are in Italy (Rome), at Göttingen University (Germany) and Koutchino (Russia). Owing to the general upheaval in Russia the last-named laboratory is closed, but it earned distinction in the years of its activity particularly in dealing with interesting experiments on fundamental points in the theory and practice of the day.

In general conception all wind tunnels agree in attempting to obtain a uniformly distributed, non-fluctuating air stream; and the tendency has been to increase the dimensions and the velocity attained in passing from one installation to a succeeding type. Economy of power for a given extension of experimental range is, by the principles of dynamical similarity, more readily obtained with large dimensions than with high speed. The best criterion, other things being unchanged, is the product of diameter and velocity, and judged on this standard the largest installations of the various countries do not differ materially.

At the Royal Aircraft Establishment (formerly called the Royal Aircraft Factory), Farnborough, a speed of 100 m.p.h. (nearly 150 ft. per sec.) is reached in an air stream 7 ft. square. At the National Physical Laboratory a speed of 110 ft. can be produced in a stream 7 ft. deep by 14 ft. in width and forces on a model of the order of 200 lb. are there contemplated.

The larger Eiffel tunnel gives an air speed of 40 metres per second (130 ft. approximately) on a circular section about two metres in diameter. The tunnel at McCook field (America) gives the very high speed of 500 ft. to a circular stream of air about 3 ft. in diameter.

The experimental section of an Eiffel type wind tunnel consists of an air stream as it crosses an open room from wall to wall, through a specially devised nozzle and collector. The National Physical Laboratory type and others use a working section of the stream in the centre of a chute with solid walls. There are no striking advantages of either type so far as can be seen at the present time. The great desiderata are uniformity of distribution of velocity across the stream and freedom from large pulsations. Uniformity of distribution is almost automatically secured by using a straight air stream. Once curvature has been introduced by the turning of corners the difficulties of producing uniformity are formidable. On the other hand the delivery of large volumes of air—nearly half a million cub. ft. per minute in the large tunnels—requires special consideration if large eddies in the room with consequent pulsations in the flow are to be avoided. There is an opinion, supported as yet only by crude experiments, that the N.P.L. type of channel is somewhat less fluctuating than the Eiffel type. For the delicate adjustments required in the measurement of stability coefficients high value attaches to the steadiness of the air stream.

In dealing with efficient wing forms, where the lift may be more than 20 times the resistance, it is important that the direction of the air stream be accurately known and remain fixed; one-tenth of a degree is considered to be the maximum permissible error. It is found by experience that in a parallel walled channel the wind sets itself parallel to the walls with the accuracy desired. Freedom from large variations of velocity across the section depends not only on the straightness of the chute but also on the distance over which the air has been in contact with solid walls. From some experiments by Stanton it appears that the final distribution of velocity in tubes is not reached for some 20 to 50 diameters behind the open end. On the score of space required and power needed such proportions are unrealizable in wind channels and in other respects would be disadvantageous. Some variation of velocity distribution from point to point along a wind channel is then to be expected, there being a retardation of flow at the walls and an acceleration in the centre. This change of flow is accompanied by a fall of static pressure along the working section of the channel. For experiments on wings, struts, etc., these departures from uniformity are unimportant but in the case of long models of airship forms there is introduced a spurious resistance large in comparison with that proper to the airship model. It has been suggested, and experiments are being carried out to give effect to it, that the objectionable effects of the wind channel might be minimized by the substitution of a slightly diverging chute in the working section for the usual parallel part. It appears to be possible by such device to increase substantially the ease and accuracy of tests on airship forms.

The motion of the air in the wind tunnel is eddying and on this account a difference from motion through still air exists. So far, however, no suspicions have been aroused as to the inapplicability of model tests on this ground. Some eddies produced in the working of a tunnel are worthy of mention. If light sawdust be sprinkled over the floor of the building housing a wind tunnel, below the intake, it will be noticed that isolated miniature whirlwinds are produced. Some of these are vigorous and the base will clear a track amongst the sawdust whilst the core extends upwards to the tunnel intake. The spin in such eddies is great and the effect of the forces experienced by a body in the air flow is considerable. Being spasmodic, the effect is easily differentiated from that of the mean flow and an observer at an aerodynamic balance is conscious of a sharp blow on his apparatus. To eliminate these whirlwinds sufficiently a honeycomb is placed across the intake, the cells being small compared with the dimensions of the whirlwind. Some 10 % to 20 % of the energy of the power plant may be dissipated by the frictional resistance of the honeycomb and some appreciable length of tunnel is required to permit of the levelling-up of the flow before reaching the working section.

The design of a wind tunnel will be seen to involve much study if more than a very moderate degree of refinement of experiment be contemplated. The following brief description of a tunnel introducing modern knowledge may be of interest (see fig. 16).

The wind tunnel is housed in an unobstructed chamber a little longer than itself, a space of one and a half diameters between the intake and wall being sufficient for the satisfactory admission of air from the chamber to the tunnel. The cross section of the room should be 25 to 30 times that of the channel, otherwise the return flow of air from delivery to intake will produce fluctuations of undesirably large magnitude. The tunnel proper is straight and is placed symmetrically in the building, this being effective in securing symmetry of air flow in the working section. Taking the diameter of the section—whether square or circular—as a standard, the tunnel would have an overall length of 10 to 15 diameters made up of a parallel working section and intake four or five diameters long, having a rounded entrance and honeycomb, a cone connecting this working section to a circular race enclosing the airscrew, which may be of similar length, and a discharge section to the end of the room.

The airscrew giving steadiest flow is one of small pitch-diameter ratio but otherwise similar in characteristics to those used in aerial locomotion. The pitch-diameter ratio may be 0·4 upwards, the higher values giving rather greater economy of power and less steadiness. With careful design of airscrew and cone the divergence from channel to airscrew can be made large with resulting economy of power and no loss of steadiness.

The most modern method of dealing with the delivery stream is to divide the building into two parts by an openwork brick wall. Eddies in the return flow are thereby broken up to dimensions which do not greatly affect the steadiness of the air when it again enters the intake. In one instance, in addition to the partition wall, there is a structure closely surrounding the delivery from the airscrew; this delivery is in the form of a jet which impinges on the end wall of the building, and splashing over it, reaches the corners and forms rollers along the four walls. The structure over the jet is designed to break up the stream more completely than the porous wall alone. Instead of the free jet spreading at the wall it is distributed through holes in the covering structure, the spacing being such that equal volumes of air are delivered through each unit of area of the distributor. The number of openings per unit area is small near the wall of the building and increases to cover the whole area just before the airscrew section. It is possible to reduce the velocity at which the air returns to the room to 5 % of that in the jet without the introduction of appreciable back pressure at the airscrew.

Methods of Measurement of Velocity of Air.—Having secured uniformity of distribution and a degree of steadiness sufficient for the type of experiment to be performed, it is necessary to be able to measure the air speed. No simple means is known of obtaining a standard of reference using a wind channel alone, and only one measure—possibly two—of absolute air speed appears to have been made under precision conditions. The particular measurements made on a whirling arm and in the William Froude National Tank at the National Physical Laboratory

gave a standard anemometer which is easily maintained and reproduced and which is accepted throughout the world.

The essential parts of the anemometer are an open-ended tube facing the air current and a parallel walled tube with its axis along the wind, the walls of the tube being perforated by small holes. The open-ended tube is usually referred to as a " pitot " tube, the name being that of one of the early users, whilst the perforated tube is designed to give what is called " static pressure." If the perforations of the static pressure tube be some six diameters behind the closed end it appears that all such tubes give the same reading, independently of size from a fraction of a millimetre upwards, and that the pressure inside the tube is the same as that on a body moving with the air stream. The pressure in the pitot tube is higher than that in the static-pressure tube and the difference, being due to the motion of the air and the stoppage of a central stream by the pitot tube, is usually referred to as " dynamic pressure " or " pitot head." The size of the pitot tube is unimportant and there is little difficulty in reproducing the standard tubes so that they agree with each other within a fraction of 1 %. This represents generally the order of accuracy of aerodynamic measurements, but for certain simple comparisons of force and speed an accuracy of 1/5 % is attainable.

The experiments on the whirling arm at the National Physical Laboratory showed that the dynamic pressure of the anemometer was proportional to the square of the speed through the air. On physical grounds it is known that the dynamic pressure is also proportional to the density of the air. So long as the compressibility of the air does not enter into the effects of motion, the constant of proportionality is found to be equal to one-half, with a probable error of the order of 1/10 %. The extreme range of speed was from a few in. per sec. to 50 ft. per second. On the principles of dynamical similarity, to be explained later, experiments at a speed of 20 ft. per sec. in water can be used to give information as to what happens at a speed of 250 ft. per sec. in air. Using the William Froude National Tank for the purpose, the dynamic pressure of the " pitot-static " tube anemometer has been calibrated to within 1 % up to speeds of 250 ft. per sec. in air.

Over the whole of this range the formula for dynamic pressure given by

$$p = \tfrac{1}{2}\rho v^2\left(1 + \tfrac{1}{4}\frac{v^2}{a^2}\right) \qquad (1)$$

is an accurate representation of observations on the pitot tube anemometer. In this formula, p is the pressure in force per unit area, ρ the mass of unit volume, v the velocity of the air past the pitot and a the velocity of sound in undisturbed air at the place. So long as all the quantities are measured in a self-consistent set of dynamical units the equation is satisfied. The second term in the bracket will be seen to be small in comparison with the first up to speeds of 200 ft. per second. The velocity of sound being a little more than 1,000 ft. per second it will be seen that the second term is less than 1 % of the first within the range considered. This 1 % is a measure of the effect of the compressibility of air and illustrates a general rule—that, for the purposes of aeronautics, air may be considered as an incompressible fluid. The statement is far from true as applied to the motion of a shell fired at usual velocities and may need modification in aeronautics when applied to airscrews. In ordinary practice the tip speed of an airscrew is upwards of 600 ft. per sec. and a few experimental forms have been made to reach tip speeds of 1,200 ft. per second. In the former case the effects of compressibility have not yet been disentangled from other effects, whilst in the latter some preliminary observations show marked changes of type of flow as a result of high speed and the introduction of modifications due to compressibility of the air.

Dynamical Similarity.—The understanding of the laws of air motion in aeronautics and gunnery has been greatly assisted by the theory of dynamical similarity. An early formula was given by Lord Rayleigh[1] and had a marked influence on progress, not only in Britain but abroad. In the later publications of the Advisory Committee for Aeronautics numerous references are made to aeronautical applications of the principle.

All the world is familiar with the idea of similarity in some form or other and there is little difficulty in appreciating the statement that human beings are similar to each other or, more accurately, are nearly similar; the horse would not be included so readily in the category of animals similar to man. The idea of dynamic similarity extends to motions what is more usually applied only to concrete bodies. Motions may be exactly similar, nearly similar, or very different, and in the case of an invisible fluid like air the eye is no guide to comparison. It is true that air may be coloured by smoke and the motion followed and that some work has been carried out on such basis. When it is found, however, that the fluid may be changed without loss of essential characteristics of the motion, a new line of attack is opened and the study of the motion of water or any other fluid will give the essential information. A striking experimental investigation of the reality of the law of equivalence in certain cases was made at the National Physical Laboratory. The motion of air past a square plate was observed and photographed.[2] Smoke admitted to the current showed fluid impinging on the plate and spreading in the water. At a very low speed it was easy to detect a winding of the air round two axes roughly in the direction of the stream. A section of the stream across these axes would have shown particles moving in spirals winding inwards. This was a permanent state. At a higher speed a very noticeable change occurred in the type of motion. Instead of the spirals retaining a steady position, the smoke showed instability had occurred, and periodically loops formed across the two axes, broke away and travelled down stream. It is known by the principles of dynamical similarity that it is possible to produce similar flow in water. Exact conditions for the second experiment follow from those of the first. Further photographs[3] show that the comparison of types of flow is exact within the limits of observation. Neither of the motions described is calculable and the principle of dynamical similarity offers no assistance to understanding why an eddy occurs or what its type will be. It says, quite definitely, that if a given type of motion, eddying or otherwise, exists under certain circumstances, there are sometimes a great number of other circumstances in which the same type of motion must occur, and it lays down in precise terms the other circumstances in their relation to the given type. The instance given above related to change of fluid; other changes might be those of velocity or size. Clearly the change of size covers the relation between model and full scale.

The applications of dynamics to similarity depend on fundamental theories. The common ground exists in Newton's laws of motion but superimposed on this common ground are a number of special cases. In investigating the motion of fluids at ordinary velocities, physicists have identified the property of viscosity; at high velocities compressibility matters and so on. The physical properties of fluids and the quantities involved in motion are expressed in terms of numerical factors and dimensions, *e.g.* 10 ft. per sec. means a velocity of a certain magnitude, the numerical factor 10 and the dimensions ft. and sec. being necessary to give full meaning to the idea of the particular velocity. If a complete dynamical equation be written down it must, if true, satisfy the condition that the numerical values of the two sides of the equation are equal and that, independently, the dimensions are equal. The latter point may be sufficient to give useful mathematical form to the physical ideas. For example, imagine an aeroplane to be gliding down through still air at some known speed. The resistance or drag will depend on its shape and size, its speed, the density of the air and the viscosity of the air. For the moment it will be assumed that the drag is dependent only on the quantities enumerated.

Force has the dimensions $\frac{\mathrm{ML}}{\mathrm{T}^2}$ where M is the symbol for mass, L for length and T for time. Velocity, v, is represented by $\frac{\mathrm{L}}{\mathrm{T}}$, density by $\frac{\mathrm{M}}{\mathrm{L}^3}$ and viscosity by $\frac{\mathrm{L}^2}{\mathrm{T}}$. (See footnote [4])

Expressed in the form of an equation the assumptions so far made amount to

$$\mathrm{R} = f(\rho, l, v, \nu) \qquad (2)$$

where R is the resistance, l a typical linear dimension of the body and f a functional form which depends on the shape of the body. It is common to include in f the presentation of the body to the wind as well as its shape, but this can be excluded at will by introducing angular coördinates into the arguments of the function. The principle of dynamical similarity states that f may only have such a form as will make the dimensions of the two sides of (2) agree. For methods of finding the most general expression for f, consistent with dimensions, reference may be made to textbooks, etc.[5]; it is found that (2) cannot have a more general form than

$$\mathrm{R} = \rho\, l^2 v^2 \mathrm{F}\left(\frac{v\,l}{\nu}\right) \qquad (3)$$

[1] Advisory Committee for Aeronautics, 1909–10, p. 38.

[2] Advisory Committee for Aeronautics, and *Applied Aerodynamics*, L. Bairstow.

[3] *Ibid.*

[4] The coefficient of viscosity used in dynamics is denoted by ν and referred to as the " kinematic coefficient of viscosity." The other common coefficient μ is related to ν by the equation $\mu = \rho\,\nu$.

[5] *Applied Aerodynamics*, L. Bairstow, p. 380.

No dynamical equation depending on the quantities mentioned earlier can exist which is not included in (3). For the purposes of comparison of resistances it has been found convenient by the aerodynamical laboratories to tabulate the value of $F\frac{vl}{\nu}$ for various bodies and to use the symbol k_D for it. Equation (3) may then be written alternatively as

$$F\left(\frac{vl}{\nu}\right)=k_D=\frac{R}{\rho l^2v^2}\text{——————}(4)$$

and in this form several points of importance are evident. To make the case specific, consider the resistance of a sphere in air as obtained from a wind-tunnel measurement. If the dimension l be identified with the diameter d of the sphere it will be noted that $\frac{R}{\rho l^2v^2}$ is an experimentally determinate quantity and from it values of k_D are determined. An examination of the dimensions of k_D will indicate that they are zero; the coefficient is therefore a pure number and so of international validity. Another method of statement would be to say that the numerical value of k_D is independent of the system of units used so long as the system is self-consistent. Measurements of force may be made in dynes, mass in grammes, lengths in centimetres and time in secs. to meet the standards of the physicist. Alternatively the engineer may use the force unit of lb. weight, the slug as a unit of mass, the foot for length and the sec. for time, or, if he prefers it, the force unit of poundal, the mass unit of pound, and the foot and second. In all cases the tabulated values of k_D would be identical. There are further advantages of the system; k_D is independent of the air density and for most aeronautical purposes almost independent of size and speed, so that comparison between model and full scale is readily made by comparison of the corresponding values of k_D. The extent to which the two agree is a measure of the utility of experiments on models.

Equation (4) also shows that k_D depends on a single variable $\frac{vl}{\nu}$, not separately on v, l or ν. On theoretical grounds alone therefore we may say—for our special assumptions—that k_D will not change if the velocity of the same body be doubled in a fluid having twice the viscosity. The kinematic viscosity of air is 12 or 13 times that of water at ordinary temperatures and hence the resistance coefficient will be the same if the velocity of air be 12 or 13 times that of water. Stanton has shown that this is true for smooth and rough pipes by testing with the two fluids in the same apparatus.[1] The law was used in the calibration of the pitot-static pressure tube.

$\frac{vl}{\nu}$ may be kept constant in many other ways; if air be the fluid used in two experiments, then v and l may vary so long as the product is constant. A model aeroplane to one-tenth scale would give a resistance coefficient on test equal to that on the aeroplane at one-tenth the speed. Since the speeds of flight reach 200 ft. per sec. this law is inapplicable to the complete aeroplane, for compressibility of the air would be very important in the model test at 2,000 ft. per second. In testing streamline struts or wires, it is easily possible to make models larger than the reality and so to extend the equivalent speed from that of the wind tunnel to that of flight.

It should be noted, however, that failure to satisfy the law of corresponding speeds, *i.e.* vl = constant, does not necessarily imply failure to obtain similarity of flow between model and full scale. In most of the experiments known to us, resistance varies very closely as the square of the speed and the hypothesis that an exact law existed is worth examination.

Since R varies as v^2 it follows from (4) that k_D is independent of v and further that k_D must then be a constant for all values of $\frac{vl}{\nu}$. In such a case the law of corresponding speeds is of no importance, for k_D can be deduced from a test at any speed on any size of body. It needs little effort to see that if R varies a little from proportionality to v^2 the motions in model and full scale will be nearly similar and that the function $\frac{vl}{\nu}$ is relatively unimportant. It is on this variation from strict theory that aeronautics depends in many applications of model results. Since there is no absolute theoretical sanction except in the case of corresponding speeds, the identity of the values of k_D on the model and full scale must be tried out in a sufficiently large number of typical cases if reliability is to be established. This has in effect been done for aeroplane wings.

It is exceedingly difficult to determine from flight experiments the resistance of the wings of an aeroplane, for the flying apparatus must be complete with body, undercarriage, airscrew and engine, all of which materially affect the resistance of an aeroplane. The comparison of the pressures at chosen points on an aeroplane wing in flight and on a model of it in a wind tunnel is far less difficult and has been made.[2] The theory which led to equation (4) leads also to the conclusion that the pressure divided by air density and square of speed is a function only of $\frac{vl}{\nu}$. Special photographic anemometers[1] were made by the Royal Aircraft Establishment for use in flight and the pressures over a section of the upper and lower wings of a biplane were measured.

[1] Advisory Committee for Aeronautics, 1911–2, p. 41.

[2] *Report*, Scale Effect Sub-Committee, A.C.A., 1917–8, R and M, No. 374.

The types of variation of pressure on the full scale are faithfully reproduced by the model and in three of the four comparisons the actual numerical agreement is complete within the accuracy of measurement. The difference on the fourth comparison has not been explained and some doubt exists as to its reality. Repetition of the experiments has not yet been made. Generally, however, it is clear that in heavier-than-air craft the use of models is amply justified. For airships the lack of full-scale experiment precludes any statement of value.

In the course of the investigations of the variations of k_D with speed and size it was found that changes of appreciable magnitude occurred at the lower speeds of wind tunnels but that the values tended to a limit. It is the value of k_D at the limit of capacity of wind tunnels which is taken in default of correcting factors determined from a comparison between full-scale and model experiments. On the score of cost it is not practicable to increase the size of wind channel or the speed of the wind indefinitely and the highest value of vl appears to be obtained most economically by large size rather than high speed. There are some other advantages of size; the completeness of detail possible increases with the size of model and one of the claims in favour of the large 7 ft. x 14 ft. channel at the National Physical Laboratory is that the model will be so large that an airscrew can be fitted to it and the combination of airscrew and aeroplane tested under conditions very closely resembling those in flight.

The Effect of Compressibility on the Motion of Air.—The law of corresponding speeds expressed by the relation $\frac{vl}{\nu}$ = constant is peculiar to the assumptions made in obtaining (4) as to the experimental factors which have appreciable effects on resistance. There is an indefinitely large number of laws of corresponding speeds, each law being applicable under limited conditions. The method of finding the appropriate law is clear; the process begins with a statement of the physical quantities and measurements involved and concludes when an equation of the correct dimensions has been found. The conditions may be so complex that the answer, when obtained, is of little value; in general the theory of dynamical similarity is useful only when the number of important variables is less than five.

The difficulty here indicated can be seen, if, instead of limiting the problem to a fluid characterized by density and viscosity only, an extra property defining its compressibility is included. There are various ways of expressing compressibility and the most obvious would be through an elasticity modulus. Density is included already in the properties considered, and the velocity of sound in a fluid is determined by the ratio of the modulus of elasticity to the density. It has then come to be usual to assume that the velocity of sound a is a convenient variable when investigating the effects of compressibility of a fluid on the resistance to the motion of a body through it.

The equivalent to equation (2) for the extended problem is

$$R=f_1(\rho, l, v, \nu, a)\text{——————}(5)$$

and restricting the form of f to that which satisfies the theory of dimensions

$$\frac{R}{\rho l^2v^2}=k_D=F_1\left(\frac{vl}{\nu},\ \frac{v}{a}\right)\text{——————}(6)$$

To satisfy the theoretical conditions which guarantee the constancy of k_D it is necessary to satisfy simultaneously the equations

$$\frac{vl}{\nu}=\text{constant},\qquad \frac{v}{a}=\text{constant}$$

for such variations of size, speed and fluid as are at disposal. Once the fluid is specified, ν and a are given and no law of corresponding speeds exists. Various proposals have been made to use a gas such as carbonic acid in one experiment and air in another, but little use appears to have been made of (6) in the form given.

The formula for the pressure due to a pitot tube anemometer—(1)—is a particular case of (6). That the form of (1) agrees with (6) can be seen by an expansion of the functional operator of the latter in powers of $\frac{v}{a}$, using Maclaurin's theorem. Such an expansion will be useful so long as the effect of compressibility is small and the argument $\frac{v}{a}$ small. There is a further simplification in the case of the pitot tube since the resistance does not depend measurably on $\frac{vl}{\nu}$. From experiments on the issue of steam from the nozzles of turbines and the measurements of pressure on a shell in flight it appears that in many cases

$$\frac{R}{\rho l^2v^2}=F_2\left(\frac{v}{a}\right)\text{——————}(7)$$

is a type of formula applicable to the maximum possible pressure on a moving body for speeds ranging from a few in. per sec. to 2,000 ft. per sec. and upwards.

[1] *Report*, A.C.A., R and M, No. 287, p. 504, 1916–7.

It is possible that a correcting factor will be introduced into the design of airscrews to allow for compressibility of the air. In such a case, resistance coefficients based on (7) would provide the first approximation to a rational formula.

Tests of the Water Resistance of Flying-Boat Hulls.—Applications of dynamical similarity extend over the whole range of physics and an exhaustive discussion would lead far away from aeronautics. One other illustration is required to show the origin of the law of corresponding speeds applied in naval architecture to surface-moving craft. Experimentally it has been found that the resistance of surface craft at high speeds depends greatly on the generation of waves. If attention be concentrated on this new aspect of resistance it will be found—by methods already indicated—to give the law of corresponding speeds associated with the name of Froude.

At any point of a wetted surface the pressure is proportional to the head of water above that point and will be increased if a wave crest exists in the neighbourhood. The pressure depends on the head and on the weight of unit volume of the water; alternatively the weight may be expressed as the product of the density of the water and the acceleration due to gravity. Now consider the problem of similar motions between a ship and a model of it. The scale of the model must apply to the scale of the waves if similarity is to exist. It can be said therefore that the resistance depends on a linear dimension l, velocity of test v, density of water ρ and the acceleration due to gravity g. The appropriate formula then follows and proves to be

$$R = \rho l^2 v^2 F_2\left(\frac{v^2}{lg}\right) \text{———————} (8).$$

The law of corresponding speeds is therefore $\frac{v^2}{lg}$ = constant. When dealing with comparisons of motion on the earth's surface, g is constant and the law states that the speed of test for the model varies as the square root of the scale. This condition ensures that the waves in model and full-scale trials shall be similar. Equation (8) may apply in other cases, such as the disturbed motion of model and actual aeroplanes in free flight, the governing factor being the dependence of the motion on gravitational attraction.

Summary of the Aeronautical Uses of Dynamical Similarity.—In measurements of resistance to the motion of a body through viscous fluid the correct law of corresponding speeds is that $\frac{vl}{\nu}$ = constant; this is applicable so long as the velocity of motion is not more than about one-quarter that of sound. At higher velocities, compressibility of the fluid modifies the flow, the changes depending on a further factor $\frac{v}{a}$, *i.e.* on the ratio of the velocity of the body through the fluid to that of sound in the fluid.

If the wave-making resistance alone be considered the law of corresponding speeds for terrestrial surface craft is $\frac{v^2}{l}$ = constant; where resistance depends partly on wave-making and partly on viscosity it is generally assumed that the two can be treated by special assumptions. A very accurate method of treatment of the complex problem does not lead to practicable formulae.

The Resistances of Bodies of Various Shapes.—A somewhat sharp division exists between the resistances of wings and aerofoils and those other bodies with which aeronautics is concerned. In the latter cases the resulting air force is either directly opposed to the motion or is little inclined to it. In the case of wings at the most efficient angle of presentation the resultant force is almost normal to the direction of motion. Since there is always a real drag the direction of the resultant force must fall behind the normal but the amount may be less than three degrees.

It has been found experimentally that all aeroplane wings—whatever their variations of shape—have certain common characteristics. The best ratio of lift to drag is obtained only at a particular angle of attack of the wing to the air and a considerable loss of efficiency is incurred if, as is usual in aeroplanes, departure from this

Fig. 17a.—Flow past wing.
8°. Below critical angle.

angle to the extent of 5° or 6° be permitted. At the highest speed of flight of the aeroplane of 1921 it is improbable that the lift exceeds 12 times the drag, whilst the maximum ratio exceeds twenty.

Apart from efficiency there is a limit to the greatest force which can be obtained at a given speed by a wing of finite area. Omitting very special complex wings for the moment, the limiting force at any given speed is obtained when the wing is inclined at 15° or 20° to the wind. One of the most efficient types of wing form for high-speed

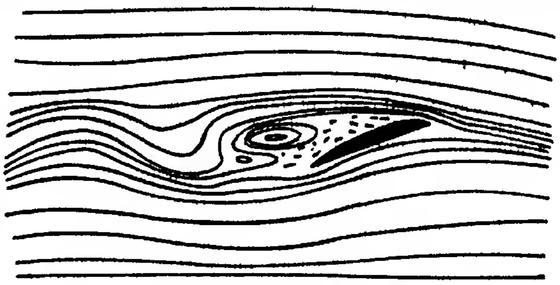

Fig. 17b.—Flow past wing.
20°. Below critical angle.

flight has a limiting lift of about 7 lb. per sq. ft. at a speed of 50 m. per hour. Other forms of fixed section are known which give 12 lb. per sq. ft. at the same speed. The general experience of all experimenters with aerofoils has been that, so long as the shape of the section is invariable, high loading at the angle of maximum lift cannot be obtained at the same time as high efficiency for maximum speed.

Much attention has been paid therefore to flexible and variable wings; if it were possible to vary the area of a wing at will without introducing unreliable mechanism or adding greatly to the weight of the wing structure that solution would offer the maximum aerodynamic advantages. It should be pointed out here, that the addition of weight to an aeroplane in such a place as not to add directly to the resistance leads to an immediate and calculable indirect increase of resistance at a given angle of incidence; the amount may be estimated as about one-eighth of the weight under favourable conditions. So far no satisfactory proposals exist for the mechanical variation of the area of the wings of an aeroplane. More practical success has met the endeavours to vary the section of a wing of given size so as to obtain the advantages of high lift and consequent low speed for alighting and high efficiency at flying speeds. It has already been shown that either condition may be obtained by a wing of fixed section. A further general observation is that the high-speed wing is thin and flat whilst the high-lift wing is thick and greatly curved. Means of constructing flexible ribs for wings to admit of continuous change from one shape to another have been developed and the mechanical difficulties do not appear to be insuperable. A less obvious method of attack has shown greater promise. Mr. Handley Page[1] found by experiments in a wind tunnel that the properties of high lift could be obtained by allowing air to pass through the front part of a wing from the lower to the upper side. By dividing the wing of an aeroplane into a small aerofoil hinged at its leading edge and a large main wing the device becomes both mechanically and aerodynamically effective.

The motion of an aeroplane is now realized to be dominated by other considerations than those of lift and drag and it may be that a particular high-lift wing would be useless because it led to failure of lateral control at low speeds. This point is of growing importance and aeroplane design can no longer ignore the complex interactions of aerodynamic properties. For this reason it may be anticipated that the full advantages from variable wings will not be obtained immediately but that the processes of evolution will be followed. Past history has been simpler; early experiments by Langley (1896) covered the properties of flat plates used as aerofoils and laid the general foundation of practical aviation. Lilienthal later showed that curved surfaces were more efficient than flat ones and attention was given to sections suggested by bird wings, a subject of interest still occupying the minds of designers. With little guidance as to good forms, the early pioneers of flight, Wilbur and Orville Wright, Farman, Blériot and others, introduced wing sections in the period 1906–10 and on these Eiffel based his first series of experiments.[2] Design then began to be regularized. One of the more promising wing sections examined by Eiffel in his wind tunnel at the Champs de Mars, designated "Blériot 11 bis," was adopted by the Royal Aircraft Factory for the BE2A. In 1911, the National Physical Laboratory adopted this form as the starting-point for systematic variation of wing form. In the series of experiments which followed,[3] the thickness of the wing was changed, also its shape on upper and lower surfaces and the bluntness of the nose, and in each case measurements of lift and drag were made. From this series it was possible to make a rational choice of wing section to fit the conditions of the day. The absolute maximum of aerodynamic efficiency demanded a wing too

[1] *Jour. Royal Aeronautical Society*, 1920.
[2] *Résistance de l'air et l'Aviation*, 1910–1.
[3] A.C.A., 1911–2, pp. 73–77.

thin for structural reasons and the Royal Aircraft in the early days of 1913 designed the RAF6 wing on the basis of these experiments for the development of the aeroplane BE2. At a later stage, as engines of greater power were produced; further experiments led to improvement of wings at small angles of incidence and RAF6 was replaced by RAF15 (May 1915). It was found that the advantages of the latter at high speeds were appreciable in spite of the increase of wing area necessary to maintain a reasonably low landing speed.

Many attempts have been made to introduce new wing forms and those showing value on preliminary test have been investigated. It has invariably been found that guesses have been inferior to the results of systematic investigation. In order to facilitate comparison all results of wing tests are—in Great Britain—reduced to a standard form. Different expressions are common in France and America but neither of the latter is international in the sense of being non-dimensional. In accordance with principles of dynamical similarity, the measured forces, lift and drag, have been divided by air density, wing area and sq. of speed in order to deduce lift and drag coefficients. A centre-of-pressure coefficient is obtained by expressing the position of the centre of pressure by the ratio of its distance from the leading edge to the chord of the wing. The results are usually shown in curves as well as tables and, if uniformity in scale be adopted for the curves, comparison of wings is greatly facilitated, since superposition immediately indicates the relative advantages and disadvantages.

It is clear to most workers in the subject that the angle of incidence of a wing is a convenient but arbitrary variable. A more useful relation than lift to angle of incidence and drag to angle of incidence is that of drag to lift, and it is very common to find in the records of the aerodynamics laboratories the value of drag coefficient plotted on a base of lift coefficient. The idea was in effect used by Eiffel in 1910 in a system of polar diagrams. When comparing wings for a given duty a still further variation is sometimes made; the area of a wing depends on the specified landing speed and on the maximum lift coefficient. Only when both these quantities are included can the criterion be of greatest value. If it be presumed that the condition of prescribed landing speed is to apply to an aeroplane with different wings it can be shown that at other speeds the lift coefficients of the respective wings will be proportional to the maximum lift coefficients. Hence a curve of drag coefficient on the ratio of lift coefficient to maximum lift coefficient has direct uses.

Further elaborations have been used, one of which, due to the Royal Aircraft Factory in 1911,[1] is equivalent to the plotting of horse-power on a basis of speed. A new point is thus brought into prominence for it is seen that the choice of wing form to meet given requirements is affected by the resistance of the rest of the aeroplane. Brief notes on the character of this additional resistance will be made at this point.

The aeroplane as a whole is made up from various parts: wings for support; body for holding the engine, pilot, load and control organs, and the undercarriage for leaving the ground and alighting. The same organs are required by float seaplanes and amphibians but in the boat-type seaplanes the body and alighting gear are combined into one structure. The wings themselves are usually supported by struts and wiring which add to the resistance and there is a disposition to test and fit wings which are designed to be strong enough to support the weight of an aeroplane without external bracing wires. It is desirable here to emphasize the fact that the result may not be an effective reduction of resistance owing to the less advantageous types of wing section which must be used and to the greater mechanical difficulties of construction.

The resistances of the body and undercarriage are easily appreciated; both vary very closely as to the square root of the speed and are scarcely changed by alteration of the angle of incidence of the aeroplane. At high speeds the added resistance is roughly equal to that of the wings whilst for the most efficient flight the proportion is more nearly 1 to 2, the wings having the greater resistance. There is a loss due to the engine which is not quite so evident as that due to the body. If water-cooling be adopted, the engine may be totally enclosed and so have no direct effect on the air flow, but in order to maintain the cooling, radiators in the wind are required. It does not matter whether the engine be air-cooled or water-cooled, a certain minimum resistance to motion must be incurred to provide the cooling. Experiments have indicated a relationship between the heat dissipated from a hot surface and the skin friction given by the motion of a fluid over that surface, and the best known radiator is the honeycomb type. Disturbance of the air by a cooling surface which is such that the motion is violently eddying involves a higher resistance for a given dissipation of heat.

The placing of the radiator in the wind near the aeroplane may have important secondary effects. The body is made to approach a streamline form as closely as possible in order to reduce its resistance and the approach to the best results is found to depend greatly on the choice of shape. The magnitude of the possible effects of shape on resistance is most clearly shown by experiments on airship forms. The resistance of an airship envelope is only from 1 % to 2 % of that of a disc which would cover the section at the maximum diameter. It is true that the aeroplane body is far removed from this condition but it is still sufficiently fine to have its resistance increased by an unsuitable disposition of radiator. There is little systematic knowledge as to the best arrangement, and the problem of engine-cooling and body form remains one of engineering difficulty and uncertainty.

Performance of Aeroplanes.—Rapid development—also costly—was facilitated by the construction and test of numerous aeroplanes for war purposes. Not until 1917 did the measurement of engine power and aeroplane performance in Britain reach the stage of generality and accuracy necessary for the purposes of estimate and prediction. Other countries entered the field at still later dates and it will be seen that aviation is still in early infancy. Progress is now less rapid, the main aerodynamic features having been brought to a state at which the work of all the better designers produces nearly the same result. So true is this statement that curves can be drawn relating engine power to speed of flight, rate of climb and total weight curves which show what a designer can attain but rarely exceed. The greatest changes in 1917–21 were in the power plant and here limits are becoming clearly discernible. The changes in the weight of the aeroplane structure due to more advantageous use of material were also small, and in all directions new advance can only be won by assiduous study. The period of striking progress is over and has given place to one in which greater training and knowledge are required than in the past. This is particularly true in matters relating to the reliability and safety of aircraft.

Stability.—The idea of stability as applied to motion is very old and standard methods of dealing with mechanical problems were gradually developed by the mathematicians of the last century. Laplace applied his knowledge to an examination of the stability of the solar system, *i.e.* he accepted the theory of gravitation as accounting for observations and made an extension to see whether the motion was permanent or in a state of change. The ideas of stability are quite different from those of performance and at the present day it is safe to say are not understood by designers with the degree of intimacy which leads to incorporation in design. It is true that some rough generalizations exist and are acted upon; by placing the centre of gravity of an aeroplane very far forward longitudinal stability is ensured whilst a rearward position tends to instability and danger. Similarly, the fin's dihedral angle on the wing is known to affect lateral stability. Present-day (1921) aeroplanes border on neutral stability for the conditions of straight forward flight and this has come about by trial and error, corrected by the likes and dislikes of a pilot during aerial fighting. So long as the pilot be alert and the aeroplane of moderate size, say less than 6,000 lb. weight, it is possible to control the craft in the air in the condition in which it leaves the works. The few attempts to make very large aeroplanes, 20,000 to 50,000 lb. in weight, have led to early disaster owing to the inability to approach, on such scale, the necessary degree of refinement of control and stability. Alternatively it may be said that the attempt to develop large aircraft has overstepped the reasonable limits of caution and has placed on the pilot a strain which he is physically incapable of withstanding.

Even in the smaller craft there are many which in normal flight require the unremitting attention of the pilot and which if left to themselves for a minute would be in a dangerous and probably uncontrollable condition of flight. This is not a necessary state for an aeroplane and there is no insuperable difficulty, given training, in ensuring, without an appeal to trial in the air, that an aeroplane will fly itself for long periods. The opinion has been expressed that aircraft of the present day would be of commercial value were the obviously removable defects dealt with. Reliability of the engine installation is probably the most urgent need, but following that comes the application of the known theories of stability.

Broadly speaking the quality called stability is readily defined. An aeroplane is taken into the air and a given state of motion produced by the pilot and maintained for some time. This operation does not involve stability but requires adequate control. When flying steadily suppose that the pilot ceases

[1] *See Flight*, Jan. 13 1912, "An Aeroplane Study," M. O'Gorman.

to operate but keeps his muscles rigid and without disturbing the motion deliberately produces a condition in which the aeroplane has to control itself in gusts of small size. If the motion be stable, no great changes will occur as a result of the pilot's relinquishing of control. A small amount of pitching, rolling, yawing and side-slipping, etc., will occur but on the whole the speed of flight and the angle of incidence will remain at the same value as at the beginning; the wings will not change their angle of bank greatly nor the turning increase or decrease.

An instability, and in contradistinction to stability there are many instabilities possible, will magnify the effects of a gust with greater or less rapidity and the motion will depart from the initial state to some other stable state. It rarely happens that this second state is a comfortable one. An aeroplane which is unstable in normal flight will usually be stable upside down and may be so stable in that position as to be uncontrollable. The time taken to pass from one state to another is often only a matter of a few seconds, rarely as long as a few minutes.

In the very early days of flying the problem of getting into the air at all took first place in importance. The aviators of 1908–10 kept a very close watch on the weather and one of them had a standard test for satisfactory conditions. Standing with his feet apart, he dropped a feather from the level of his shoulders and if it fell outside his feet the wind was too great for flying. The record of these early years and the shortness of life of the aviators are sufficient testimony to the consequences of the extreme forms of instability. The revolutionary step which made it possible to keep the air for an hour instead of a few minutes was made by the Wright brothers when they introduced wing warping as a lateral control; there is little reason to doubt the statement that flying still remained an acrobatic feat. A study of the technical papers of the period 1908–14 will show how slowly the idea of banking[1] an aeroplane entered into the development of aviation. It is noted in March 1912 as a possible cause of accident that the pilot "is reported to have endeavoured to rise when making a turn." Not until April 1913 do we find vertical banking by Chevillard followed by upside-down flying and looping by Pégoud in Sept. of that year.

A prominent place in the technical journals was devoted to accidents and a perusal of these shows that all types were liable to fail as late as 1913. A series of accidents to monoplanes occurred in Britain and their flight was suppressed temporarily in Sept. 1912, whilst a committee was formed to investigate causes and to suggest lines of development. The findings of this committee[2] have had a marked influence on British aviation and the paragraph relating to stability is here quoted:—

"The Committee desire to urge the importance of the general investigation into the stability of aeroplanes, whether monoplanes or biplanes. The experimental data at present available are not sufficient to allow a complete theory to be formulated. It is understood, however, that the work of the Advisory Committee has now been carried to the stage at which the problem can be attacked with hope of success, provided that the necessary facilities—a large wind channel in a sufficiently big enclosed space—be put at their disposal, and the Committee recommend that the Advisory Committee be asked to continue the further investigation into the stability of the aeroplane as a matter of great urgency, and more especially to examine the question of inherent lateral stability, suggestions towards the solution of which have been given by the experiments of Lanchester and the calculations of Bryan."

The investigation here started led directly to the stability experiments on RE1 and BE2, a combination of full-scale flights at the Royal Aircraft Factory and model and theoretical preparatory work at the National Physical Laboratory. Before dealing with the results, a return to early times will be made to indicate the position of the theory of stability.

Up to the end of 1909 the chief writers on the stability of the aeroplane were Bryan,[3] Ferber,[4] Lanchester,[5] and Soreau.[6] The most complete method was that by Bryan. The papers all advanced the study of the subject in some measure but the appearance in 1911 of Bryan's book *Stability in Aviation* laid the foundations of the subject as now known to us. About the same time other workers were entering the field, amongst whom may be mentioned Knoller,[7] Bothezat[8] and Reiszner.[9] From that time the theory of stability has been far ahead of practice. Developments have been made to cover circling flight, disturbed motion and the effects of gusts, but all are natural extensions of the theory of dynamical stability as given by Routh and applied by Bryan to the aeroplane. There is little doubt that further extensions will be made as required, but the immediate need is the devotion of existing knowledge to practice to a far greater extent than has hitherto occurred. As in other branches of research the World War has had an adverse effect in curtailing opportunities for reasoned progress.

In March 1913 a report[10] was issued showing the possible applications of the theory of stability in numerical detail. The mathematical analysis cannot be useful unless a number of quantities, known as resistance derivatives, can be obtained from experiment. The report in question represents the first systematic attempt to apply experimental research to the evaluation of the quantities required for application of the theory. A discussion is given of the meaning and origin, from the physical side, of the resistance derivatives and rough estimates were made as to the ranges of the quantities for then existing aeroplanes. For one condition of flight more accurate data were obtained and a table of some 18 derivatives deduced covering the longitudinal and lateral stabilities of an aeroplane in normal flight. There are a number of approximations which assist in the understanding of the relation between cause and effect which were of importance in the infancy of the subject.

By such a preliminary examination on the model scale, the phenomena to be looked for on the full scale were clearly defined. The now well-known "phugoid" oscillation was then unobserved and only indicated by calculations. It is indeed possible that up to that date longitudinal stability did not exist apart from the very special design of Dunne. The mathematical theory indicated quite clearly that special shapes were unnecessary and that aeroplanes of more usual form could be made stable by attention to the disposition of weights and the arrangements of the aerofoil surfaces. In particular, the importance of a dihedral angle on the wings and an adequate fin and rudder were shown in relation to lateral stability.

In the course of the 12 months which followed great progress was made; in a series of papers[11] from the National Physical Laboratory, the effect of varying essential quantities, such as the centre of gravity of the aeroplane, the amount of area of the tail plane, the extent of the dihedral angle, rudder and fin area, etc., was examined in detail. It was shown that partial experiments on lateral stability would fail since there is a relation between the dihedral angle on the wings and the appropriate fin and rudder area.

Further, the exact method of inherent adjustment of an aeroplane to gusts was shown and the details of flight of a longitudinally stable aeroplane in a natural wind obtained. This was done not only for uncontrolled but for controlled flight. By the summer of 1914 the investigation of the effect of natural properties of an aeroplane on mechanical devices for controlling it were being envisaged, but the outbreak of the war broke the continuity and the subject still remains at that point of theoretical development.

In the meantime full-scale experiments were being made at the Royal Aircraft Factory.[12] A few extracts from these reports are of historical value and are here reproduced:—

"Although completely controllable under all circumstances by means of the elevator, it has been found that the BE2A aeroplane, fitted with the old tail plane (TP1) was not stable with the elevator free or even locked. . . . Two methods of experimenting have been adopted:—(*a*) Variation of the section and plane form of tail. (*b*) Variation of the position of the centre of gravity of the aeroplane relative to the position of the wings."

"Experiment (1) with tail (TP1). Area of tail 61 sq. feet. Centre of gravity at 0·38 of the mean chord behind the leading edge. At a height of about 2,000 ft. the elevator control lever was held in a fixed position. After a short time, a steady dive developed, which was allowed to continue so long as it was considered safe by the flier, in this instance during a flight of about 500 yards. There was no tendency for the path to revert to the horizontal. . . . It was found that there was just as much tendency for a steady rearing to be developed as a dive. . . ."

"Experiment (2). Another tail was tried (TP2) . . . A long glide was also made with the elevator locked. During these flights a marked improvement in the behaviour of the machine was obtained, damped phugoids being described. . . . It may certainly be said, however, that with TP2 and the other conditions of this experiment, BE2 was proved to be capable of flying indefinitely with the elevator locked in winds with gusts up to 30 m. per hour."

"Experiment (3). The same tail plane was fitted and the conditions were approximately the same except that the centre of gravity was considerably further back. . . . This very backward position of the centre of gravity, of course, made the aeroplane quite unstable, and increasing dives or rearings were performed almost as soon as the elevator was locked. . . ."

"Experiment (4). The centre of gravity was brought forward and a considerable improvement was obtained. It was now found that even with the elevator free, damped phugoids were obtained. In the absence of gusts at the time, these phugoids were started by movements of the elevator control lever. When the machine had been forced to assume a sharp dive, the control lever was totally released and it was found that after two or three complete oscillations the amplitude became too small to be noticed. . . . The period of oscillations was found to be about 20 seconds."

"Apart from the practical utility of these experiments in developing the particular aeroplane in question their wider significance underlies the fact that they agree with and confirm the model experiments on the full scale both as regards the characteristics of the tail planes and the interference of the main planes with them; and the two sets of experiments give data from which a tail can be designed for any aeroplane to give any degree of longitudinal stability required."

It appears from recent investigation of accidents that the type of instability described above is not avoided in all modern aircraft. The effect of the instability is serious and epidemic failures to control have been traced to this cause alone.[1] Some photographic records of longitudinal motion taken at a much later period will be found as reproductions in the Wilbur Wright lecture[2] for 1919. The actual time required for the testing of longitudinal stability is now so short that the production of records has been made an addition to the older established performance trials. Progress has been steady but rather slow and the influence of the tests is not yet evident in new design.

In the case of lateral stability the records of the early experiments at the Royal Aircraft Factory are of equal or greater interest with those on longitudinal motion:—

"RE1 rolling stability experiments, by Mr. Bush. . . . The wing flap controls were entirely abandoned and the aeroplane was flown 7½ m. with two turns without their use. The rudder was used for steering or was kept straight to avoid complicating the investigation."

"The evolutions of the aeroplane bore out the theoretical expectations. Disturbance by a gust was followed by side-slip towards the low side, which brought the dihedral angle into effect, righting the machine. In both the above experiments the recovery from a roll seemed rather slow, and it was decided to double the amount by which the wings were bent up."

"The results of the above experiments were sufficiently satisfactory to warrant the abandonment of the warp and the use of wings with flaps for RE5 and other aeroplanes in course of design."

"Rotative Stability.—The rotative stability with the rudder in a fixed position was next examined. Up to this point the aeroplane had been usually steered on a straight course, which made recovery quicker. When the rudder is fixed, however, disturbance of level is followed by a turn towards the low side as well as a side-slip. If the directional stability is too great, the increased speed of the outer wing will counteract the restoring effect of the side-slip, and the aeroplane will continue to turn with increasing bank and angular velocity. The manoeuvre if not controlled ends in a spiral dive."

"Dec. 8 1913.—In this experiment, the rudder was adjusted for straight flight and then held fast by the feet, friction of the heels against the floor making absence of movement certain. When all was ready the aeroplane was disturbed by the wing flaps, which were then returned to their normal position. The experiment is rather delicate, as any want of symmetry will cause the aeroplane to be stable when rolled in one direction and unstable in the other. It appeared, however, that the aeroplane was just stable, righting herself slowly."

"Complete stability test.—The aeroplane was flown from Long Valley, Aldershot, to Froyle near Alton, and also from Froyle to Fleet, distances of 6½ and 8 m., without the use of wing flaps or elevator. The wing flaps were left free as usual and the elevator was locked. The flying was very comfortable, and the pilot considered that reconnaissance under these conditions would be considerably easier for a pilot alone."

For normal flight the description of lateral stability given in these abstracts still represents the position. The experiment is still delicate and it may be doubted whether any aeroplane has an appreciable degree of lateral stability. The early work on stability cleared the way to a large extent; the temptation to complex design for safety was removed and dangerous instability rarely exists so long as a pilot is alert. The introduction of aerobatics and the training of pilots to loop, spin, roll, etc., at the same time as it inspired confidence in the ability to control an aeroplane also led to conditions far removed from those of normal straight flight. It was then found that the stability of aircraft under extreme conditions has great importance, particularly when the angle of maximum lift has been reached or exceeded.

A very large proportion of accidents arises from engine failure whilst near the ground. In holding up the nose of the aeroplane whilst attempting to turn back into an aerodrome, the pilot not infrequently stalls the craft and violent lateral instability results. Recovery from the effects of this instability is rare and much study has been made of the phenomenon.

There is now little doubt as to the cause of this instability but the methods of removing it are far less clear. The same cause which produces instability removes the effectiveness of the controls; it is probable that high-lift wings have characteristics antagonistic to those of stability and further investigation of the subject is required before satisfactory design for speeds less than that of stalling can be reached.

More recent papers on various aspects of stability will be found in the reports of the societies and bodies[3] dealing with aeronautics; there are no striking developments but much solid work has been done by a few workers in the subject. There are difficulties in the nature of variation of nomenclature which make the comparison of work laborious and in an attempt to deal with this aspect of the problem of stability the Royal Aeronautical Society, acting as a sub-committee of the British Engineering Standards Association, has drawn up and recommended the use of a particular set of symbols and axes of reference. Still in its infancy as regards application, the subject merits greater attention. It is scarcely likely that the degree of stability—still undefined—thought suitable for military use will be that correct for civil uses. Extreme manoeuvrability is considered to be essential in the first and safety in the second. Whilst not wholly incompatible it is clear that a degree of stability can be introduced without discomfort in a straight and uneventful flying which is disliked for the purposes of aerial fighting. (L. Bw.)

IV. Materials and Methods of Manufacture

The aircraft pioneers, being their own designers, builders and financiers, used the simplest design, manufacture and assembly, and the cheaper materials.

Between 1912 and 1914 came a striving for efficiency; fixed charges were relatively high, and research costs were extremely great for the small output of the day; this conduced to the quest for the best materials and made costly machining to reduce weight and establish types permissible. In the World War the aerodynamic advances made in this way were used, but as bulk production set in before schemes and tools for bulk production existed, aeroplanes had to be made regardless of cost until the tools were evolved.

Standardization of materials, of sizes and of parts and components, notably bolts, nuts, bracing connexions, piping connexions, etc., common to most types of aircraft, had previously to 1914 been started, but was extended in 1915 to cover tubes, bracings, methods of jointing, length of bracings, wheels and axles, airscrew bosses, etc. Also some of the larger components, wings, elevators, rudders, and ailerons, which could be utilized on more than one type, were standardized. Master and workshop gauges were made and distributed to ensure interchangeability. Continuous records of tests led to the selection of the most suitable materials, and to standard specifications. These have been continuously evolved up to the present day, and their dissemination has spread far and wide much acquired knowledge.

The earliest steps in England, or indeed anywhere, to unify such standards were taken by the Royal Aircraft Factory at Farnborough in 1913. They were extended and improved as experience developed under the Aircraft Inspection Department (A.I.D.) in England (towards the end of 1915), and later under the British Engineering Standards Association, which in 1921 was instrumental in founding in Paris the "Comité International pour l'Unification Aeronautique" to internationalize the same work.

Components.—Fuselages, wings, undercarriages, tail planes and controlling surfaces, prior to 1914 were not, save in one or two cases, designed as self-contained units, *i.e.* their manufacture was usually completed during erection into the aeroplane. This involved hand-fitting, trial and error adjustment, constant inspection and slow production, while spares were not interchangeable.

By 1915 each component became a unit in itself, made to limits, corresponding with the connexion points, and interchangeability was safeguarded by the use of jigs and fixtures. By 1919 even components were subdivided into standardized parts, and the assembly of components into a complete aeroplane could be effected after delivery to the field. The jigs and fixtures were usually confined to the location of junction fittings on which the structure was erected. These replaced the fixtures of 1915, which held all members of the component in position during construction, but proved not to be satisfactory, owing to the distortion of the finished piece on removal from the fixture.

Girder types of construction, such as fuselages, wings, etc., were latterly constructed to jigs rather than on fixtures, in order that their truth of erection might be more permanent. Monocoque constructions, however, were always built on cradles or moulds, which definitely determined their final shape; the individual members, being free from initial load, were free from distortion on removal from the mould.

The development of portable gauges (gauge points mounted on tensioned wires) occurred in 1916.

In 1917 component junctions were designed so that all positioning was determined by one joint, clearance in one direction being allowed on the remaining joints; the gauging of components was simplified thereby, and many of the more costly gauges could thus be superseded by simpler ones used in conjunction with a measuring operation.

Woodwork.—Wood is eminently suitable for light construction and for obtaining a rapid output by machining. The mechanical properties and suitability of various timbers were little known in 1913. Bamboo, the lightest timber, was found unsuitable in about 1911; it lacks uniformity in size, and is difficult to connect at the end of members. Ash (*Fraxinus excelsior*) and hickory (*Carya alba, Hickora ovata*) were early used, but hickory is scarce, and variable in its mechanical properties, and ash is heavy as well. Ash is restricted to use where high flexibility and shock-resisting are essential. Silver spruce (*Picea Sitchensis*, Carr.) was introduced in 1913 for spars, struts, longerons and other members, being uniform, light and suitable for machining for weight reduction.

Between 1913 and 1915 accurate information of the strength and elasticity of this timber was acquired. Methods of converting the timber for the various uses were determined in order to eliminate defects peculiar to coniferous timbers, such as spiral grain, cross and diagonal grain, dote or rot, gum pockets, alternating hard and soft grains, low density, wide-ringed timber and brittle or lifeless timber (brash).

The great demand in 1916 in England led to the importation of unseasoned timber, needing to be conditioned for use. The French and Americans had already experience of this. Kilns were erected in England (on the Sturtevant system of drying). Humidities, temperatures and time periods of drying were determined. Control of the moisture-content of timber was found to be essential.

The larger aeroplanes in 1916 and 1917, and the demand in excess of supply for best of spruce of long lengths, led to spars being made of short lengths joined together, the joints being situated at points of low stress. A study of various joints in 1918 led to the adoption

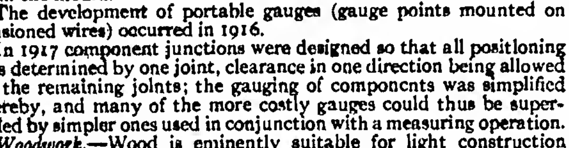

FIG. 18.

of the plain vertical scarf joint with an inclination of 1 in 9, reinforced by bolts through the splice, and bound with fabric (see fig. 18). Shorter timbers glued together as laminations then became permissible for all spars, and defects could thus either be cut out or reinforced. Joints in these laminations, after being admitted for a period, were ruled out in 1919.

To supplement the supplies of silver spruce in 1917 the following timbers were tried in 1918, the peculiarities of each being allowed for:

Quebec Spruce (*Picea alba* and *Picea nigra*, Link.).
White Sea White Deal (*Picea excelsa*, Link.).
White Sea Red Sea Yellow Deal (*Pinus sylvestris*, Link.).
West Virginia Spruce (*Picea rubens*, Sargent).
North Carolina Spruce (when this is the same as West Virginia Spruce, but grown in North Carolina).
Louisiana Red Cypress (Bald.).
Port Orford Cedar (*Chamaecyparis Lawsoniana*, Murr.).
New Zealand Kauri (*Agathis* [*Dammara*] *australis*).
Canadian White Pine (*Pinus Strobus*, Link.).
Oregon Pine (*Pseudotsuga Douglasii*, Carr.).

Cypress, which is very variable, liable to brittleness and unsuitable for glueing, was barred in 1918. Oregon pine, which is liable to fracture under shock, and may split when cut into small dimensions, must be restricted to struts and used in the solid. Small knots in the deals can be allowed in laminations if the knots be distributed to obtain uniformity of the member. Laminated struts were used in 1919, with fabric binding to safeguard against the opening out of joints. Early in 1918 box sections, which have all the advantages of laminating, were used, and their use continues.

About 1915–6 the glues used in the above processes were classified into three grades: (1) the best for airscrews; (2) for less highly stressed joints; (3) for unimportant details. Glue shops were maintained at a constant 70° Fahrenheit. Micro-investigation of glued joints proved the value of carefully preparing the timber and glue; timber was aged to prevent warping, by storing in the 70°-F. rooms for long periods before glueing. Roughing of the surfaces to be glued was adopted to secure keying.

In 1915–6 it was found that if an entire series of laminations were glued in one operation before clamping the first joint would become chilled before the clamping occurred. Later, by using trained crews and special appliances for quick glueing and clamping, the *en bloc* process of glueing with the more rapid output became possible and satisfactory. Where heated-glue rooms could not be used, "liquid" glue or jelly glues (containing an ingredient which delays the setting point of the glue, thus allowing of ordinary temperatures—55° F. to 60° F.—with ample time for assembly of parts) were adopted.

Metal Fittings.—In 1910 fittings for the structures, attachment of bracings, etc., were made of mild steel, a metal selected, no doubt, because it could be worked cold. This was often used in double thickness to ensure against flaws. Oxy-acetylene welding was often used in joints, even in some that were subject to stress. Tubes and plates were welded together to make sockets, and bent to shape without being subsequently normalized. Failures at welds led to the substitution in 1915 of mild-steel drop forgings. These were machined all over to save weight and to get the size accurate to tolerances too small for the stamping industry at that time.

The correct temperature for forging and subsequent heat treatment of the forging in high tensile steel was not currently known. The facilities were lacking, and the control of the temperatures needed was left too much to the estimate of the skilled operative. Stampings brittle and unreliable for use, as well as difficult to machine, were made. In 1915–6 the impact test, long known but little used, was supported by the War Engineering Committee of the Royal Society, and was found valuable for ensuring that the material so tested would bear prolonged shock stress.

By 1917 the call for speedy output led to a reversion from forgings to sheet-metal sockets and fittings, using a low carbon sheet-steel of 26 tons' ultimate tensile strength. The pressings were shaped in jigs which ensured an adequate radius at the bend, and they were normalized to remove strains due to bending or punching. Where complicated fittings were built up of simpler pressings these were riveted and soldered together to avoid welding. Dip-brazing of such constructions came in in 1918, with the advantage that the temperatures could be better controlled than when brazed with a blow-pipe. Such pressings are interchangeable and need less gauging and inspection. Turnbuckles, universal joints, shackles, etc., hitherto machined from the bar, were re-designed for quicker manufacture from sheet metal.

Bracings.—In 1910–1 80-ton steel "piano wire" was much used for bracing the structure, but the fastenings for this had only some 60% of the strength of the wire; the loops stretched, and the structure was soon distorted. Flexible cables spliced on to wiring plates and adjusted by turnbuckles were then used with greater safety, but these also stretched and increased the air resistance, to reduce which wooden fairings were applied to the cables. Solid wires swaged to streamline form, and left thick at the ends for screwing, were made as early as 1911, but they were difficult to manufacture. In 1913 this fair section was abandoned for the elliptical, to allow of rolling instead of swaging the rods, while a special steel and heat treatment evolved by the Royal Aircraft Factory overcame the difficulties. These wires were not generally adopted till, in 1915, standardized aeroplanes led to a demand which warranted bulk production.

Wires of streamline section were swaged, not rolled, because these unsymmetrical sections tend to curve over sideways as they pass out from the rolls. The elliptical-section wires were called "Rafwires," to distinguish them when they were standardized. The screwing of the end of these wires was carried on after heat treatment (at 550° C.). Subsequently the wires were tempered at a lower temperature

"Experiment (2). Another tail was tried (TP2) . . . A long glide was also made with the elevator locked. During these flights a marked improvement in the behaviour of the machine was obtained, damped phugoids being described. . . . It may certainly be said, however, that with TP2 and the other conditions of this experiment, BE2 was proved to be capable of flying indefinitely with the elevator locked in winds with gusts up to 30 m. per hour."

"Experiment (3). The same tail plane was fitted and the conditions were approximately the same except that the centre of gravity was considerably further back. . . . This very backward position of the centre of gravity, of course, made the aeroplane quite unstable, and increasing dives or rearings were performed almost as soon as the elevator was locked. . . ."

"Experiment (4). The centre of gravity was brought forward and a considerable improvement was obtained. It was now found that even with the elevator free, damped phugoids were obtained. In the absence of gusts at the time, these phugoids were started by movements of the elevator control lever. When the machine had been forced to assume a sharp dive, the control lever was totally released and it was found that after two or three complete oscillations the amplitude became too small to be noticed. . . . The period of oscillations was found to be about 20 seconds."

"Apart from the practical utility of these experiments in developing the particular aeroplane in question their wider significance underlies the fact that they agree with and confirm the model experiments on the full scale both as regards the characteristics of the tail planes and the interference of the main planes with them; and the two sets of experiments give data from which a tail can be designed for any aeroplane to give any degree of longitudinal stability required."

It appears from recent investigation of accidents that the type of instability described above is not avoided in all modern aircraft. The effect of the instability is serious and epidemic failures to control have been traced to this cause alone.[1] Some photographic records of longitudinal motion taken at a much later period will be found as reproductions in the Wilbur Wright lecture[2] for 1919. The actual time required for the testing of longitudinal stability is now so short that the production of records has been made an addition to the older established performance trials. Progress has been steady but rather slow and the influence of the tests is not yet evident in new design.

In the case of lateral stability the records of the early experiments at the Royal Aircraft Factory are of equal or greater interest with those on longitudinal motion:—

"RE1 rolling stability experiments, by Mr. Bush. . . . The wing flap controls were entirely abandoned and the aeroplane was flown 7½ m. with two turns without their use. The rudder was used for steering or was kept straight to avoid complicating the investigation."

"The evolutions of the aeroplane bore out the theoretical expectations. Disturbance by a gust was followed by side-slip towards the low side, which brought the dihedral angle into effect, righting the machine. In both the above experiments the recovery from a roll seemed rather slow, and it was decided to double the amount by which the wings were bent up."

"The results of the above experiments were sufficiently satisfactory to warrant the abandonment of the warp and the use of wings with flaps for RE5 and other aeroplanes in course of design."

"Rotative Stability.—The rotative stability with the rudder in a fixed position was next examined. Up to this point the aeroplane had been usually steered on a straight course, which made recovery quicker. When the rudder is fixed, however, disturbance of level is followed by a turn towards the low side as well as a side-slip. If the directional stability is too great, the increased speed of the outer wing will counteract the restoring effect of the side-slip, and the aeroplane will continue to turn with increasing bank and angular velocity. The manoeuvre if not controlled ends in a spiral dive."

"Dec. 8 1913.—In this experiment, the rudder was adjusted for straight flight and then held fast by the feet, friction of the heels against the floor making absence of movement certain. When all was ready the aeroplane was disturbed by the wing flaps, which were then returned to their normal position. The experiment is rather delicate, as any want of symmetry will cause the aeroplane to be stable when rolled in one direction and unstable in the other. It appeared, however, that the aeroplane was just stable, righting herself slowly."

"Complete stability test.—The aeroplane was flown from Long Valley, Aldershot, to Froyle near Alton, and also from Froyle to Fleet, distances of 6¾ and 8 m., without the use of wing flaps or elevator. The wing flaps were left free as usual and the elevator was locked. The flying was very comfortable, and the pilot considered that reconnaissance under these conditions would be considerably easier for a pilot alone."

For normal flight the description of lateral stability given in these abstracts still represents the position. The experiment is still delicate and it may be doubted whether any aeroplane has an appreciable degree of lateral stability. The early work on stability cleared the way to a large extent; the temptation to complex design for safety was removed and dangerous instability rarely exists so long as a pilot is alert. The introduction of aerobatics and the training of pilots to loop, spin, roll, etc., at the same time as it inspired confidence in the ability to control an aeroplane also led to conditions far removed from those of normal straight flight. It was then found that the stability of aircraft under extreme conditions has great importance, particularly when the angle of maximum lift has been reached or exceeded.

A very large proportion of accidents arises from engine failure whilst near the ground. In holding up the nose of the aeroplane whilst attempting to turn back into an aerodrome, the pilot not infrequently stalls the craft and violent lateral instability results. Recovery from the effects of this instability is rare and much study has been made of the phenomenon.

There is now little doubt as to the cause of this instability but the methods of removing it are far less clear. The same cause which produces instability removes the effectiveness of the controls; it is probable that high-lift wings have characteristics antagonistic to those of stability and further investigation of the subject is required before satisfactory design for speeds less than that of stalling can be reached.

More recent papers on various aspects of stability will be found in the reports of the societies and bodies[3] dealing with aeronautics; there are no striking developments but much solid work has been done by a few workers in the subject. There are difficulties in the nature of variation of nomenclature which make the comparison of work laborious and in an attempt to deal with this aspect of the problem of stability the Royal Aeronautical Society, acting as a sub-committee of the British Engineering Standards Association, has drawn up and recommended the use of a particular set of symbols and axes of reference. Still in its infancy as regards application, the subject merits greater attention. It is scarcely likely that the degree of stability—still undefined—thought suitable for military use will be that correct for civil uses. Extreme manoeuvrability is considered to be essential in the first and safety in the second. Whilst not wholly incompatible it is clear that a degree of stability can be introduced without discomfort in a straight and uneventful flying which is disliked for the purposes of aerial fighting. (L. Bw.)

IV. Materials and Methods of Manufacture

The aircraft pioneers, being their own designers, builders and financiers, used the simplest design, manufacture and assembly, and the cheaper materials.

Between 1912 and 1914 came a striving for efficiency; fixed charges were relatively high, and research costs were extremely great for the small output of the day; this conduced to the quest for the best materials and made costly machining to reduce weight and establish types permissible. In the World War the aerodynamic advances made in this way were used, but as bulk production set in before schemes and tools for bulk production existed, aeroplanes had to be made regardless of cost until the tools were evolved.

Standardization of materials, of sizes and of parts and components, notably bolts, nuts, bracing connexions, piping connexions, etc., common to most types of aircraft, had previously to 1914 been started, but was extended in 1915 to cover tubes, bracings, methods of jointing, length of bracings, wheels and axles, airscrew bosses, etc. Also some of the larger components, wings, elevators, rudders, and ailerons, which could be utilized on more than one type, were standardized. Master and workshop gauges were made and distributed to ensure interchangeability. Continuous records of tests led to the selection of the most suitable materials, and to standard specifications. These have been continuously evolved up to the present day, and their dissemination has spread far and wide much acquired knowledge.

ing rods, etc., with good results:—Carbon 35%; Nickel 3·5%; Chromium 0·6–1%.

Difficulties attended the manufacture of crank-shafts for 12-cylinder engines which, in order to reduce the overall length, employed roller main bearings. At first such crank-shafts were produced from billets twisted through 120° at the main journal, which provided only ¼ in. length in which to effect the twist, necessitating so high a twisting temperature that no subsequent heat treatment could restore the structure to a uniform and satisfactory condition. The use of a billet of double width involving a twist of only 60° was then tried, with improved but not entirely satisfactory results. Finally such crank-shafts were produced from a billet first pressed or crinkled to a general crank-shaft form to provide a continuous grain flow throughout journals, webs and pins, and finished finally by drop stamping and twisting, where necessary, the main journal through 60 degrees.

The elimination of all sharp corners, as in keyways and the undercutting of webs in grinding journals and pins, was found to be of the utmost importance to prevent fatigue failure.

Rough machining before heat treatment was also required, especially in the rotary single-throw crank with large variations in mass of section, to secure uniformity of condition.

Cylinders.—In 1914 air-cooled cylinders were of mild steel for rotary and cast iron for stationary engines. The steel cylinders were machined from the solid billet; by 1916 forged blanks were used.

By 1915–6 cast-iron cylinders were cast from metal patterns and machine-moulded, and a close limitation of chemical composition adopted to secure clean casting of the thin sections, and to overcome distortion and cracking in running. To eliminate casting stresses cylinders were normalized after casting, and set aside for some weeks to " age " before machining.

For water-cooled engines having separate cylinders cast iron (with a sheet-steel jacket pressed to shape, and welded on, or a copper jacket electrically deposited) was used. To allow the jackets to expand, crinkles, both circumferential and round the exhaust valve seatings, and sparking-plug bosses were introduced, as the local expansion of the jacket differs from that of the cylinder when running.

Later, mild-steel cylinders turned from forged blanks were used in lieu of cast iron. Valve pockets, sparking-plug bosses, and thin sheet jackets were then welded on as first tried by Vickers in 1909.

Aero-engine cylinders are also cast together in one block for the sake of the rigidity of the cylinders one to another. At first, following motor-car practice, cast iron was used for this. Towards the end of 1916, however, aluminium, with its low weight and high heat con-

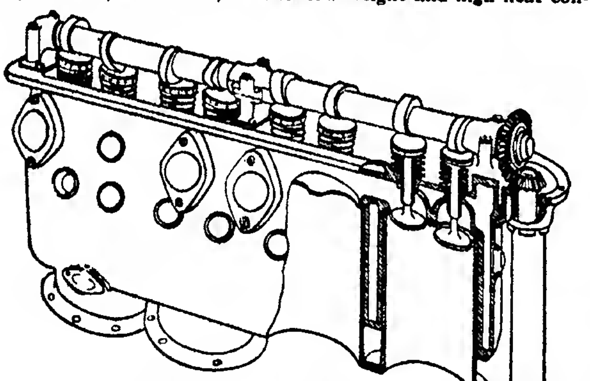

FIG. 20.

ductivity, took its place. The first prominent " Mono block " (see fig. 20) comprised a mild-steel cylinder liner complete with head and valve seats, screwed into an aluminium block which took four cylinders, and constituted a complete enclosed water-jacket. The liners were not in contact with the cooling water, and with bigger cylinders overheating and loss of contact between the liner and the surrounding aluminium jacket occurred particularly in the flat head. A natural development, therefore, was to remove the top of the liner, leave it open, and let the aluminium itself form the combustion head of each cylinder. Two difficulties then had to be overcome:—(1) The provision of a gas-tight joint between the top of the liner and the jacket and head; (2) the insertion of rings in the head to form valve seatings. The first was overcome by screwing the liner hard up against the shoulder in the head, and the second (which was achieved without distortion or burning of the seatings) by casting-in or expanding-in steel or hard bronze rings. To improve further the cooling of the cylinders, the lower portion of the aluminium jacket in contact with the liners was omitted, the liner being held only by a screw thread of some 1-in. depth at the top and a rubber joint and ordinary lock nut ring at the bottom.

The form of aluminium cylinder head and jacket casting is complicated, and experiments, both as regards method of casting and choice of aluminium alloy, led to the selection of a mixture of 12·5% to 14·5% zinc, 2·5% to 3·0% copper alloy with virgin aluminium. The pouring temperature is 660°C. The percentage of scrap is high, say, 10% to 15% in the simplest forms of block, and up to 30% or 40% for more complicated designs. To overcome the porosity of castings, stove enamelling of the interior of the blocks or the application of water-glass under pressure is used.

The Royal Aircraft Factory experiments in 1915 led the way in air-cooled stationary cylinder engines in the use of aluminium heads gilled for cooling, using a steel liner and inserted valve seatings. For rotary-engine cylinders in one instance a thin steel liner was shrunk into a finned aluminium shell which formed a jacket, the head of steel being secured to the liner with a plain metal-to-metal joint by bolts from the head to the crank-case, thus securing the cylinder as a whole.

Cylinders of all types before erection on engines are tested internally to 450–500 lb. hydraulic pressure, and for the jackets to 30–40 pounds.

Connecting Rods.—Connecting rods, as regards material, followed crank-shaft practice in the standardization of plain nickel chrome steel, heat-treated to give 50–60 tons' tensile strength.

The 6-cylinder and early 8- and 12-cylinder types conformed to motor-car practice in the use of solid " H " section shanks and white-metal big-ends, without a bronze bush, the cap being held usually by four bolts or studs. To reduce the crank-shaft length of certain " V " type engines the connecting-rods on one side of the engine were provided with lugs to carry a wrist-pin, this wrist-pin, on one side of, and parallel to, the big-end bearing, carrying the auxiliary connecting-rod. Alternatively to the same end a pair of rods superposed. In one case, a hollow circular sectioned shank carried an integral big-end, white-metalled internally and externally, the second rod, being fork-ended, oscillating on the sleeve formed by the first rod. The comparatively thin and flexible section of the inner rod sleeve, however, enhanced the difficulty of white-metalling and led to cracking in running.

A further development therefore (of square hollow sectioned shank) provided a bronze shell rigidly gripped by the forked ends of the outer rod, while the inner rod oscillates on the middle portion of the shell, which is white-metalled internally to provide the main big-end bearing, as shown in fig. 21.

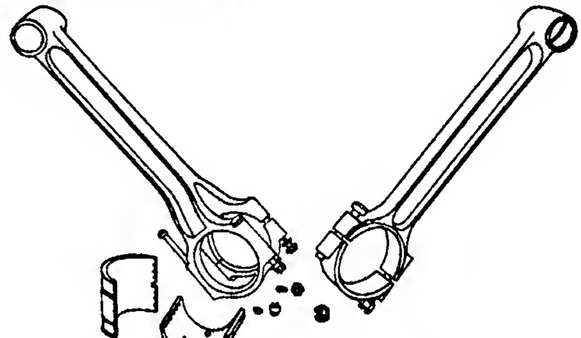

FIG. 21.

Connecting-rods of rotary and radial engines consist usually of one master rod, ball or roller-bearinged, with the big-end enlarged to form circular lugs to secure wrist-pins carrying the plain or auxiliary type of rod of the remaining cylinders. One exception provided a big-end consisting of a separate lead bronze shell (in two halves bolted together) mounted on ball bearings and provided on the inside with white-metalled concentric grooves in which oscillate the concentrically formed heels of the connecting rods.

Initially, the ordinary small-end bronze bush system with gudgeon pins fixed in the piston was used. Later, variations with loose bushes and loose gudgeon pins were developed, the pins in the latter being secured endwise in the piston by wire circlips let into grooves on the outside edges of the piston bosses.

Rough machining before heat treatment is necessary on the rotary type master-rod stamping which has a large big-end mass and a comparatively small stem section, to secure uniform structure and freedom from quenching cracks. The elimination of all sharp corners and abrupt changes of section is essential.

Main Bearings.—Ball, roller and white-metal bearings are to be found in various types. The two former permit of high loading and reduce the length of the engine (bearing loads approximating to 100% over normal practice being found to give a total life commensurate with the rest of the engine under service conditions). White-metal main bearings, usually bronze shelled, are secured either by separate loose caps bolted on or studded to the top half crank-case; or, as in usual German practice, by the bottom half crank-case itself, which carries the lower halves of the whole of the crank-shaft bearings; this adds to the rigidity and general strength of the engine, but increases the difficulty of production and fitting.

Valves.—Valve breakage, originally a trouble, was almost eliminated by the standardization of valve steels and by stamping the valves

so that the grain flow in the valve head swept continuously and uniformly from the rim into the throat and stem, thus providing strength to resist sheer at all points of the head. The original practice, before bulk production warranted the use of stampings, had been to turn valves from the solid bar, a procedure which gave in the head a grain flow parallel to the stem.

For exhaust valves a steel having 14% tungsten and 3·5% chromium is necessary in certain of the "hotter" stationary-type engines. For the cooler-running engines a high-chromium stainless steel gives satisfaction. Either of such steels would be satisfactory for inlet valves, but, for economy of such high-grade materials, a plain nickel steel is used with great success. (R. K. B.-W.)

V. Aero Engines

Historical Résumé.—For many years mechanical flight was delayed for want of a light engine, and indeed from the first flight to the present day (1921) the aeroplane was ahead of its prime mover. Flight should have been possible in 1901 when Manley, in the United States, built for S. P. Langley a five-cylinder radial petrol engine developing 52 H.P. and weighing only 2·9 lb. per H.P. By bad fortune this engine was, however, never used in flight until 1914, when it was mounted in the Langley aeroplane for which it was intended.

For their first flights in 1903, the brothers Wright built a four-cylinder car-type engine of 12 H.P. weighing 12·7 lb. per H.P. By 1905 it was improved to 19 H.P., with a weight of 9·5 lb. per H.P. and, as redesigned in 1908, gave 35 H.P. and weighed 5·5 lb. per H.P.

The aero engine proper dates from about 1909, and the progress made is traceable reliably by the results of competitive tests held from time to time. Such tests were carried out in France, 1909–11–13, in coöperation with La Ligue Nationale Aerienne and the Auto Club de France; in England in 1909–12–14; in Italy in 1913, and in Germany in 1912–4.

A certain section in England centred its hopes erroneously on the use of very small engines. A. V. Roe made the wonderful achievement of flying an aeroplane with only 9–10 H.P. in 1909. The Alexander prize of 1911 at first stipulated for engines of only 25 H.P. This was increased by the Advisory Committee at the request of the supt. of the Army Aircraft Factory to admit "40 to 75 H.P." and was won by 24 hours' continuous running by a 50–60 H.P. Green sent in on Sept. 11 1911. This engine weighed 296 lb. complete, and developed an average of 53·5 H.P. The British Government competition of 1914, although won by a 110 H.P. Green engine, was chiefly useful in showing the merits of the 100 H.P. Gnome and the 90 H.P. RAF. Both of these did yeoman service in the war, but soon proved to be too small.

In Germany, the development of the airship led to the earlier study of larger aero engines, although the German competition of 1914 was won by a 100 H.P. Benz, weighing 4·2 lb. per H.P. The importance of the aeroplane in war service gave an immense impetus to engine development along two main lines: (*a*) An extensive development of high tensile steels and aluminium alloys, and a more scientific use of the materials, led to a diminution of the weight; (*b*) attention to detailed design, guided by scientific investigation, greatly increased the mean effective pressure developed in the cylinders and the thermal efficiency. The speed of rotation was also increased so that output was augmented, while at the same time fuel consumption was reduced.

Modern aero engines may be divided into two classes:—(*a*) Engines which are developments of the motor-car type, *i.e.* all the water-cooled vertical, Vee, and broad-arrow engines; (*b*) types designed specially for aerial flight, *i.e.* the radial rotary engines and the air-cooled Vee engines.

The rotary air-cooled type, which was one of the earliest of these, was almost entirely due to the French; *e.g.* the Gnome, Le Rhone and Clerget engines. In this type minimum weight was the objective. The arrangement of the engine, with its cylinders radiating star fashion in one plane and operating on a single crank, afforded a crank-shaft and crank-case of minimum dimensions and accordingly gave a motor of extremely light weight. To increase the cooling by air draught, and save the weight of a fly-wheel, the cylinders were made to rotate round the crank-shaft, which was fixed. Weight was economized by making the cylinders of steel, with very thin walls, and the difficulties due to distortion of such thin cylinders with heat were ingeniously met by using a brass obturator ring, as substitute for the cast-iron piston rings which are universal in other engines.

In 1909 a number of rotary engines of powers ranging from 30 to 100 H.P. were available. Of these the 100 H.P. Gnome was the most powerful. In 1913 a 14-cylinder Gnome of 160 H.P. was launched, and on a British army aeroplane achieved the fastest flight up to that time, namely 130 m. per hour. At the outbreak of war in 1914, the 100 H.P. Monosoupape Gnome, and at a slightly later stage the 110 H.P. Clerget and the 100 H.P. Le Rhone came into current use, and the 160 H.P. Gnome was, unfortunately from the war fighter's point of view, discarded on the score of complication. In France in 1917 a higher-powered Monosoupape developing 150 H.P. was put into commission, while in Great Britain the BR1 and the BR2 rotaries, developing respectively 150 and 220 H.P., were produced. Including the propeller boss the later Mono-Gnome weighed 2·03 lb. per H.P. and the BR2 2·21 lb. per H.P.

In 1914, and indeed at a later stage, none of the rotary engines were quite satisfactory; the type suffers from certain inherent disadvantages. It is liable to the distortion and overheating of its cylinders; the earlier examples required special precautions against catching fire; its petrol and oil consumptions are high; and it requires frequent dismantling and overhauling.

In spite of this the best of these rotaries formed the basis on which European air experience was founded, and as recently as 1912 the best aero engines (from the point of view, be it understood, of the aeroplane's performance, which is dominantly a matter of weight) were probably the Gnome rotaries weighing from 3·0 to 3·5 lb. per H.P. At this time long-distance flights were exceptional and therefore their large fuel and oil consumption was not so serious. Throughout the war, and especially in its earlier stages, they gave their best service in machines of the single-seater high-speed class, in competition with the heavier water-cooled vertical engines on which the German air service relied almost entirely.

When the distance of flight was extended, the water-cooled car-type engine came to the front partly because the smaller weight of fuel to be carried compensated for the greater weight of the engine itself, and partly because it was at that time more reliable. The following table shows the total weights of engine, fuel and oil, for flights of different duration, in the case of a typical air-cooled rotary engine weighing 2·25 lb. per H.P. and consuming 1·10 lb. of fuel and oil per H.P. hour, and of a water-cooled engine weighing 4·0 lb. per H.P. and having a total consumption of 0·55 lb. per H.P. hour.

	Weight of engine, petrol, oil (lb. per hr.).					
Duration of flight (hrs.)	1	2	3	4	5	10
Rotary air-cooled engines	3·35	4·45	5·55	6·65	7·65	12·25
Water-cooled engines	4·55	5·10	5·65	6·20	6·75	9·55

For longer flights than 3½ hours the water-cooled engine is here shown to involve a smaller gross weight.

It was largely emulation of the rotary which forced the pace of the progress on the car-type engine. This led to the replacement of cast iron by sheet metal for water-jackets; to the use of thin steel instead of cast iron for cylinder barrels and of aluminium for cylinder-head castings; and to the use of two, and in some cases three, rows of cylinders operating on a single crank-shaft and mounted on a common crank-case. The use of steel or aluminium alloy instead of cast iron for the pistons had been initiated in experiments for motor-cars. In some few cases air-cooling was adopted, *e.g.* in France the 70 H.P. eight-cylinder Vee Renault of 1912, and notably in England the 90 H.P. eight-cylinder Vee RAF of 1913–4, and the 140 H.P. twelve-cylinder Vee RAF4a, all of which had cast-iron L-headed cylinders. The last-named engine weighed 4·0 lb. per H.P. and gave excellent service during the war.

Still the car engine of given cylinder capacity remained appreciably heavier than the contemporary rotary, until careful studies in 1916–17–18 were made to increase the output per unit of cylinder volume, and the thermal efficiency.

The volumetric efficiency was increased by improving the design of the inlet pipes, valves, and valve gearing, and the combustion space of the cylinder. The thermal efficiency and the mean effective pressure were increased by augmenting the compression. Since high compression is only practicable with a compact and symmetrical combustion chamber the L-headed cylinder was replaced by the overhead valve-cylinder. Moreover, since high compression necessitates good cooling of the cylinder, the water-cooled engine gained a distinct relative advantage over the earlier air-cooled engines which were, in general, inadequately cooled. As a result of these steps in the detail design, the brake mean effective pressure was raised from the 75 to 95 lb. usual on cars, to as high as 130 lb. per sq. in. in the best modern aero engines, while at the same time the petrol consumption was reduced to approximately 0·45 lb. per B.H.P. hour; a value some 40% better than that of the average car engine.

In many cases the output was also improved by increasing the speed of the engine. The speed of the rotary engine was limited to about 1,200 revolutions per minute, by the stresses due to centrifugal force. In the fixed cylinder engine, however, much higher rotational speeds could be adopted by attention to the balance of the moving parts, and to the design of the bearings. These speeds now range from 1,400 to 2,100 revolutions per minute, reduction gears being used for the airscrew drive in the case of the larger and less rapidly flying aeroplanes.

The resultant weight economy was considerable. Thus the 300 H.P. Hispano-Suiza water-cooled Vee, rotating at 2,000 r.p.m., weighed only 1·80 lb. per H.P. and the 450 H.P. Napier "Lion" of 1921 only 1·89 lb. per H.P. In each case these weights include that of the propeller boss, but not that of the radiator and its water, which would add approximately 0·55 lb. per H.P.

These advances in the car type of aero engine were accompanied by improvements in the specialized type. In 1912 the radial engine with fixed cylinders was represented by a few examples of which the 9-cylinder, water-cooled "Salmson" developing 110 H.P., the 6-cylinder, water-cooled "Laviator" developing 80 H.P., and the 6 and 10 cylinder, air-cooled "Anzani" developing 60 and 100 H.P. are among the most noteworthy. The Salmson was developed at a later stage as a 14-cylinder, two-row engine of 200 H.P. and the Anzani as a 20-cylinder, four-row engine of 200 H.P. These engines were French, but since 1914 British designers have greatly advanced the science of the air-cooled engine.

The fixed radial engine has a number of features of superiority over the rotary. It enables a normal type of carburetter and of piston to be used; it eliminates the large windage losses; while since the cylinders are not exposed to centrifugal stresses aluminium alloys can be used. This light and highly conducting metal has greatly helped air-cooling. Owing to the greater ease of installation of the air-cooled engine in an aeroplane, the absence of a fragile radiator liable to freeze on descent from great heights, as well as to its adaptability to work in the tropics, much attention was paid during the war to the design of air-cooled cylinders. A composite construction using aluminium alloy for cylinder heads was evolved at the Royal Aircraft Factory, Farnborough, between 1915 and 1921, with the result that air-cooled cylinders became available which, for diameters up to 6 in. and up to 50 B.H.P. per cylinder, give an output and fuel-consumption of similar order to those from the best water-cooled cylinders.

No air-cooled engine with these large cylinders reached the stage of production in quantity during the war. A number of British radial engines were, however, developed in 1918, and of these the "A.B.C. Dragonfly," having nine steel cylinders, giving 300 H.P. and weighing 2·22 lb. per H.P., and the 450 H.P. "Cosmos Jupiter," having nine steel cylinders with an aluminium patch containing the inlet and exhaust ports bolted to each head, and weighing 1·42 lb. per H.P., are worthy of mention.

As compared with these it will be recalled that the 150 Mono-Gnome of the same date weighed 2·03 lb. per H.P.

A 12-cylinder Vee experimental engine with aluminium cylinders was built at the Royal Aircraft Factory in 1916–7 and gave excellent results in flight and on the test bed. This developed 210 H.P. and weighed 3·0 lb. per H.P.

Prior to 1914 the American aero engine was mostly of the car type, and was outdistanced during the first two years of the war by the more intensive development in those countries actively engaged. At that time the 160 H.P. Curtiss was probably the most outstanding engine in America, and when the United States declared war in 1917 her need for high-powered aero engines became acute. In May 1917 it was decided, in conference with the Allied Mission in the United States, to design and build the Liberty engine, of which an 8-cylinder model was completed for test on July 3 1917. This was not put into production, as advices from France indicated that demands for increased power would render it obsolete before it could be produced in quantity. Efforts were then concentrated on a 12-cylinder model, the first of which passed its 50-hour test on Aug. 25 1917. This engine is a water-cooled Vee, originally developing 400 H.P. and weighing 2·0 lb. per H.P. More recent improvements have increased the output to 510 H.P. and reduced the dry weight per H.P. to 1·75 lb. or about 2·3 lb. with cooling water and radiator.

The progress in the average aero engine in service between 1910 and 1918, in power, weight, and efficiency, is shown in the following table. The main details are abstracted from the report of the American National Advisory Committee for Aeronautics in 1918:—

Engine	Date	H.P.	Weight lb.	Weight per H.P.	Average petrol (lb. per B.H.P.)
Average in service	1910	54	309	5·7 lb.	·72
" " "	1914	112	437	3·9 "	·65
" " "	1915	133	512	3·7 "	..
" " "	1916	185	570	3·1 "	·60
" " "	1917	234	603	2·8 "	..
" " "	1918	267	693	2·6 "	·55

Since the water-cooled engines cannot function without radiator and water, an addition of 0·55 lb. per H.P. has been made in their case to render Table A comparative. The weights after deduction of 0·55 lb. are actual measurements, and include those of the propeller boss and of the gear, if any. In cases where the respective makers produce a series of engines of different powers, only representative examples have been quoted.

During the latter part of the war, the demand for engines of large H.P. for bombing aeroplanes and dirigibles led to the production of many experimental engines, which were available by 1921, e.g. the 800–900 H.P. Sunbeam Coatalen, the 850 H.P. Fiat, the 1,000 H.P. Lorraine Dietrich, and the 1,000 H.P. Napier "Cub."

Types of Engines.—Of the total heat from the fuel, 25% to 35% passes through the walls and piston and must be dissipated by water-cooling or direct air-cooling if the normal operation of the engine is to be maintained.

Water or air-cooling have their respective advantages and disadvantages.

For the water-cooled engine is claimed:—

(1) A lower cylinder-wall temperature; a reduced tendency to the burning of exhaust valves and pistons; and more effective lubrication.

Table A.—*Details of the Principal Engines Available in 1918 for Service.*

Country	Engine	Type	H.P.	Weight	R.P.M.	Wt. per H.P.

(2) A greater uniformity of temperature throughout the cylinder, and therefore less tendency to distortion.

(3) Generally, greater reliability and higher efficiency.

These advantages could justly be claimed over the earlier types of air-cooled engines; to-day they are less clear. Thus the first claim is only justified where great attention is paid to the design and arrangement of the jackets and circulating systems. Measurements confirm claim (2), but also show that the lack of uniformity is not necessarily a serious matter, while troubles from overheated exhaust valves have recently been more prevalent on water-cooled than on the modern air-cooled type.

For the air-cooled engine is claimed:—

(1) Smaller weight per H.P. of the complete power unit.

(2) No danger of water freezing on gliding from great heights, or when standing.

(3) Reduced vulnerability in war service and easier installation.

(4) Special adaptability for use under widely differing atmospheric temperatures, and for the tropics.

(5) Better adaptability for application of some supercharging device to give constant power at heights.

Claim (1) is a matter of demonstration, the usual weight allowance for water-cooling being 0·6 lb. per H.P. while the very best is 0·4 lb. per H.P. Claim (2) is admissible to the extent that if freezing be prevented by the use of some other liquid, such as a mixture of alcohol and water, the alcohol evaporates unless the temperature of the fluid is kept below about 70° C. which increases the radiator size.

There is undoubtedly a future for the air-cooled engine of the fixed-cylinder type up to a certain size of cylinder. What this limit of size may be is not known at present. Cylinders of 8-in. bore by 10-in. stroke developing over 100 H.P. have been made and proved to be possible, and investigations on cylinders up to 10 in. in diameter are in progress. Twelve 6-inch cylinders would give 600 H.P., a useful size at present, and an 800 or 900 B.H.P. air-cooled engine is certainly feasible.

Design of Air-Cooled Cylinders.—The use of aluminium alloy for the cylinder heads has largely conduced to these results. In a normal design the middle portion of the head is the hottest point because the flow of cooling air and the placing of fins at this point is impeded by the inlet and the exhaust valve ports and valve gear. Most of the heat has to be conducted outwards till dissipated from the periphery of the combustion head, and the aluminium alloy effects this well, both because its conductivity is 3·5 times greater than the steel, and because being 0·4 of the density of steel it may be used in ample thickness.

Such a cylinder must be of composite construction, since the valve seats and the working surface of the cylinder barrel must be of some harder material than aluminium. The valve seats may consist of rings of steel or of bronze, and these may be either cast or expanded into position. Tests appear to favour a steel barrel with integral cooling fins, screwed into an aluminium head for diameters as large as eight inches.

Arrangement of Cylinders.—Aero engines may be subdivided according to the arrangement of their cylinders, into the following types:—

(1) Single line engines suitable for water-cooling.

(2) Vee engines suitable for water- or air-cooling.

(3) Broad arrow engines suitable for water-cooling.

(4) Radial engines—fixed cylinders; air-cooling.

(5) Rotary engines suitable for air-cooling.

The general arrangement of these types is shown in fig. 22.

The straight line engine (*a*), with six or eight cylinders in line, offers a low head resistance and is accessible. On the other hand its fore-and-aft length is large. The crank-shaft and crank-case are long, and hence the type is heavy.

In the *Vee type* engine (*b*) two lines of cylinders are used inclined to each other to form a Vee in elevation, and the corresponding port and starboard cylinders operate a common crank-pin. Weight is saved on crank-shaft, case, and valve gear.

In the *Broad Arrow* (*c*) three lines of cylinders are used as above with further weight saving.

In the *Radial engine* (*d*) economy of crank-shaft and case is carried to its logical conclusion. The cylinders are mounted in one plane at equal angular intervals around the crank-shaft. All the connecting rods operate on a single crank-pin. The small fore-and-aft length of the engine helps the aeroplane designer but its considerable diameter may hamper him.

To obtain explosion impulses at equal intervals throughout each revolution an odd number of cylinders must be used, the usual number being seven or nine. Where a larger power is required two rows of cylinders may be used, operating a two-throw crank-shaft. The radial cylinders may be stationary or rotating. In the latter case the airscrew is mounted on a continuation of the rotating crank-case. The rotating cylinder engine is quite unsuited for water-cooling. Although the radial engine with fixed cylinders is not well

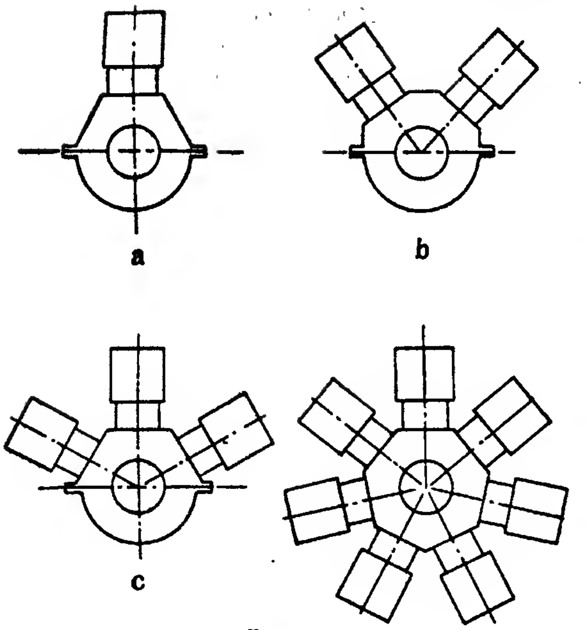

Fig. 22.

adapted for water-cooling, engines of this type have been built and operated successfully. Among these is the recent 300 H.P. 9-cylinder Fiat, weighing 1·7 lb. per H.P. The difficulty of arranging the water circulation so as to avoid all danger of air locks in the inverted cylinders is, however, appreciable, and the head resistance of the completed engine is large. For these reasons there is not likely to be any great future for the water-cooled radial engine on aeroplanes of present types.

Installations of Air-Cooled Engines.—Some form of cowling is needed to distribute the air evenly over the various cylinders, and the success of a Vee engine depends largely on the cowling, whereas even air-cooling is more easily obtained on a "radial."

With rotary engines the cooling is not as good as might be expected from the high peripheral velocity, and the windage losses, even with a cowling, amount to some 10% of the total power developed.

In these engines the air-petrol mixture is led through the hollow crank-shaft to the crank-case. In the original Gnome engine automatic inlet valves fixed in the piston heads and opened by the suction on the inlet stroke admitted the charge. These valves were light, often broke, and were inaccessible.

In the Monosoupape Gnome the valve in the piston is eliminated and a mechanically operated valve in the cylinder head is used. This serves as an exhaust valve, but, instead of closing at the end of the exhaust stroke, it remains open for a part of the inlet stroke and then admits air to the cylinder. When it closes, the further motion of the piston produces a partial vacuum in the cylinder, until, near the end of its stroke, the piston uncovers a ring of openings in the cylinder walls communicating with the crank-case. The fuel jet is adjusted to give a mixture too rich to be explosive, and this mixture enters into the cylinders and mixes with the air admitted through the inlet valve to form an explosive charge.

Other modern rotary engines have mechanically operated inlet and exhaust valves, with which efficient valve timing becomes possible. The mixture in the crank-case then passes into a circular box fixed to the rear of the crank-case and rotating with it, whence it is led by inlet pipes to the cylinders in the ordinary way.

These methods of mixture supply, though crude, gave the rotary engine the advantage of having a fuel supply adjustable by hand to suit the air density when flight at great heights first became important. On the other hand, the non-rotary engines, fitted with normal carburetters, received a mixture too rich for efficient operation at considerable heights. To obviate this, automatic carburetter controls had to be devised, but pending this the rotary engine had a distinct advantage for high flying.

The lubrication of the rotary engine is peculiar to the type. All oil in the crank-case is thrown centrifugally into the cylinders, and once there cannot be drained out, cooled, and circulated again as in fixed-cylinder engines, but must be discharged through the exhaust valves. Consequently the oil consumption is high. Moreover the lubricating oil must be insoluble in petrol, so that castor oil is necessary.

The power of the rotary engine falls off more rapidly with height than that of the fixed-cylinder engine if the latter has a suitably controlled carburetter, and at a height of 15,000 ft. the difference in horse-power is about 10 per cent.

The Differential Engine.—For large powers, each of the two types of radial engine has its own peculiar limitations. In the fixed radial the fly-wheel effect is small, while it becomes difficult to design an engine exceeding about 400 H.P. on a single crank because of the excessive load on the big-end of the connecting-rod. In the rotary radial this difficulty is less, but windage losses, centrifugal stresses, gyroscopic effects and valve-gear difficulties are encountered.

The "differential" engine has been proposed to combine some of the advantages of each type. Here the cylinder ring rotates in one direction and the crank-shaft in the opposite direction at the same speed. In this way the big-end loading may be kept within reasonable limits; the gyroscopic effect is negligible; centrifugal forces and windage losses are comparatively small; and the speed of rotation is low enough to permit an efficient airscrew to be fitted.

If the big-end loading be taken as the criterion, the power of the differential engine is about 30% greater than that of the fixed radial engine, or, deducting the windage loss, about 26 per cent. Whether this advantage outweighs the complication in design, remains to be proved.

Cycles of Operation.—All aero engines are of the single-acting type in which driving impulses are received on one side only of the piston, and in the majority of engines the four-stroke cycle is adopted. The two-stroke cycle has not hitherto been adapted successfully to the aero engine, owing to its comparative inefficiency in a high-speed engine which requires to operate over a wide range of speeds.

A six-stroke cycle is in the experimental stage. It consists of the four-stroke cycle with the addition of a suction and compression stroke. The first suction stroke draws in a charge which is compressed into an auxiliary reservoir on the succeeding stroke. The next stroke is also a suction stroke which draws in another fresh charge. At the end of this stroke a valve opens and admits to the cylinder the charge compressed during the preceding stroke, and during the succeeding stroke both charges are compressed into the clearance space and fired. In this way a charge of double weight is obtained and the mean effective pressure during the expansion stroke is twice as great as in the four-stroke cycle. The mean effective pressure over the whole six strokes of the cycle is thus 33% greater than the mean effective pressure over the whole four strokes of the ordinary cycle. Since the explosion pressures are approximately twice as great as in the four-stroke cycle the cylinder construction is heavier.

For evenness of turning moment, the two-stroke is better than the four-stroke, and this than the six-stroke cycle.

In each of these cycles the mixture is drawn into the cylinder, compressed, burnt at constant volume, and expanded to the same volume as before compression. The theoretical efficiency of this cycle is given by the expression $1-\left(\frac{1}{r}\right)^{\gamma-1}$ where r is the ratio of the volumes before and after compression and γ is the ratio of the specific heats of the working fluid at constant pressure and constant volume. This is known as the air standard efficiency. It assumes that the specific heat is constant at all temperatures, and that there is no loss of heat to the walls of the cylinder, in which case the value of γ is 1·408.

Taking into account the variation of specific heat with temperature, the appropriate value of γ in this expression becomes 1·295 and except for losses of heat to the cylinder walls and piston, the efficiency of an aero engine should attain the values corresponding to its compression ratio, which are:—

Compression ratio	4·0	4·5	5·0	5·5	6·0	6·5	7·0	7·5	8·0
$\eta = 1-\left(\frac{1}{r}\right)^{\gamma-1}$	·336	·359	·378	·396	·411	·424	·437	·449	·460

These figures indicate the importance of a high compression ratio. This is particularly important in the case of an aero engine, since the drop in power with height diminishes as the compression ratio is increased.

A limit is, however, set to the compression ratio in practice by the tendency of a petrol-air mixture to detonate when compressed to a high pressure and temperature. Such a mixture has a "spontaneous ignition" temperature corresponding to any definite pressure, at which it will detonate, and should this combination of temperature and pressure be attained in operation it is apt to cause overheating of the sparking plugs and to lead to general overheating of the cylinder and ultimately to pre-ignition.

The tendency to detonation depends largely on the design of the combustion chamber. It is less where this is compact and symmetrical than where it contains pockets as in a cylinder of the L-headed type. It also depends appreciably on the position of the sparking plugs, and on the composition of the fuel. The addition of benzol or benzene to petrol enables a higher compression ratio to be used, but owing to the comparatively high freezing-point of benzol, not more than about 25% can be used in admixture with petrol, for use at great heights.

By attention to design it is now found possible to use compression ratios as high as 5·5 when using petrol as a fuel, and as high as 6·5 when using petrol-benzol mixture. With such compression ratios,

fuel consumptions in the neighbourhood of 0·45 lb. per B.H.P. hour may be attained.

Supercharging for High Flying.—Since the power is proportional to the weight of petrol-air mixture taken in per cycle, and since this weight depends on the density of the surrounding atmosphere, the power falls off with the height reached. Tests show that in the average engine the power is sensibly proportional to the atmospheric pressure. The law of variation with atmospheric density varies slightly with the type of engine, but may be taken approximately as:—

B.H.P. is proportional to ρ^n where ρ is the density, and n varies from 1·1 to 1·3. increasing slightly with the height. At different heights the power developed by a 200-H.P. engine at a constant engine speed is thus approximately as follows:—

Height, feet	0	5,000	10,000	15,000	20,000	25,000	30,000
Density	1·0	·869	·714	·613	·527	·444	·360
B.H.P.	200	171	135	111	90	73	58
B.H.P. as % of ground B.H.P.	1·0	·855	·675	·552	·450	·365	·290

Since the resistance to the motion of an aeroplane diminishes directly as the air density, other things being unchanged, the level speed should only diminish slightly with an increase in height. This diminution in speed is, however, rendered more pronounced by the fact that the angle of incidence of the planes requires to be increased in order that they may support the same weight in air of reduced density, and this increases the head resistance.

The climbing speed of the aeroplane is reduced in a much greater degree, since the energy to be expanded in lifting the dead weight of the machine through a given height is independent of the density and remains constant at all heights; and at some definite height, depending on the design of the aeroplane and the power of the engine, the latter is only sufficient to overcome the head resistance when flying level at the minimum safe speed of the aeroplane with the increased angle of incidence of the planes, without leaving any surplus lifting capacity. This height is termed the "ceiling" of the plane.

Any device which would enable the power of the engine to be maintained at height would not only increase the level speed, but more especially the rate of climb and the height of the "ceiling."

Three such devices have shown promise. In the first the engine is fitted with differential pistons. Air is drawn into the space between these on the outward stroke of the engine, compressed on the return stroke, passed through a cooler, and forced into the cylinder through a series of ports uncovered by the piston slightly before the end of the suction stroke. By this method the weight of mixture in the cylinder is increased. The degree of "supercharging" may be adjusted by a regulating valve so as to keep the power constant over a range of heights up to about 10,000 feet. This scheme has not as yet been very successful owing mainly to mechanical defects.

In the second system a centrifugal blower is geared to the engine. The discharge from this is passed through the carburetter on its way to the cylinders which are thus fed with mixture under an increased pressure. The system is, of course, an added complication and involves the maintenance of very high-speed gears and bearings. As the induction system is under pressure, any leaky joints will derange the operation of the engine, and lastly, since the speed of the blower is constant at constant engine speeds, the amount of supercharging falls off with height, while, near the ground, air must be blown to waste through a bypass valve.

In the third system the engine exhaust is discharged through a single-wheel high-speed impulse turbine of the Rateau type. This turbine is direct coupled to a centrifugal blower feeding the carburetter, and delivers sufficient air to the engine to maintain its power at all heights up to about 15,000 feet. This method is partially automatic in that if the pressure in the induction pipe is maintained constant, the pressure of the exhaust gases will be constant, and since the pressure on the exhaust side of the turbine diminishes with height, the pressure available for driving the turbine increases with height to an extent which compensates for the increased demand for power by the blower. A valve for bypassing the whole or part of the exhaust gas directly into the atmosphere is provided to enable the output from the blower to be regulated.

Here also the induction system is under pressure. The weight complete for a 200-H.P. installation can be cut down to about 60 lb. and at 15,000 ft. the gain in power is about 80 H.P. for an expenditure of only 0·75 lb. per H.P. thus gained.

The increased complexity of the installation, the work thrown on the pilot, and the risk of breakdown will all retard the introduction of such schemes. Moreover, the additional weight may alternatively be devoted to increasing the size of the cylinders, leaving the crank-case and crank-shaft, etc., sensibly unaltered. Such a "light" engine would not withstand being opened out fully near the ground, and special precautions would require to be taken to prevent this happening. At height, however, it could be fully opened up, and the increased power corresponding to its increased cylinder diameter taken advantage of. Such a unit has the advantage of simplicity. Many of the latest and most powerful engines are really in a modified degree "light" engines, in that they cannot be run for more than a very few minutes "all out" near the ground.

Other methods of reducing the drop in power with height are possible. One such method is to design the engine with a compression ratio too high to permit of ground operation, and to reduce this near the ground by a cam giving a late closing to the inlet valve. As the height is increased the inlet valve would be closed earlier in the stroke until, at some predetermined height, normal timing would be attained. A second method which has been suggested consists in admitting a proportion of cooled exhaust gas to the cylinder with the working mixture. This reduces the tendency to detonation and enables a higher compression ratio to be adopted than would otherwise be possible. As the height increases the proportion of exhaust gas would be reduced, until, at the predetermined height, the engine would be working on a normal mixture.

Engine Starters.—The operation of starting an aeroplane engine by swinging the airscrew by hand has always been dangerous, and to remove the necessity for this, several types of self-starter have been devised. An electric motor geared to the crank-shaft through a clutch achieves this, but the number of starts possible with one charge is limited by the accumulator, and the weight and bulk of the installation restrict its sphere of usefulness. A compressed-air starter is lighter. Here a high-pressure cylinder supplies air to the correct cylinders by means of a distributor operated from the crank-shaft of the engine.

The most usual starting system consists of a supplementary magneto placed in the cockpit and rotated by hand by the pilot when the crank-shaft has been brought into the correct position. For success one or more of the cylinders must contain an explosive charge and therefore the crank-shaft is rotated slowly by hand, drawing a charge of petrol vapour from the carburetter as in normal operation. The plan is, however, unsatisfactory in cold weather, and starting is facilitated by admitting coal gas or hydrogen into the induction pipe from a small container, while the crank-shaft is being rotated.

One modern device, still (1921) in the experimental stage, consists of a small two-stroke single-cylinder engine which is started by hand and drives a compressor which draws an explosive mixture from its induction pipe and forces this through a distributor into the appropriate cylinders of the main engine. This charge is then fired in the usual way.

Future Development of the Aero Engine.—The development of the aero engine must increase its reliability, its useful life, its efficiency and its output in horse-power per unit weight, especially at height. Experience gained in the operation of existing types, by a process of survival of the fittest, slowly leads to the elimination of those details in design which are in the main responsible for breakdowns. The reduction of bearing loads and the improvement in bearings, increased perfection in balancing, better design of valve springs and of valve gears, of pistons and piston rings and of lubrication systems, will all add to the useful life, while improvements in carburation, in cooling and lubrication, induction systems, and in sparking plugs, will lead to increased reliability of operation. Efficiency will be enhanced mainly by such modifications in cylinder design or by the use of such fuels as will admit of higher compression pressures.

It seemed possible in 1921 that the Diesel cycle might be developed for aero-engine work, and the Junker engine of this type was said to have attained a fairly advanced stage of development in Germany. In view of the heavy cylinders required a sufficiently light Diesel engine, however, appears to be very difficult of attainment. Failing this, the direct injection of fuel into the cylinder during the suction stroke, using moderate compression ratios, may have possibilities. This is a modification of the method used in the early Antoinette engine, where fuel was injected by a pump into the inlet pipe of each cylinder. The method has the advantage of eliminating the carburetter and induction system and, in theory, of enabling a uniform mixture to be given to all the cylinders. Promising experiments on single-cylinder engines were in progress in 1921.

Outside existing designs in 1921 there appeared to be scope for an engine working on the two-stroke cycle, and for a double-acting line engine with cylinders in tandem. It is true that attention had already been paid to both these types without, as yet, successful results. Still, many of the initial difficulties had been surmounted, and there was every reason to hope that a successful design would ultimately be evolved. Such an engine would have excellent prospects of fulfilling the ideal conception of 1 lb. per B.H.P. which is at present the dream of the aero-engine designer. In view of the immense progress in the design of aero engines during 1911–21, it seemed probable that the aero engines of the future might well show as much improvement as those of 1921 did as compared with the machinery to which the early fliers entrusted their lives.

(A. H. Gi.)

VI. Air Navigation

Historical.—Navigation is the art of selecting the course which a craft should take in order to proceed from any one position on the waters to any other. For guidance in the building-up of air navigation centuries of experience of the sister art of

sea navigation may be drawn on, and much of this experience is capable of direct application to the air. The earlier forms of marine navigation were of a rudimentary type and would now be included in the general term "pilotage." Whenever they could manage to do so the primitive sea voyagers were careful to keep in sight of the coastline, so that even a rough map sufficed to enable the position of the ship to be noted. The great voyagers of the middle ages were bolder and depended no longer on mere pilotage methods; then it was that scientific navigation had its birth. The compass came into use in Europe about the 14th century, and by its means, combined with a rough measurement of the speed of the craft through the sea, it was possible to keep a reckoning on the chart—called a "dead reckoning," or briefly D.R.—of the position from day to day. This allowed nothing for drift due to tides or currents or leeway, but since in the early voyages these were quite unknown in amount no allowances could be made. Experience showed that the D.R. position thus obtained was often considerably in error, and some check upon it became very necessary. For this the simple cross-staff and the astrolabe were employed. With these instruments a rough measurement of the altitude of the sun at midday, or of the pole star at night, enabled the latitude to be determined to perhaps half a degree, or 30 nautical miles. But a simple latitude observation like this did not suffice to ascertain the ship's position, since it merely gave the information that it must lie somewhere on an east-west line drawn so many degrees N. or S. of the equator. If the course were N. or S., this measurement gave the run, but no check on the estimated course; whilst if the course were E. or W., the latitude measurement gave no information as to the run. Later on, when better instruments were available—the introduction of the Hadley sextant in 1731 marked a very real advance—methods were adopted to enable longitude as well as latitude to be measured, but the necessary calculation of lunar distances was troublesome, and it was not until the perfection of the marine chronometer in the latter half of the 18th century that it became open to the average sea navigator to work out his longitude as well as his latitude, and so obtain a check on both run and course.

Experience with air navigation has followed a generally similar path; compressed of course into a very few years. When air craft were first navigated they followed pilotage methods only; the earth was continuously, or almost continuously, in sight, and the position from time to time was ascertained by the recognition of landmarks, or, where these were scarce, by a system of dead reckoning based on the compass course and the speed through the air. Here, however, arises the great difference between sea and air conditions. Currents in the sea rarely exceed a few knots, but in the air are quite commonly of 20 knots, velocity, and may be even four or five times as much; moreover, whilst the former may be charted the latter cannot. This would tend to make air navigation the more difficult, but its effect is mitigated by the fact that the air ocean has the great merit—for this purpose—of being transparent (except for occasional cloud sheets) and of enabling the direction and course of air currents to be measured by watching the apparent motion of objects on the earth's surface. A wind of 50 knots opposing an aircraft having a speed through the air of 100 knots will reduce its speed over ground by one-half, while if favouring it will cause the ground speed to exceed the air speed by 50%: neither, however, will cause any apparent sideways drift of the craft. If, in either of these cases, the speed over the ground be measured in some convenient way, it is possible to determine both the velocity and direction of the air current, *i.e.* the wind. A similar but slightly more troublesome measurement gives the wind velocity, and direction, when the flight is oblique to the wind. This ability is not shared by the sea navigator, who cannot see the bottom of the ocean on which he sails, and has instead to assume the accuracy of the information given on his charts and in his sailing directions.

The fact that an aircraft, when flying with the wind, may have a ground speed of as much as 150 to 200 knots, makes it essential to determine the position with rapidity. An observation which took 10 minutes to reduce would afford information of a position some 30 nautical m. to the rear. Hence speedy methods are essential; and fortunately—owing to the absence of aerial rocks and shoals, and the extensive field of view—much less accuracy of position-finding is required in the air than at sea. An accuracy of determination of 10 m. suffices for almost all air purposes; whereas the sea navigator aims hopefully at an accuracy within a mile or less.

Dead Reckoning.—Hakluyt, recording in 1580 "instructions and notes very necessary and needful to be observed," points out that "in keeping your dead reckoning, it is necessary that you doe note at the ende of every foure glasses what way the shippe hath made (by your best proofes, to be used) and how her way hath beene through the water, considering withall for the sagge of the sea, to leewards, according as you shall finde it growe. Doe you diligently observe the latitude as often, and in as many places as you may possible; and also the variation of the compasse. . . ." These instructions, so necessary and needful to be observed at sea, are for air navigation not less so. But in the latter case special difficulties arise. The course over the ground is determined by the apparent motion of objects on the earth relative to the fore-and-aft line of the craft; but owing to the rolling, yawing and pitching of the latter, and of all instruments carried upon it, such measurements are far from simple. However straight the pilot may try to fly he will yaw slightly from side to side, and this will cause the flight path to be more or less sinusoidal, with an accompanying lateral acceleration tending to cause the machine itself, and all instruments fastened to it, to roll periodically to port or starboard. This will cause any objects below the craft to appear to follow an oscillatory path instead of a straight line, and so make the determination of the angle of drift much more difficult. Nor is it possible to surmount this obstacle by making the observing apparatus pendulous in the hope that it will remain vertical. The lateral acceleration due to the slightly curved path will cause the centre of gravity of the pendulous mass to seek a position such that the moments about the point of support of the weight will balance; in other words, the instrument tends to set itself not to the true vertical but to the "apparent vertical" given by the resultant of the gravitational and the lateral acceleration. If the pendulous instrument has a substantial amount of inertia, it will not have time to pick up this direction before the aircraft will have entered on a fresh part of its sinusoidal path corresponding to a fresh position of the apparent vertical. The instrument therefore continually hunts the apparent vertical, but is always in arrear to the one side or the other. It may appear that by making the inertia sufficiently great the motion of the instrument would be so slow and so slight as to be negligible, but calculation shows that unless gyrostatic forces, with their attendant complication, are brought into play it is not possible, within the necessary limits of dimensions of the craft, to achieve this. These ever-present oscillations are of great importance in the study of aircraft instruments. Not only is the apparatus for measuring the angle of drift of the ground affected by them, but equally any apparatus for getting a reading of the ground speed, and, by no means least, the magnetic compass itself. Compasses fitted to ships usually have a period of oscillation much longer than the period of roll of the ship, hence the compass has not time to be very much disturbed by such movements. In aeroplanes, however, the period of roll is longer and the early types of aircraft compass by an unlucky coincidence had just about the same period, hence resonance was a frequent occurrence, and wild oscillations of the compass needle were all too frequently reported. Later on the cause of the phenomenon was recognized and a remedy was found.

That a magnetic compass points magnetic N. instead of true N. gives rise to the correction called "variation," and this applies equally to sea and air craft. Variation charts are equally available and no difficulty is presented. With the correction known as "deviation" due to the magnetism residing in the structure of the craft itself, air conditions are simpler than those at sea, in that the masses of magnetic material near the compass position are much less in amount; but on the other hand the value of the deviation on each point of the compass is rather more troublesome to determine and much more likely to vary with the life history of the craft itself.

The measurement of the speed through the air fortunately presents none of these difficulties since the forces produced by the relative air stream are dependent only on velocity and air density, and the latter being known for any given altitude of flight it is possible to obtain a measure of velocity through the air free from any complication.

Except for flying-boats engaged on anti-submarine patrol scarcely any aircraft prior to the end of the World War had need to employ navigational methods of flight; ordinary pilotage sufficed for their journeys. The work of the flying-boat patrols, however, required meticulous care in navigation since their duties carried them far out of sight of land and it was imperative that they should make a landfall before the petrol supply ran out. The method employed was dead-reckoning navigation carried out with that care which the risk

of failure made necessary for all employed on this arduous service. That so few flying-boats were lost on such patrols says much for the care with which the instruments were attended to and the skill with which their indications were heeded. An error of only two degrees in the course made good would throw out the position by over 3 m. in each 100 flown: the consequences on a misty day for an aircraft trying to make, say, the Scilly Is. base can be imagined. There were then no facilities for astronomical navigation, and dead reckoning had to be relied upon.

Not only had the flying-boats on war service to be navigated but the pilot and observer had also to "navigate" a bomb to its desired target. Since a bomb, or any other heavy body, maintains the course and speed of its carrier aircraft substantially unaltered during its fall to sea level, the sighting problem is the same as the dead-reckoning navigation problem; in fact, one observing instrument can serve both purposes. The horizontal motion of the bomb is compounded of the wind velocity and the air speed of the craft. The distance it will travel horizontally will be the product of the resultant of these two velocities and the time taken to fall from the height at which the aircraft is operating. This then must be the horizontal distance of the craft from its target at the moment of release and the line of attack must of course be that of the course being made good. The angle ahead of the vertical which the target subtends at the moment of release is called the sighting angle, and obviously it will vary with the direction in which the target is attacked unless the wind velocity happens to be zero. This requires that the instrument should be set for height, air speed, wind velocity and wind direction, and further that it should make automatic provision for the right combination of these elements for any direction of attack.

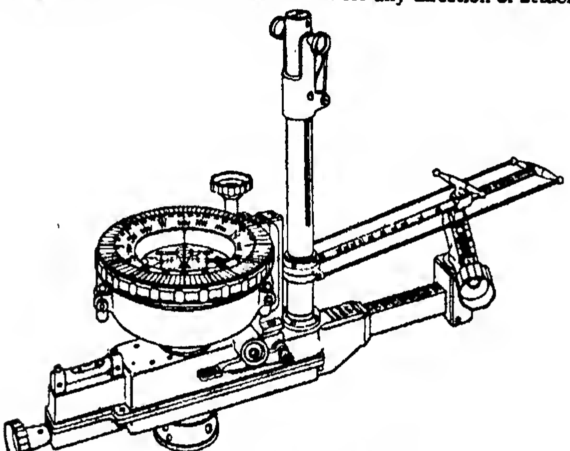

FIG. 23—Course-Setting Sight

The best known instrument for doing this is the course-setting sight shown in the illustration (fig. 23), and much used on flying-boats; in its navigational use it enables the velocity and direction of the wind to be measured whilst in flight, and it indicates the course to be steered for any given track, and the time taken in flying any desired distance in that direction. Towards the end of the war the French made some use of navigational bomb sights, and the United States Government had a large number constructed, but so far as is known no such efforts were made elsewhere.

For D.R. navigation on land aircraft use is often made of an instrument called an aero bearing plate. This was an adaptation of a marine bearing plate, or pelorus, having a transparent centre to admit of vertical observations of the ground, and having one or more longitudinal rods or wires which could be aligned parallel to the apparent earth flow so as to enable the drift angle to be read off. A graduated height bar also permitted the ground speed to be measured by noting the time taken for an object on the earth to pass through the vertical angle corresponding to a distance of flight of half a mile, or other convenient distance.

New Navigational Instruments.—One of the first instruments known to have been used for the determination of latitude in maritime navigation was the astrolabe. This device consisted of a pendulous disc graduated round its circumference in degrees and carrying at its centre a rod fitted with back and fore sights the inclination of which to the horizontal could be read off on the degree scale. A sight on a star would therefore give a measurement of its altitude. The use of a pendulum or "plumb bob" is, of course, a familiar way of obtaining a vertical line, but it suffers from the disadvantage that it no longer indicates truly if its point of attachment is not kept still. On board ship the point of support is necessarily in general motion and in consequence the pendulum continually oscillates: its average position still gives the vertical, but it is a tedious business to find what the average position really is. Seamen turned, therefore, to the visible horizon as a more satisfactory datum from which to measure the altitude of heavenly bodies; the early cross-staffs were inaccurate, but a nearly perfect form of instrument for this purpose was discovered in the Hadley sextant of 1731. It depended on the very important fact that if a beam of light be reflected from two plane mirrors in sequence, the total angle through which the beam is turned depends only upon the angle between the two mirrors and not on the angle between the rays of light and the mirrors themselves. Thus, if the two mirrors are fixed at an angle of 40° to one another, the angle through which the ray of light will be turned after the double reflexion will be exactly 80°; if this reflecting system be now used to view a star having an angular elevation above the visible horizon of 80° then the star will appear to be "brought down" to the horizon and its apparent position will not be affected, however much the frame carrying the two mirrors may be rocked in a vertical plane. It will easily be seen that for use on a rolling platform, such as the deck of a ship, this is a most valuable property. The seaman will see the horizon rising and falling relative to the ship, but the image of the star will rise and fall with it. If the two images only came into coincidence when the deck was level, the instrument would be useless. It is the fact that star image and horizon appear to move together when the ship rolls or pitches which makes the sextant the valuable instrument it is. Inasmuch as the pitching and rolling of an aircraft is sometimes just as bad as the pitching and rolling of a seacraft, it might be thought that the Hadley sextant would equally be of use in the air. Indeed, the instrument is equally available, but the horizon is not. At 10,000 ft. height the horizon is about 90 m. away, and unless the day is exceptionally clear there will be sufficient mist to prevent so distant a horizon being visible as a clear line. If the horizon has therefore to be abandoned as a datum line, it becomes necessary to fall back once more on the method of the mediaeval astrolabe and to employ plumb-bob methods of obtaining the vertical. This, of course, has the great disadvantage that it is only the average of a number of such observations that can give the true answer.

There is, however, a half-way house, though not a good one. Although the true horizon may be invisible there will often be false horizons given by the upper surface of cloud layers or banks of mist. These false horizons are not so far below the level of the aircraft as is the sea, hence their distance is much less and the line of separation between cloud level and sky is often sufficiently sharp to be of use. The great drawback is, however, the absence of definite knowledge of the height of such cloud levels, and therefore of their value as datum lines for sextant observations. A wrong guess at the height may give a totally false value to the sun's altitude, and therefore to the position line deduced from it. Attempts have been made to avoid such errors by assuming that the false horizon on the port side is of the same altitude as that to starboard, and then, by taking a point half-way in between as the zenith, to make all measurements from that as datum. This is correct just as often as the two horizons do happen to be of the same height; but it does not appear that this is always the case, nor in fact is a second horizon always visible, and at night time neither the one nor the other. Moreover, such level cloud or mist layers can only be expected when the temperature lapse rate is small and the air is very stable. On very many occasions these conditions do not hold, the air is frequently "bumpy," and the cloud masses heaped and tumbled. Speaking generally, the conditions in which large flat cloud sheets extend are conditions favourable to navigational measurements, and they are also the conditions in which accurate knowledge of position is most essential. Such conditions arise when the temperature falls but slowly with altitude. When this lapse rate (as it is called) is much lower than the 10° C. per km. which marks the condition of instability, there is little atmospheric turbulence, and the aircraft is comparatively steady; even a plumb-bob instrument is then a convenient method of making measurements. A spirit level is of course a form of plumb-bob, in that the bubble is a kind of inverted "bob," which tries to get as high up as possible instead of as low down. Such levels have long been used in inclinometers for surveying, witness the well-known "Abney level." They suffer, however, from the disadvantage that when the instrument rocks, the image and bubble move in opposite directions. No such device could be a success in the air, and it is necessary to incorporate the double reflexion method—or its equivalent—of the Hadley sextant. This has been done by the staff of the Royal Aircraft Establishment, Farnborough, in England, and by Prof. Wilson in America.

The principle of action of the R.A.E. instrument is shown in fig. 24. In this instrument—known as the R.A.E. bubble sextant—the vertical is given by the position of the bubble in a spherical level, capable of being illuminated at will by a little electric lamp. The eye may take up either position (1) or position (2). The former is best for star or planet observations, and the latter for those on the sun, though theoretically there is no reason why either position should not be used for all observations. It is a matter of convenience which is used; a star is more easily identified and held in view by the method of direct vision, whilst for observations of the sun there is no risk of confounding it with any other heavenly body, and it is much more comfortable to the eye to look downwards and so avoid the glare of the sky in the neighbourhood of the sun. The lens is chosen to have a focal length equal to its optical distance from the bubble, and since the curvature of the upper surface of the latter is

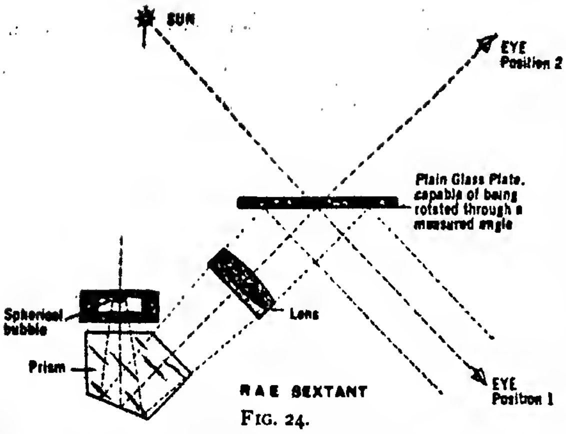

FIG. 24.

carefully chosen to be equal also to this distance, the bubble will remain in focus and will appear to move with the sun or star if the instrument should rock in the hand.

Gyrostatic Horizons.—When sextant observations are made at a ground station it is best to employ an artificial horizon, usually in the form of a bath of mercury. The sextant is then used to measure the angle between the heavenly body itself and its image seen in the reflecting surface of the mercury; half this angle is the angle of elevation of the body above the horizontal. Such a method is inapplicable to an aircraft for two reasons: first, that the vibration would cover the mercury surface with ripples and cause it to reflect a shimmer instead of a definite image; and secondly, that the acceleration forces would act on the mercury and cause its surface to tilt in one direction or another. For this reason use has sometimes been made of a little gyrostat spinning on a pivot and carrying a small circular mirror fixed at right angles to the axis of rotation. If this gyrostat accurately kept its axis vertical the little mirror would form a convenient substitute for the mercury bath. But it also is subject to the disturbing effect of acceleration forces, and is thereby deflected more or less from the desired position. Its behaviour in this respect is, however, much in advance of that of a simple pendulum or bubble; although since it is a rotating body it has the double disadvantage of requiring power to drive it, and of being adversely affected in its performance by the inevitable wear of its pivot. It is still uncertain whether a sextant using a bubble or a little gyrostat will in the long run prove the more suitable for air purposes. Gyrostatic means of measurement are, however, of much importance for air navigation, and the first application on a wide scale is that of the gyrostatic "turning indicator." In this device a gyrostat is spun in bearings so that its axis lies normally in a horizontal plane. If then the framework containing the bearings is turned about a vertical axis—due to the aircraft carrying it turning to port or starboard—the gyrostat will tend to turn itself about an axis perpendicular alike to that about which the forced turn occurs, and that about which the gyrostat is itself rotating. This effect is called "precession" and the couple brought into play is called the "precessional couple"; this couple is caused either to compress or to wind up a spring and in so doing to move a pointer, the indications of which give a measure of the degree of rapidity of the turn, and whether the direction is to port or starboard. Such turning indicators are invaluable when flying in cloud, mist or fog. Without them a pilot tends to lose all sense of direction, and the indications of the compass, which might be thought a sufficient safeguard against such uncertainty, are in some cases so affected by the large and sudden acceleration forces brought into play as to be quite misleading in their indications. The reason for this will be dealt with at greater length in what follows. The gyro turning indicator was first employed for measuring the rate of roll of ships (apparatus for this purpose was made both by J. B. Henderson and H. E. Wimperis prior to the World War) and its use on aircraft came in the later stages of the war. In the meantime an aircraft turning indicator due to H. Darwin had been employed; this depended on the static air pressure at the two wing tips being communicated to a differential manometer (air-speed indicator type) and a reading being given whenever the aircraft turned, since in so doing it introduced centrifugal forces which disturbed the balance of the two pressures and so gave a plus or minus deflection of the manometer needle. The instrument works well, but needs more attention than the gyro device.

Gyrostats are also used in aircraft as azimuth indicators for experimental or test purposes; they may some day be used as part of a gyrostatic compass, but the necessary weight limit will make their introduction for this purpose a matter of some difficulty.

Magnetic Compass.—The design of the magnetic compass as applied to aircraft has in late years undergone a marked improvement. Quite early tests showed that the compass should be a liquid one, and that—to avoid the effect of engine vibrations—the pivot should be above the cup. But most of the early compasses had periodic times of oscillation about equal to those of the airplanes on which they were carried, and resonance in vibration took place, so that when the airplane rolled even a little, the compasses oscillated through considerable angles. Moreover, such short compasses gave false readings of a turn when flying on any course between N.E. and N.W. The simplest explanation of this phenomenon (first given by Keith Lucas at the Royal Aircraft Factory in 1915) is that since in these latitudes the north-seeking end of a balanced magnetic needle tends to dip downwards it is customary to add a weight to the south end in order to keep the compass card horizontal. When an airplane flying N. begins to turn to starboard this little weight is acted upon by a centrifugal force acting from E. to W. and hence tends to turn the compass card also to starboard. An ideal compass would remain pointing exactly N., and the turn of the aircraft to starboard would be noticed by the apparent motion of the lubber mark from N. towards E. around the compass card; but if the card is also rotating in the same direction, and at perhaps a greater angular speed than the airplane, the lubber mark may appear to move towards the W., giving the false impression of a turn to *port*. Hence a flier unable to see the ground may infer quite wrongly that he is turning to port when he is really turning to starboard. In order, as he thinks to correct his turn, he tends still *more* to starboard whereas he really should have turned to port. The compass therefore fails to keep him on a straight course. Many of the earlier types of compass had this defect, but by making the compass period very much longer (as suggested by Keith Lucas), or by making the damping friction very much greater (as suggested later by Campbell & Bennett), the northerly turning error was either eliminated or greatly reduced. There is, however, a practical limit to the length of the periodic time, since if this be too great it becomes difficult to use the compass for ordinary navigation: it is too sluggish in giving its indications. This limit also concerns the highly damped—or aperiodic—compass, but not in the same degree. It is easier to construct a good compass by making the degree of damping approach the aperiodic than in any other way. Theory indicates that the performance of compasses is governed more by the product of undamped periodic time and the damping coefficient than by any other equally simple factor. In the early types of compass both elements entering into the product were too low; this was remedied by Keith Lucas in the one direction and by Campbell & Bennett in the other. Actually it is best to use both means subject always to the limit of not making the compass too slow in its movements.

Air Speed and Height Measurements.—The measurements of air speed and height are linked together, since both depend on the temperature, pressure and density of the air. The usual form of air-speed indicator, first made by M. O'Gorman in 1911, makes use of the difference in the air pressure in two tubes, one of which has an open end facing the direction of motion, and the other a closed end, but with a hole in the side. In the latter the static pressure is read, and in the former the larger pressure due to the addition to the static of the kinetic effect of the air speed. A simple instance of a similar effect is seen when a plank is dipped vertically into a flowing stream; the surface facing up-stream will be wetted higher up than the one facing down-stream. The difference in height is a measure of the velocity—or rather of the square of the velocity—of the stream. In the case of a compressible fluid like air it also depends on its density. In fact, the reading of the air-speed indicator is proportional to the product of the density of the air, by the square of the velocity through the air. Since such instruments are always calibrated so as to read correctly at sea level, it follows that the "indicated" air speed will always be less than the true air speed at altitude. Thus an aeroplane travelling at 140 m. an hour at a height of, say, 21,000 ft. will only be credited with 100 m.p.h. on the air-speed indicator. Such indicators are therefore sometimes provided with circular calculators around their circumferences to enable the true air speed to be read for navigational purposes. For aerodynamic purposes such corrections are quite unnecessary since the forces due to air pressure acting on the wings, the fins, the tail and all other surfaces will also be proportional to the product of air density by the square of the speed, and an instrument like the air-speed indicator which gives a reading proportional to this product is, for this purpose, ideal and needs no correction. So that, although for purely navigational requirements it might be thought advisable to introduce a type of air-speed indicator giving true air speed, such action would be disadvantageous from the purely flying point of view. Hence it is best to retain the present instrument and to add for navigational purposes a circular calculator to effect the conversion. The case of the aneroid is not entirely parallel, but it also needs a supplementary device if the true height is to be read. Almost all altimeters in use are based on the pre-flight aneroid in which the trade convention was to assume everywhere an atmospheric temperature of 10° C. Although this is not widely out for the average surface temperature it is manifestly most incorrect at a height, since on the average the temperature falls by about 6° C. for every km. (3,281 ft.) of ascent. Thus at 7 km. (23,000 ft.) the *mean* temperature of the atmosphere would be about 21° below the assumed steady level of 10° C.; a difference of about 7%, leading to an over-estimate of height by the same amount. This is corrected by reading the temperature at height on a strut thermometer and using a circular calculator (the A.M.L. height computer)—as in the case of the air-speed indicator—

to give the true result. For surveying work an accurate measure of the height is of special importance.

Reduction of Astronomical Observations.—The traditional method of maritime navigation is to employ logarithmic tables for the solution of the spherical triangle. The problem is: given the declination of the heavenly body, the latitude of the assumed position and the hour angle at the moment of observation, to determine the corresponding altitude of the heavenly body. The difference between the altitude thus calculated and the corresponding value as measured with a sextant gives the "intercept," and the azimuth its bearing; this suffices to enable the "position line" to be drawn in the usual way.

To make this calculation by means of logarithmic tables is simple enough on board an airship, but is not easily performed in an aeroplane. Nor is the degree of accuracy to which the existing tables are worked out necessary for air navigation. A method, which was tried in a Handley Page machine, was to use the rectangular nomogram devised by d'Ocagne, but it was found that within the limits of space available it was not possible to draw the diagram to a sufficiently large scale to ensure the final answer being accurate within the necessary one or two minutes of arc. (It is true that the determination of position to within 10 m. easily suffices, but there is not infrequently an error of this amount in the sextant observations themselves; and to these unavoidable errors of observation it is not desired to add any larger error due to the process of reduction of more than one or two miles.) Trial was next made of the ingenious method suggested by Veater of employing a Mercator projection of the sphere and using certain curves drawn thereon to solve the spherical triangle by the equivalent of a rotation of the sphere. This method gave, in small compass, a means of attaining the accuracy desired; but it was difficult to use the curves without eye strain, and the method eventually gave place to the cylindrical slide rule devised by L. C. Bygrave. The whole procedure is by this last means made both simple and accurate. The advantage of the spiral scale of cylindrical rules is that an immense length of scale is compactly housed; an accuracy on this rule of one or two minutes of arc is easily attained.

Directional Wireless.—During recent years wireless telegraphy has been made use of for the determination of the position of both sea-craft and aircraft. The invention followed from the discovery of a method by which the direction from which wireless waves were arriving could be accurately measured. An analogy would be afforded were it possible to determine, from the receipt of ripples at the margin of a pond, the direction of the spot at which a stone had fallen into the water. It was found that if a rectangular coil happened to be placed so as to face the direction from which the wireless waves were travelling, no current would flow in the coil, whilst if the latter were placed "edge on," it was possible to detect an oscillating current in the coil. In intermediate positions, intermediate results were obtained. Once, therefore, a search coil of this kind is mounted on a vertical axis it can be turned until the current is either a maximum or a minimum, and by these means the direction of the sending station be determined. It is true that a station N.E., say, could not be distinguished from one to the S.W., but other considerations usually enable a right choice to be made from these two alternatives. In practice various electrical improvements have been made on this simple circuit but the principle is the same; and it is the results obtained by such means which are of importance to the navigator. The navigator will of course require of the wireless officer that W/T bearings so given shall be "true," and that corrections due to any possible bending of the waves shall have been allowed for.

There are two methods by which "directional wireless" (as it is termed) can be employed. The first and simplest is by having suitable search coils mounted in wireless beacons ashore. Two or more of such beacons take note of the direction of the calling aircraft, and communicate with each other so that one of them can plot on a map the several bearings which, by their common point of intersection, determine the position. This is then communicated to the aircraft. This plan has the double disadvantage that the aircraft is forced to disclose its position, and that the number of messages sent out "into the air" is thereby increased. The alternative is to mount the search coil on the aircraft, and for the latter to determine the bearings of two or more sending stations, and to do its own position-plotting on the chart. The latter alternative is usually preferred, but it suffers from the difficulty that the bearing of the wave is not infrequently altered immediately prior to receipt by the influence of the many flying, and other, wires forming part of the structure of the aircraft. These are called quadrantal errors, and they correspond to the errors which would be obtained in magnetic compasses if deviation were not allowed for. A difficulty common to both methods lies in the bending of the ray's direction when crossing a coast line, or the boundary of day and night—such effects need to be allowed for. The plotting of wireless bearings, whether in the aircraft or ashore, requires care. If, as is usual, a Mercator chart is employed, it has to be borne in mind that straight lines on such charts are not great circles, and since the waves travel along the latter (except for the disturbances above mentioned) it is necessary to draw the path of the waves by means of a certain curve, the bending of which will depend on its distance from the equator. Approximate methods of doing this are in use, but the best method (following Veater) is to make use of the Littrow projection of the sphere (more familiarly known as the "Weir diagram").

Much work has still to be done before it can be determined how accurately the position of an aircraft can be found by means of directional wireless. But it has a great use apart from position finding, since it enables a straying aircraft to fly back to its parent ship by flying "home" along the wave path. Its path may not be a straight line, and it may take some time to make the flight, but if persisted in it is bound to bring the craft home sooner or later.

World Flights.—The famous world flights of 1919 and 1920 were the transatlantic crossings by the American flying-boat NC4, by the Vickers-Vimy aeroplane, and the rigid airship R34 (not forgetting the gallant attempt of the Sopwith aeroplane); the flight to Australia by a Vickers-Vimy aeroplane, and the several attempts to fly an aeroplane down the length of Africa.

In the case of the Australia flight the coast line was usually followed and methods of air pilotage, as distinct from air navigation, sufficed. The African flights were in part over uncharted territory, and pilotage alone did not suffice; both there and, of course, in the transatlantic flights the course was steered by navigational methods. In the case of the R34 the operations were carried out by officers accustomed to the navigation of naval ships, and in so roomy a craft the work was much more easily arranged than in the more compact aeroplanes and flying-boats. Comm. Mackenzie Grieve, the navigator of the Sopwith, stated that even in his tiny aeroplane he navigated by celestial observations and found that his position, as given by his observations of the stars, when picked up after the forced landing in the sea was "practically correct."

The instruments available in 1921 for navigation were much more satisfactory than those in use prior to 1920. In future world flights the determination of position, course and speed will not only be simpler and more speedy, but will also be very much more accurate than anything hitherto known in the history of air navigation.

VII. Control of Air Traffic

The pre-war legislation of individual States generally presumed sovereignty of the air, but the doctrine was not finally accepted until the World War. Thus in 1911, at the Madrid session of the Institute of International Law, a resolution was passed that "International aerial circulation is free, subject to the right of States to take certain steps, which shall be fixed, to ensure their security and that of the persons and property of their inhabitants." This principle was modified in the Report of the Committee on Aviation of the International Law Association in 1913:—

> "It appears to the Committee impossible to contend that according to existing International law the air space is free; nor do they think that States would be willing to accept or to act on that view of the law. But they are of the opinion that, subject to such safeguards as subjacent States may think it right to impose, aerial navigation should be permitted as a matter of comity."

Though in some quarters the assertion of state sovereignty only up to some prescribed height was advocated, individual States, and among them Great Britain, asserted, mainly for military reasons, their right to close their atmosphere absolutely (*usque ad coelum*) to the aircraft of other States. It was the conflict of opinion between the British and German delegates, as to the right of each State to the exercise of control and jurisdiction in the air space over its territories, that prevented the completion of an International Convention by the conference held in Paris in 1910. By the first British Aerial Navigation Act (1911) power was taken to prohibit the navigation of aircraft over prescribed areas. In the Act of 1913 this power was extended for the purposes of the defence or safety of the realm to the whole or any part of the coastline of the United Kingdom and territorial waters, while the Statutory Rules and Orders of that year limited the landing areas for aircraft coming from any place outside the United Kingdom to a comparatively few strips of coastline, and forbade foreign naval or military aircraft to pass over or land within any part of the United Kingdom except

with express permission. By a French decree of 1913 the circulation in France of foreign military aircraft was forbidden, and the draft Franco-German Agreement of 1913 practically admitted the principle of the sovereignty of the air by allowing each country the right of making such regulations as it pleased for flights above its own territory.

From the beginning, therefore, air sovereignty and air legislation were influenced by a predominantly military conception of aviation, and, on the outbreak of war, the doctrine of the freedom of the air was doomed. In the words of the Civil Aerial Transport Committee in 1918: "Since the outbreak of the war sovereignty over the air has been generally claimed and, except by Germany, recognized." During the war neutral countries consistently regarded the passage of belligerent aircraft over their territory as an unneutral act.

Pre-war legislation was in spirit and effect distinctly national, and in Great Britain regulations affecting the entry of foreign aircraft from abroad were stringent. In the case of airships a clearance from a British consular officer was required, and in the case of aeroplanes notice had to be sent to the Home Office giving the proposed place of landing, time of arrival, and nationality. Aircraft were forbidden to carry mails or goods chargeable upon importation, and before departure were obliged to report to an officer at one of the prescribed landing-places. Otherwise, with the exception of an Order prohibiting the navigation of aeroplanes within four m. of Charing Cross and of a number of small areas over which flying was prohibited on military grounds, there was no State regulation of flying, and certification and other safety measures were carried out by the Royal Aero Club, which represents Britain on the Fédération Aéronautique Internationale.

A similar state of things existed in France until the passage of the Aerial Navigation Act of 1913, which was to a considerable extent based on the draft Convention of 1910, and made the owner of an aircraft responsible for damage to property, provided for the registration, marking and inspection of aircraft, pilots' certificates and log books, and prohibited the transport of foreign merchandise or of national merchandise unaccompanied by papers testifying to its French origin.

The only serious attempt to place aviation on an international civil basis, by the adoption of a code of regulations common to all countries, was the draft Convention of 1910, which dealt with the nationality and registration of aircraft, certificates and licences, the admission of aerial navigation over the territory of foreign States, customs and transportation, and rules of the air. The international aspect of aviation did not, however, completely die with the failure of the Convention to materialize. The Institute of International Law, in its session of 1911, adopted rules distinguishing aircraft as public and private, confining an aircraft to one nationality, *i.e.* that of the country in which it was registered, and imposing identification marks. Another step in international air traffic was the Franco-German Agreement of 1913 permitting the entry of civil aircraft into each country subject to the conditions that machines were provided with navigation licences and distinctive identification marks, that the fliers were provided with proficiency and nationality certificates, and that the requirements of international law and the customs and air regulations of each country were observed.

In England in 1913 the Convention of 1910 was reconsidered by a sub-committee of the Committee of Imperial Defence; and when the advance in flying during the war indicated the great potentialities of aircraft for civil transport, a Civil Aerial Transport Committee under the chairmanship of Lord Northcliffe was appointed by the Air Board in 1917 to consider the whole subject, both from its international and national aspects. It was not, however, until after the Armistice that the first steps were taken by a departmental committee of the Air Ministry to frame regulations for civil flying in Great Britain. Shortly after, the drafting of a Convention governing international civil flying was included in the work of the Peace Delegates at Paris—the coördination of the British proposals therewith being undertaken by Sir Frederick Sykes, and took shape as the International Air Convention, which was signed by the majority of the Allied and Associated Powers on Oct. 13 1919, though up to Aug. 1921 ratification was not yet complete.

The objects aimed at by the Convention are the encouragement of the peaceful intercourse of nations by means of air intercommunication, and the establishment of a broad basis upon which a uniform procedure for the control of air traffic can be drawn up by the contracting States.

The parties to the Convention recognize the exclusive sovereignty of every Power over the air space above its own territory and territorial waters and those of its colonies, and while each contracting State allows freedom of innocent passage above its territory, except over certain areas prohibited for military reasons, to the aircraft of other contracting States, it may not, except by a special temporary authorization, permit the flight above its territory of aircraft belonging to non-contracting States (Article 5).

Every aircraft of a contracting State has the right to cross the air space of another State without landing, subject to following the route fixed by the State, but if it passes from one State into another it must land, if required to do so by the regulations, at an appointed aerodrome. Every State has the right to establish reservations and restrictions in favour of its national aircraft in connexion with the carriage of persons and goods for hire between two points in its territory but is liable to reciprocity on the part of other States. Any aerodrome in a contracting State open, on payment of charges, to public use by its national aircraft, is likewise open to the aircraft of all the other contracting States.

Aircraft engaged in international navigation must be provided by the State whose nationality it possesses with certificates of registration and airworthiness, certificates of competency and licences for the crew, which must be recognized as valid by the other States, a list of passengers, and, if freight is carried, bills of lading, log books and a special licence for any wireless equipment carried.

The Convention forbids the carriage by aircraft, engaged in international navigation, of explosives, arms and munitions of war. All private aircraft, *i.e.* aircraft which are not used for military purposes, or employed exclusively in State service, are subject to the provisions of the Convention.

A series of annexes to the Convention give detailed regulations with regard to the marking of aircraft (Annex A), certificates of airworthiness (Annex B), log books (Annex C), lights and signals and rules of the air (Annex D), pilots' and navigators' certificates (Annex E), maps and ground markings (Annex F), the collection and dissemination of meteorological information (Annex G) and customs (Annex H).

The Convention provides for the establishment of a permanent International Commission of Air Navigation, affiliated to the League of Nations, consisting of two representatives of the United States, France, Italy and Japan, one representative of Great Britain and each of the British Dominions and India, which are deemed States for the purposes of the Convention, and one representative of each of the other contracting States, for carrying out the terms of the Convention and the interchange of information.

Disagreements among States as to the interpretation of the Convention and technical regulations are to be settled respectively by the Permanent Court of International Justice and a majority of votes of the Commission. A State which took part in the war of 1914–9 but which is not a signatory of the Convention may only adhere to it if a member of the League of Nations, or, until Jan. 1 1923, if its adhesion is approved by the Allied and Associated Powers, or after that date if it is agreed to by at least three-fourths of the signatory States.

States which remained neutral during the war have not availed themselves of the Article permitting their adhesion to the Convention, mainly owing to the restriction placed by Article 5 on their intercourse by air with late enemy States. To overcome this difficulty, a Protocol was subsequently added to the Convention permitting certain derogations to Article 5 and authorizing the contracting States profiting thereby to allow, for a limited period of time, the aircraft of one or more named non-contracting States to fly over its territory.

The above Convention of 1919, the charter of international flying, may be regarded as prescribing the minimum control required from contracting States. There is no reason why States should not make their regulations more stringent for their own aircraft in the interests of safety and efficiency. The harmonization of the regulations enforced by the contracting States will undoubtedly form an important part of the functions of the International Commission of Air Navigation.

During 1919–20 a large number of countries, including, among others, Great Britain, France, Belgium, Spain, the Scandinavian kingdoms, Holland, Italy, Switzerland and Germany, passed regulations more or less in accordance with the requirements of the Convention, though in most cases frequent additional Acts or Decrees, embodying modifications in the original regulations, have been found necessary to secure stricter conformity with the Convention. Thus the British Aerial Navigation Act of 1919, and the Regulations issued by its authority which were influenced by, but actually preceded, the signature of the Convention were only temporary, and were superseded by the Air Navigation Act of 1920.

The Act of 1920 asserts absolute sovereignty over all parts of His Majesty's dominions and adjacent waters, provides for the application of the Convention by Order in Council to internal flying, the regulation of civil flying and the supplementing of the Convention, as necessary, by general safety regulations. It authorizes any steps to be taken for preventing aircraft from flying over prohibited areas or entering the British Isles in contravention of the law, and permits the extension of the provisions of the Act to British Possessions other than the Dominions and India. The Act also provides for the prohibition of all flying, and the taking over of aircraft, etc., in time of emergency; the establishment and maintenance of aerodromes by the Air Council or local authorities; purchase of land; compulsory investigation of accidents; and penalties for dangerous flying. No action lies in respect of trespass or nuisance by reason of the flight of aircraft over any property at a reasonable height above the ground, or the ordinary incidents of such flight, so long as the provisions of the Act and Orders made thereunder are complied with, but where damage is caused by aircraft, damages may be recovered from the owners of the aircraft. The law relating to wreck and salvage at sea applies to aircraft in the same way as to vessels.

Administration.—The methods of administration adopted in Great Britain in conformity with the Air Navigation Acts were probably, in 1921, in advance of those in other countries, but they might be regarded as typical of what would be required, at least in the near future, before aircraft could be operated by companies or private individuals in accordance with the terms of the International Air Convention. Their essential points are given below.

(i) *Registration of Aircraft.*—Every aircraft must possess a certificate of registration, which lapses on change of ownership.

(ii) *Licensing of Personnel.*—For a private pilot's licence the Royal Aero Club certificate is accepted as a certificate of competency, the Club having agreed to bring their tests for this certificate into line with those laid down in the International Air Convention. A person qualified as an R.A.F. pilot is entitled to a private pilot's licence. For a licence to fly a passenger or goods aircraft for hire or reward an applicant must undergo a medical examination, pass certain practical flying tests and a technical examination, submit proof of reasonable flying experience within the previous six months on the class of machine for which a licence is required, and pass an examination in navigation and elementary meteorology. In the case of applicants who are qualified as R.A.F. pilots the tests are limited to an examination in navigation and meteorology. Licences are issued for six months. There are five grades of licences for navigators. Aerial navigators, fourth-class, are licensed only to navigate civil aircraft over land by day, those qualified for the third-class certificate are licensed to navigate only over land by day or night, whilst those attaining the higher classes are licensed to navigate over both land and sea by day or night. Licences for ground engineers, usually valid for twelve months, are granted for the inspection and maintenance or overhaul of aircraft or engines.

(iii) *Airworthiness.*—In order that an aircraft may receive a certificate of airworthiness, its design, including the design of its components, must be approved as satisfying the requirements of safety in regard to both strength and stability; it must be constructed of approved materials and by workmanship of approved quality, and its engine must be approved.

In order that such certificate may be valid on any particular occasion the aircraft must be examined before flight and be periodically overhauled by a competent person duly licensed; it must be so loaded that its total weight does not exceed a given maximum, and its centre of gravity must be situated within certain given limits. If the application for a certificate is in respect of a "type" aircraft, inspection is carried out by representatives of the Aeronautical Inspection Directorate, and, in addition, such drawings and particulars are required to be furnished to the Director of Research, as will enable him to approve the design. In the case of "subsequent" aircraft constructed by a firm whose inspection is approved, sole responsibility lies with the Aeronautical Research Directorate, the constructor insuring that the conditions governing the inspection of "type" aircraft are applied to "subsequent" aircraft. A certificate of airworthiness is not valid unless the aircraft concerned is regularly inspected by a licensed ground engineer employed by the owner of the machine.

(iv) *Aerodrome Licences.*—The regulations for aerodrome licences are framed to insure that only those aerodromes which are safe for passenger work receive licences.

The dimensions laid down as a preliminary guide for the classification of aerodromes are as follows:—

800 yd. run in any direction, with good approaches, etc.	Suitable for any type of aircraft.
600 yd.	Suitable for all but the larger types of aircraft, *i.e.* not suitable for H.P.V. 1,500.
300 yd. by 400 yd.	Suitable as permanent aerodrome for aircraft of Avro 504K or similar types.
300 yd. run in any direction	Temporary aerodrome for Avro 504K and similar types.

Any aircraft may use a licensed aerodrome of the appropriate class, subject to the payment of the landing and housing fees approved at the time of the issue of the licence.

Ground Organization

(i) *Air Ports.* (*a*) *Aerodromes.*—The early aerodromes were usually any large, level grass fields, and the first real aerodromes were established in France, England, Germany and America. Their early equipment consisted only of rough sheds for aeroplanes, and fliers carried out at the local smithy or garage such repairs as could not be done on the spot or in their own homes. Repair shops were only available at a very few of the military flying grounds. As aeroplanes became more numerous, workshops equipped with power-driven machinery were established at large aerodromes such as Farnborough and Hendon, and the occupations of "aeroplane mechanic" and "aeroplane rigger" were defined. With the increase of flying, certain rules were laid down for the control of aerodromes; aeroplanes were not allowed to be moved about the aerodrome without ascertaining that they were clear of other craft alighting, and when in the air in the vicinity of aerodromes, were obliged to conform to circuit rules, *i.e.* machines were made to circle round an aerodrome in one direction, which was indicated by a coloured flag hoisted in a prominent position; and some form of indicator, such as a smudge fire, was used to afford pilots a guide to the direction of the surface wind.

From these simple rules, the complex system of aerodrome control which developed during the World War was built up. While the original principles of aerodrome management remained the same as in 1914, new inventions produced much greater efficiency. With the advent of night flying new methods of visual signalling were adopted (see below); the bucket flares, used at the beginning of the war to indicate wind direction, were replaced by electric lights or the "Money" flare; and a standardized system was introduced to permit of machines leaving and arriving at an aerodrome in quick succession both by day and night.

The results of the experience accumulated during the war in the control of aerodromes were embodied after the war in Annex D of the International Air Convention.

According to the regulations laid down therein, every aerodrome consists of three zones looking up-wind: a right-hand or taking-off zone, a left-hand or landing zone and a neutral zone. At night the taking-off and landing zones are marked by white lights placed in the position of an "L," as shown in fig. 25.

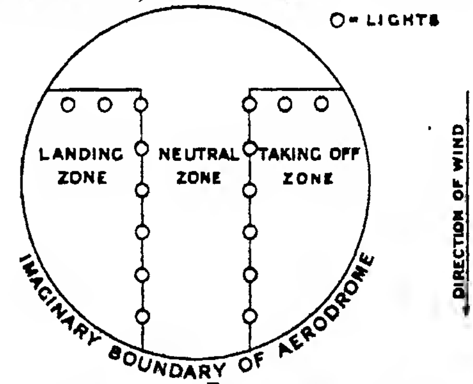

Fig. 25.

An aeroplane must land as near as possible to the neutral zone, but on the left of any aeroplanes which have already landed, and immediately taxi into the neutral zone. No aeroplane may commence to take off until the preceding aeroplane is clear of the aerodrome. A flag is hoisted in a prominent position to indicate whether an aircraft which finds it necessary to do so should make a left-handed (red flag) or right-handed (white flag) circuit. Aeroplanes must comply with this rule within 500–1,000 metres of the nearest point of the aerodrome unless flying at a height above 2,000 metres. The direction of the wind must be clearly indicated, and aeroplanes must take off or alight up-wind, those flying at a greater height being responsible for avoiding those at a lower. Aeroplanes in dis-

trees are given free way in attempting to land. At night suitable markings are required on all fixed obstacles dangerous to flying within a zone of 500 metres of an aerodrome.

The London terminal aerodrome at Croydon, Sur., may be taken as typical of a modern air-port for commercial traffic. It consists of a level grass field 900 yd. long by 800 yd. wide, and is equipped with a continental arrival and departure station, a customs office, repair shops and stores, aeroplane hangars and the private offices of companies engaged in air and road transport. An indicator, consisting of a conical linen bag, painted in conspicuous colours and attached to a mast, shows the direction of the wind by day; and the movements of machines are directed from a control tower. Along the south side of the aerodrome the name Croydon is let into the turf in chalk letters of 30 ft., legible from a height of 10,000 feet. For the assistance of night flying an aerial lighthouse shows the position of the aerodrome, while a searchlight distinguishes the aerodrome from its surroundings and illuminates the path of the machines. Electric lights are sunk into the ground to indicate the direction of the wind for landing. A wireless transmitting and receiving station is installed capable of telegraphic communication with ground stations within 400 miles and aircraft within 200 miles, and of telephonic communication within 200 and 100 miles respectively.

(*b*) *Coastal Stations.*—A sheltered stretch of water, usually an inland lake, was selected by the pioneers of hydro-aviation, a sloping beach, a rough shed and one or two small boats being the only other requirements. The equipment of the English station at Lake Windermere, the scene in 1911 of the first take-off and landing on water by a British aeroplane, was almost negligible, and it was not until 1913 that the first organized seaplane stations came into existence. The management of these stations is very similar to that of an aerodrome, with the exception of slipways up and down which aircraft are moved on leaving and entering the water, mechanical power for hauling heavy machines, and wheeled trucks to move them about on shore. At most of the early stations, however, man-power was sufficient to move machines, which were small and light, up and down the sloping beaches, while the pilot was carried to and from his seaplane while it was still afloat.

The first British flying-boat was produced in 1912, but it was not until 1915 that the larger boats were sufficiently developed to enable them to stay out on the water for days at a time. This development caused a corresponding expansion in the organization of seaplane bases. Launches and rowing-boats, used previously to assist machines in difficulties, became ferry-boats for taking fuel, stores, and personnel to and from the large flying-boats which were moored out to buoys in sheltered waters adjacent to the coastal stations. The organization and management of these depots, until the formation of the Royal Air Force in 1918, was modelled on that of H.M. ships.

Calshot, Hants., was in 1921 the most up-to-date coastal station in Great Britain; the sheltered area of Southampton Water provides ample sea room for craft getting off and alighting, while the narrow promontory on which Calshot Castle stands, almost surrounded by water, allows of numerous slipways for the handling of machines in and out of the sea at most states of the tide. Repair shops, sheds and living-quarters occupy a large area ashore; boat seaplanes, which are gradually replacing float seaplanes for all but special purposes, are moored out in a backwater; launches and rowing-boats are moored alongside a small pier, and trucks of special construction are held in readiness on the beach to move craft about on, when they have been hauled up the slipways by electric power capstans.

(*c*) *River Stations.*—The value of river stations lies in the fact that they can be located in the centre of many large cities, and passengers by air can thus save the time, now lost, in reaching aerodromes necessarily situated on the outskirts. River stations were still in 1921 in an experimental stage, but stations on the Thames, the Seine and the Spree will probably be developed to serve the three capitals—London, Paris and Berlin—which are already important airline termini.

(*d*) *Airship Harbours.*—In the early days of airships any convenient open space, such as a parade ground or moorland, was utilized, but as their size increased stations were selected so as to afford shelter from the wind, accessibility by air and road, suitable accommodation for personnel, and privacy. In 1909 the Royal Aircraft Factory, then called the Balloon Factory, Farnborough, was used for the first airship flights in England, and in 1912–3 it was provided with an elementary mooring mast. This station was abandoned in 1915. After the outbreak of the World War large airship harbours and construction stations were erected in many parts of the United Kingdom, thus following on the far greater development in Germany.

The first sheds for the housing of airships were comparatively small and constructed of various materials, such as canvas, wood or corrugated iron. As the development of the airship progressed these were superseded by sheds about 750 ft. long, built of corrugated iron on iron girders, and capable of accommodating two large rigid airships and several smaller non-rigid types. The annexes of the sheds contained all the requisite workshops for engineering, carpenter and fabric work as well as stores for general equipment and laboratories for research.

The development of the airship, however, was so rapid that it was not possible to keep pace with the construction of airship stations, which entailed considerable labour and expense. For this reason other schemes for housing had to be devised.

The first method for small airships was a reversion to the early one of "housing" them under natural shelter, but it had the disadvantage that the airship fabric rapidly deteriorated by constant exposure.

Owing, however, to the length of rigid airships it was impossible to dock them in this manner. Experiments were accordingly made for mooring them in the open by the three-wire system (*see* AIRSHIPS, Section 9). This was superseded by reversion to the mooring mast, which proved so successful that a large mast was erected at Pulham, where the first attempt was made in England to organize an airship harbour for commercial traffic, and the largest airships have been moored to it for long periods and in high winds. The adoption of the mooring mast has enabled the sheds to be mainly used for the housing of airships for the purpose of overhaul and repair, and has reduced the personnel required for handling airships on the ground from an average of about 200–350 to an average of eight men.

Airship harbours have facilities for gassing airships with hydrogen, either from steel bottles or by manufacture on the spot by the water-gas process.

(ii) *Signals.*—The methods for effecting communication with aircraft are ground signals, such as flags, pennants and ground strips; smoke signals, rockets, flares, flash lamps and searchlights; and wireless telegraphy (latterly also wireless telephony).

Visual signals for indicating wind direction and landing-grounds date from the birth of flying, while flash lamps, flares and rockets have long been used at night, or in fog. Ground strips of cloth or canvas, which are generally white on one side and black on the other so as to show up against dark and light backgrounds respectively, were placed in varying positions, according to a pre-arranged code. The flash lamp using Morse code was a little used prior to the World War, whilst the flier dropped written messages in a weighted bag attached to coloured streamers or a white parachute; early in the war the signalling-lamp (involving a knowledge of Morse by both operators) was employed.

Annex D of the International Convention prescribes that an aircraft in the air, or stationary upon land or water, but not anchored, shall carry forward and at the rear a white light, on the right side a green light, and on the left a red light. These lights, which are visible at varying dihedral angles and distances, are fixed so that only one can be seen at a time. On airships all lights are doubled. An aircraft when on the surface of the water, and not under control, displays two red lights visible all round the horizon. When moored, but not near the ground, the airship, the mooring-cable and the object to which it is moored are marked by lights or streamers.

An aircraft wishing to land at night on an aerodrome fires a green Very's light or flashes a green lamp, and makes by international Morse code the letter group forming its call sign, permission being given by the repetition of the same call sign from the ground followed by a green light. It is forbidden to land by the firing of a red light or the display of a red flare. If it is compelled to land, a red light is fired from the aircraft and a series of short flashes made by the navigation lights. When an aircraft is in distress it gives one or more of the following signals: the international SOS, the inter-

national code flag signal of distress, a square flag having either above it or below it a ball; a continuous sounding with any sound apparatus; or a succession of white Very's lights. The following signals are used to require an aircraft to land: by day, three discharges, at intervals of 10 seconds, of a projectile showing on bursting black or yellow smoke; by night, a similar projectile showing on bursting red stars or lights. In fog and bad visibility, sound signals may be used.

From the date of the formation of the British Royal Flying Corps in May 1912 the importance of wireless telegraphy in connexion with aircraft was fully recognized, both in the naval and military wings; and at a very early period of the World War its superiority over other methods of signalling from the air was clearly demonstrated. Standard patterns of instrument for naval and military work were gradually evolved; how reliable even these early types were may be seen from the fact that a few of them are actually still in use to-day in a practically identical form. The demand for the control of artillery fire by aircraft became steadily greater until, at the Armistice, on the British section of the western front alone there were over 600 aeroplanes and approximately 1,000 ground stations in use. All these machines were employing a spark system, and with the advent of the long-distance reconnaissance and bombing squadrons with their higher-powered sets the need became apparent for improvements allowing of less interference and, if possible, a larger number of machines working within the same limits of wave length.

The introduction in the early part of 1917 of the oscillation-valve continuous-wave transmitter—an extremely light and efficient instrument with a range of 100 m. from air to ground—overcame these difficulties and opened up a new vista with immense possibilities. Reception of ground-station signals by aircraft, although actually accomplished by the military wing at Farnborough as far back as 1913, became a reliably consistent proposition. Aircraft, whose duties carried them over considerable distances, were enabled to maintain a constant communication with their base, and, what was perhaps more important, the introduction of the continuous-wave set opened up the possibilities of the design of an efficient pattern of wireless telephone capable of withstanding the most rigorous usage.

Although hostilities terminated before the full benefits of these latter developments had become appreciable, the progress which has since resulted, both in service and civil aviation, is considerable. Airways have rapidly sprung into being, and the necessity for rapid signalling along the route, reporting arrivals, departures and delays of machines and of communicating with the aircraft themselves, has been responsible for the growth in England of the seven ground stations now existing, and, abroad, of the stations of the continental airports. The Air convention provides that every aircraft used in public transport and capable of carrying ten or more persons shall be equipped with sending and receiving wireless apparatus, and to-day most of the passenger-carrying aeroplanes of the London-Paris and other continental routes are equipped for the transmission and reception of wireless telephony, and are thus enabled to keep in touch with the ground throughout their flight. On several occasions during the year 1921 telephone conversation was carried out direct between a passenger flying between London and the Continent and a friend in his own home or office in London; the line telephone being used as far as the aerodrome station at Croydon, and thence being relayed by wireless telephone to the aircraft.

Another important war development, now becoming more and more extensively used, which was the outcome of the determination of the direction of passage of electro-magnetic waves, is the system of navigation by "direction finding," or "radiogoniometry." By this system two or more ground stations can detect the position of an aircraft using wireless telegraphy or telephony, and can pass that information direct to it within a few seconds.

The converse—an aircraft taking the bearing by W/T of two or more W/T stations on the ground can plot her own position, and thus enable the navigator to settle his position without asking for any information from the ground stations. This method is still in its infancy, but will undoubtedly prove of value to aerial navigation.

(iii) *Weather Information.*—The value of the collection and distribution of meteorological information for the assistance of aeronautics was early recognized, notably in Germany. In England in 1909 the Meteorological Office was represented on the Advisory Committee for Aeronautics; in 1910 a meteorological station was started at the Royal Aircraft Factory, and in 1912 at the Central Flying School at Upavon; both of these eventually prepared daily weather charts, and were the precursors of the present local distributive stations. During the war meteorological services developed under the War Office and the Admiralty, a portion of the service under the Admiralty being transferred in 1918 to the Air Ministry. In 1919–20 all branches of the Meteorological Service were coördinated and attached to the Air Ministry.

The information required for air traffic to-day consists of existing weather conditions on any route, or landing-ground forecasts and warnings. General information as to weather conditions is provided by the Daily Weather Service of the Meteorological Office, which receives information by wireless telegraph or telephone four times daily from a network of observing-stations throughout the British Isles. The reports obtained from these are issued collectively in the form of synoptic messages four times daily, and are available to anyone within wireless range either in the British Isles or European countries, while the latter distribute their local information in a similar manner. According to the code drawn up by the International Commission for Weather Telegraphy the information transmitted to the Central Office in these reports consists of surface conditions, atmospheric pressure, wind, general state of the weather, temperature, visibility, humidity, cloud, rainfall, upper-air conditions, etc., the observations relating to each element being very detailed. In addition to the above, reports and forecasts usually covering a period of 24 hours are issued four times daily to each of four Aviation Weather Groups into which the British Isles are divided. Warnings are issued from the Central Office to all flying-centres when gales are threatened.

Local distributive centres are fully equipped meteorological stations established at certain important flying-centres, especially terminals, and will eventually number about twenty. Their duties include local observation and the issue of special information to the Aviation Services within their area. The establishment of a regular air service such as that between London and Paris entails a distributive station at each terminus, subsidiary observing-stations along the route, and the hourly distribution of information. While in the air the flier can obtain information as to the weather in front of him by wireless telephony or from ground signals. (V. B.-J.)

VIII. Seaplanes

Early Attempts at Flying from the Water.—Among the earliest aircraft designed to fly from, and alight on, the water were a French craft by M. Fabre (1910), the Parseval monoplane constructed in Germany in 1911, and the Grabadini monoplane tested at Monaco in 1911. Their difficulties were considerable and their successes slight, but by the end of 1911 floats were substituted for wheels on aeroplanes that were already proved to fly; thus in Oct. of that year Glenn Curtiss, in America, flew from the water on a craft adapted from the Curtiss aeroplane which won the Gordon Bennett Trophy at Reims two years before. Its performance as a hydro-aeroplane suffered from the extra weight and resistance of the floats. In England the first flight from the water was by Comm. Swann, R.N., and S. V. Sippe on an Avro biplane with 35-H.P. Green engine at Barrow in Nov. 1911.

Henri Fabre's "Canard," an original "pusher" monoplane with a 50-H.P. Gnome engine, made several straight flights at Monaco in April 1912, and Voisin, Caudron and R. E. Pelterie thereafter successfully equipped their standard aeroplanes with Fabre floats. This float was a fairshape, rectilinear in plan, and made of a wooden framework covered with proofed canvas. This type was displaced later by pontoon-shaped floats covered with 3-ply wood or mahogany planking.

In 1912 Colliex, on a Voisin "Canard" equipped as an "amphibian" with both wheels and floats, left the land at Issy-les-Moulineaux, and alighted on the Seine at Auteuil. Donnet and Levêque in France in 1912 built and flew the first boat seaplane, a two-seater pusher having a central hull with the engine above the boat, sufficiently high under the plane for the airscrew to clear the hull. The tips of the lower plane carried small floats to balance the craft on the water, and wheels were later fitted to the hull. The high centre of thrust relative to its centre of gravity, which signalized this craft, had been demonstrated in 1909 by Blériot on an aeroplane. The design of this boat generally made it the forerunner of the seaplane of 1921. In 1912 the Royal Aircraft Factory equipped an F.E. biplane pusher with floats, and later a tractor biplane was made there and flown from Frensham Lake to Southampton Water.

At the end of 1913, Short made a 100-H.P. Gnome tractor biplane waterborne on a single central float and small wing tip-floats. On the next seaplane, however, two floats were used in place of the central float. These craft and their successors proved fairly seaworthy, and were useful on naval manoeuvres. About this time the experience of the shocks met with, when flying from broken water, led to the use of rubber shock absorbers, between the floats and the supporting struts.

In America, following the lead of Glenn Curtiss, several aeroplanes were fitted with pontoons. Towards the end of 1912 Curtiss replaced the single central pontoon by a boat-shaped

hull, which carried the tail members. To protect the crew, a wood and canvas superstructure had been built on the fore-part of the original pontoon, making its appearance very similar to that of the later Curtiss flying-boats. With experience this pontoon was extended further aft to carry the tail members, and so this flying-boat appears to have been progressively evolved.

In April 1913 a prize of £10,000 was offered by the *Daily Mail* for crossing the Atlantic in 72 hours, and Rodman Wanamaker had a two-engined (2 x 90 H.P.) Curtiss flying-boat, called the "America," made for this. Loaded to the necessary 5,000 lb. gross, it could not leave the water. With a third engine it could do so, but the air endurance was thus reduced, and in July 1914 the flight was abandoned.

War Period.—Up to July 1914 seaplane design was thus very backward, and its war usefulness to a fleet was but little indicated. The non-existence of any particular line of advance that could be systematically developed had adversely influenced its evolution. In England in 1914 seaplanes were used in coast-defence work, and one seaplane carrier was in commission. By Aug. the carrying of aircraft on board ship had been facilitated by the introduction of folding wings, and their offensive value enhanced by the successful launching of a locomotive torpedo from the air. This led to the conversion of small passenger vessels into seaplane carriers, and soon the merits and limitations of the float type of seaplane were ascertained. As no launching- or landing-deck was available, the seaplane had to be operated from the sea, and this could be undertaken only in very favourable weather. An increase of air endurance and useful load was achieved, but at the expense of some of the seaworthy qualities. With a crew of two, wireless, and about 60 lb. of bombs, an endurance of two to three hours at 70 knots was possible.

By 1915 an improvement of the same type (known as the "Short 184"), which survived throughout the war, could carry a heavier load for about five hours. They were intended mainly for duties with carrying ships, originally proposed for service with the fleet, and with the light cruiser and destroyer squadrons. As, however, these "float seaplanes" lacked sea-going qualities, and their carrier ships were vulnerable, many of the operations intended for them were abandoned. They were utilized in the Gallipoli campaign.

Air-cooled rotary engines, used on the seaplanes of 1914 because they gave the lightest weight for power where weight was a cardinal consideration, soon proved unsuitable at sea, and were replaced by water-cooled engines. "Float seaplanes" were also employed with the Grand Fleet during the first two years of the war for observation with the fleet at sea, and patrol, but they were handicapped because their sea-going qualities were not adequate for the bad weather prevalent in the North Sea. At this time only one ship was provided with a forecastle deck large enough to enable a seaplane to be launched therefrom on a light subsidiary carriage, thus avoiding the necessity for stopping the ship with the attendant risk from submarines, when getting a seaplane into the air.

In the absence of seaplanes with good sea-going qualities, ordinary aeroplanes were carried in fighting-ships with a launching-platform. Latterly carrier ships have been evolved with an alighting-deck as well. This led to the small seaplane not being pressed forward in the way the small aeroplane was by the stimulus of the war.

The "Boat Seaplane."—In 1914 there was in the British service a small Sopwith boat seaplane fitted with wheels (winner of the Mortimer Singer trophy), and also two small French and American machines. They could not carry any appreciable load nor could their wings be folded for operation from carrier ships; accordingly they were not then developed. In July 1914 Lieut. Porte, who was engaged upon the twin-engined boat seaplane, the "America," previously mentioned, was instrumental in developing the modern "boat seaplane." In 1915 several "Americas" with their two 90-H.P. engines were delivered at Felixstowe. Their performance was poor on account of their lack of horse-power for their weight, and they were too small—36 ft. hull—to give good sea-going qualities.

The much larger "Porte" boats with their three engines of 275 H.P. and air endurance of 8 hours, a total weight of about 8 tons, and a hull 60 ft. long, were laid down. The increase of dimensions carried with it a great improvement in sea-going qualities, but the air performance was but little better, and the type was not further developed. One H.P. for 20 lb. was insufficient power, and bigger engines for the weight had to be used.

The Curtiss "H8," built in America, was better in this respect. Only one of these was made, but knowledge obtained in England during its construction was embodied in its successor, the "H12." Many H12's, with 340-H.P. Rolls-Royce engines, were used with success against submarines. The H12's weighed 5 tons, carried 5 persons and 500 lb. of bombs at 80 knots for 6 hours, and were armed with three or four machine-guns. They had 1 H.P. for every 16 lb. and when first used had a higher performance than any other sea-going aircraft over the North Sea. They showed that hydroplaning efficiency, previously regarded as cardinal, could be sacrificed for sea-worthiness, provided sufficient engine-power were available.

All the earlier types, including the H8 and the H12's, were practically flat-bottomed, and pounded heavily in disturbed water; the higher power available in the latter type enabled these seaplanes to take off rapidly and the improvement of providing them with a pronounced V-section bottom was adopted first on a small "America," and then on the H8 with the two Eagle engines.

This combination of Felixstowe hull, H8 wings with Rolls-Royce engines known as the F2 was the forerunner of all the many boat seaplanes of the latter part of the war. These craft, one of which is illustrated (*see* Plate II.), corresponded in size, weight and power to the H12 type, but on account of their V-section hulls, were capable of alighting in, and taking off from, disturbed water with less risk of damage to the hulls. Their effectiveness against submarines led the Germans to evolve high-performance two-seater fighter seaplanes of the float type. Among the most effective of these were the Brandenburg monoplane seaplanes. These remarkable craft became useful as a menace to the heavier "boat seaplanes," and as they were carrying only a light machine-gun load and comparatively little fuel they out-manoeuvred them.

It has been seen that the small seaplane that might have countered these was undeveloped in England. The defensive armament of the large seaplanes was increased, though such additional load adversely affected their performance and sea-going qualities. Small two-seater seaplanes to escort the larger ones were constructed, but as these were not delivered until after the cessation of hostilities, the technical advantages to be derived from this new field of study were only partly reaped. Summarizing the above we see that the smaller boat seaplane originated in France, the large one in the United States of America, the very large one in England. Many seaplanes were brought to England from America were improved by experience obtained in Britain, and subsequently the types designed at Felixstowe and built in England were reproduced in America in quantities.

The construction of the American "NC" type, and its crossing of the Atlantic, was a wonderful achievement. The fact that from lack of fuel "NC3" alighted in mid-Atlantic, and arrived at Ponta Delgada after travelling 180 sea miles on the water in 54 hours with bad weather, pays a high tribute to the design and is a sign of the future value of the seaplane in commercial transport.

In France the war incentive to seaplane progress was lacking. France has mainly used the small boat seaplane for coast defence, and patrol for submarines. Up to the end of 1918 sufficiently high-powered engines were lacking for sea-going craft; the Hispano-Suiza 200-H.P. being in most general use.

In July 1914 the Germans had few seaplanes in service, and of these one had been imported from England. They were nearly all of the two-float type, and suffered from the defects of that type previously mentioned. Their activities were mainly defensive, and did not require either long endurance or good seaworthiness. Torpedo-carrying seaplanes were made use of in

1916 from the Belgian coast in attacks on merchant shipping, but these were not required to cover great distances, and were not remarkable. Isolated small boat seaplanes have been constructed in Germany, but not in quantity.

The Germans (no doubt in consequence of their greater study of airships) continuously kept a heavier, and more reliable, engine than the Allies, but by 1917 the Allies had produced higher-powered units, and it is probable that these two facts are mainly responsible for the German retention of the smaller "float seaplane." Moreover, their engine failures at sea were few, and there was not, therefore, so much pressure for their seaplanes to withstand open sea conditions.

The Brandenburg seaplanes of 1917–8 had rather heavy engines of 180 to 200 H.P., yet they had very high performance. Their success in fighting was due to the unusual monoplane wing arrangement which gave a clear field of fire in all directions above the horizontal plane, and to their clean general design without any external wire bracing. They employed the more recent type of twin floats.

Before the period of limitation of aircraft construction set by the Allied Commission of Aeronautical Control, the Germans had been developing the giant aeroplane in several experimental forms, differing mainly in the arrangement of multiple-engine units. These ranged in total weight roughly from 9 to 12 tons, and in the case of the larger types difficulty was experienced in providing sufficient area of contact between the wheels and ground. This difficulty did not exist in the giant seaplanes, a few examples of which had been built by the Zeppelin works on Lake Constance. Their aerodynamic design was not good, and the type was not perpetuated in its original great size on account, probably, of difficulties of control. The Staakener Giant was another example; this had two long floats made entirely of duralumin. These giant seaplanes would no doubt have developed but for the prohibition, and an interesting comparison of advantages would have been obtainable between the giant seaplane, and the giant aeroplane.

Characteristics of Seaplanes.—The boat seaplane, a craft suitable for less-sheltered waters than the early float-equipped aeroplane, or hydro-aeroplane as it was called, must, to be of real value in naval operations, be fully sea-worthy, and such progress as had been made had not yet proved by 1921 whether this was completely obtainable. But there were then:—(1) the smaller craft to operate from sheltered waters, rivers and lakes, and (2) the boat seaplane to operate oversea. The first includes all types of small dimensions of less than, say, 4 tons, and all existing "float" types in 1921 fell into this category.

To the considerations of design, stability and control applying to aeroplanes must be added the design and distribution of the float system, so that the forces due to water shall not affect adversely the stability and control. These water forces are controlled by means of the aerodynamic elements, which are ineffective except at the higher hydroplaning speeds. Hence the float system must be such that any instability that occurs between the air-borne and water-borne conditions shall take place at speeds high enough for the air controls to be dominant.

Wheeled seaplanes, for land and sea alighting, had been built by 1921 as experiments, but their development had only just begun. Their wheel system, springing, ground clearance and like factors are those of the aeroplane. These amphibians are handicapped by the weight of the float system, but show promise of very useful speed and climb.

Most large centres of population possess areas of smooth water, rivers, lakes or harbour, affording an alighting area comparable with the average aerodrome, and if the proposed route provides large water areas for any forced alighting, this fact can be taken advantage of by carrying a heavier load per sq. ft. of wing area with a corresponding gain of speed, reduction of structure-weight and increase of efficiency.

The *desiderata* for seaplanes for the open sea are less well known, and more difficult of attainment. They must for sea-worthiness be large. They had reached 15 tons by 1921 and were still far below the dimensions of the small coasting vessel; with the existing constructional materials science places a very early and definite limit to the increase of size possible. In order to enable even a 15-ton seaplane to carry a reasonable weight of fuel, crew and equipment, the load factor is in some cases reduced to three and a half. The increase of wing-loading, though it entails a higher stalling speed, and the adoption of a wing-section of high lift, may yet improve matters.

For commercial purposes, a high top speed is not so essential as for war, and model tests indicated in 1921 that the overall efficiency of a seaplane with high-lift wings may compare with craft with the usual flatter wing. The reduced area of wings so obtained has kept down the structure weight. For war the wing whose camber is variable to give high speed with good lift at low speed may be perfected.

Three arrangements of "float seaplanes" are possible; in all, the engine, crew and loads are carried in one or more fuselages well above the floats in such a way as to bring the centre of gravity and thrust axis into approximate alignment:—

(*a*) Two main floats which together support the whole weight and provide lateral and longitudinal support.

(*b*) Two main floats together with one or more tail floats, the former supporting nearly the whole weight, but being dependent on the latter for longitudinal support.

(*c*) One central main float supporting the whole weight and providing longitudinal support, two comparatively small wing floats providing lateral support.

Systems (*a*) and (*b*) provide positive metacentric height both longitudinal and transverse, while system (*c*) is always dependent on the wing floats for lateral support; for small angles of roll this is lacking, as it is necessary to carry the wing floats clear of the water when the seaplane is on an even keel.

Systems (*a*) and (*b*) are most usually employed because they avoid this defect. A main advantage of the system (*c*) is that the float impedes the view much less.

Arrangement (*a*) is better than (*b*), as the tail float of (*c*) is easily damaged, and thereupon longitudinal support being lost, the seaplane turns over on its back.

Float seaplanes have the following merits over the boat type:—

(1) They can be handled on slipways with the most primitive arrangements, and can be beached safely on any smooth foreshore.

(2) The aerodynamic elements give the normal balance, stability and control.

(3) They may be convertible into aeroplanes, or vice versa.

(4) The floats are simple in design, and can be subdivided into watertight compartments.

(5) The static transverse stability of systems (*a*) and (*b*) enable the wings to be folded afloat, for hoisting the craft from the water to a ship or a quay.

(6) For war, good arcs of fire are obtainable over the rear hemisphere.

The following are the disadvantages:—

(1) The floats are uneconomical of structure-weight.

(2) The aerodynamic drag is comparatively high.

(3) Arrangements (*a*) and (*b*) cannot be used for larger craft than 3 tons as heavy racking stresses are set up in the structure connecting the two floats when on disturbed water.

In the "boat seaplane" the displacement of the craft is borne by the central hull. Longitudinal stability on the water, both static and dynamic, is supplied by the length of the hull, and the distribution of its planing surfaces. Wing-tip floats are necessary for lateral support.

The advantages of the type are as follows:—

(1) An excellent crew position for flying and observation, *e.g.* in anti-submarine operations.

(2) Comfort: the crew can move about, the pilot be relieved, etc.

(3) Economy of structure-weight.

(4) Compact design—low air drag.

(5) Absence of racking forces, and large size possible. This last advantage is the most important, and the limit of size of aircraft, as already discussed in the section on "aeroplane design," applies here save as regards the hull. Experience shows that the hull weights do not increase even in the same proportion as the total displacement, a slight reduction in the ratio of the hull weight to total weight having been obtained, and if this continues further, it is clear that a reduction in hull weight can be set off against an increase in wing weight, resulting possibly in the most economical scale being greater than anything yet constructed

The disadvantages are:—

(1) The wings cannot be folded afloat.

(2) Cannot be beached except in very soft mud, and requires elaborate apparatus to move it to a shed on shore.

(3) In war it is difficult to defend from attack astern.

(4) The large distance between the centre of gravity and the thrust axis, and the low position of the centre of gravity in relation to the centre of lift. The former produces a variable pitching moment, the latter influences adversely the lateral control.

Elements of Design Peculiar to Seaplanes.—Many of the *desiderata* in a seaplane design are antagonistic to each other.

Flight can be achieved with 1 H.P. for each 25 lb. to be flown, but good speeds and climbing need 1 H.P. for each 8 or 10 lb.; therefore, structure-weight must be economized.

No wings can stand a blow from any large volume of water. The wings must clear the waves and any but light spray. Regarded as an aircraft the centre of gravity of the whole and the centre of pressure of the wings should be nearly coincident, and for this the centre of gravity should be high above the water. As a watercraft, however, a relatively low position of the centre of gravity is needed in relation to the waterplane. The compromise necessary puts the centre of gravity so that the metacentric height (apart from the wing-tip floats) is negative.

The position of the airscrew dominates the design. Air inflow near the blade-tips sucks spray off the sea, and picks up spray thrown by the hull, with damage to the blades. This is prevented either by putting it high up or over some part of the seaplane, *e.g.* the lower wing or hull. This places the thrust axis well above the centre of gravity, and the smaller the seaplane, the more this effect is notable. The high thrust axis produces a downward pitch varying from zero in gliding flight to a maximum at full power. In the earlier boat seaplane this was uncorrected, and, in order to get balance in normal flight, the craft was very "tail heavy" when gliding.

This effect has been diminished by placing the tail plane in the slipstream, by setting it at a negative angle to the chord of the main planes, and by distributing the weights so as to bring the centre of gravity particularly far forward. The thrust-couple thus opposed by the tail-couple can be nearly balanced out. As the main reactions on the tail are downwards, the tail plane is sometimes set with the camber downwards.

Unusually large airscrews and geared-down engines are used for efficiency at low speeds, *i.e.* at about 4/10 of the stalling speed, because the water resistances are greatest at this speed.

The hull must provide longitudinal stability, both at rest and in motion on the water. To ride in a seaway and not bury its nose when accelerating, a long forebody is used. The section of this part should be veed at the keel, and well flared at the chines, respectively to reduce shocks from on-coming waves, and to keep the divergent wave formation low and clear of the wings and airscrews. For the same reasons the keel and chine lines have a gradual rise forward with overhang forward of the fore-end of the water-line.

At least a 300% reserve of buoyancy is given to boat seaplanes to provide adequate freeboard at sea. With watertight floats 120% reserve is adequate.

Above 4/10 of the minimum flying speed, called the "hump" speed, the water resistance due to wave-making begins to fall. Above the hump speed the water resistances are probably due as much to skin friction of the planing surfaces as to wave or eddy making, and by disposing steps in the planing bottom, the wetted surface, and consequently the resistance is reduced. From the hump speed onwards these hydroplane resistances decrease, the weight is transferred more and more to the wings until the seaplane leaves the water.

The larger the planing surface (*i.e.* the wider the beam) the sooner the hull rises, and the earlier the hump occurs, but this increases the resistance at lower speeds, and makes the hull heavy for its strength.

Models tried in the Froude National Tank at Teddington (England) show that but a slight reduction of max. E.H.P. at or about the hump speed is obtained when the beam exceeds about ⅓ the length of forebody. Where a high power is available on other accounts, the beam may be still further reduced. A narrow hull with spray-deflecting sections, and without flat surfaces, or main "step," though desirable, was found not to give the necessary lowering of resistance beyond the hump speed. The resistance increased as the displacement diminished with speed.

The main "step" under the centre of gravity was proved necessary, but the area of the planing surface forward of less importance. The boundaries of the planing surfaces must have sharp edges to make the water break clear away from them; water clings to rounded surfaces even of small radius, and these would cause unnecessary resistance. The angle between the hull surface at the chines and steps should not exceed 90° for the same reason.

In a seaplane hull we require static stability at rest on the water, and dynamic stability in motion at the higher speeds. Longitudinal stability of the whole at rest is obtained by the length of the water-plane area and presents no difficulties.

The tendency of all craft to trim by the bow at low speeds is aggravated in the seaplane by the high thrust axis. The heaviest waves are formed while this tendency to dive is still present, and it is at these speeds (in the region of ⅓ to ½ of the minimum flying speed) that clean running in disturbed water is most difficult to attain.

The modern hull possesses large restoring moments at small negative angles of trim, but if the forward trim exceeds about 3°, the moments will have become negative, and an attempt to alight at such an angle will break up the hull.

Lateral stability at rest (though sought in early boat seaplanes by providing sufficient beam to give a small positive metacentric height) is destroyed by the lightest side wind, and therefore wing-tip floats are a necessity. The transverse metacentric height is always negative to-day, and wing-tip floats are relied on.

Stability in the hydroplaning condition becomes increasingly important with size. Beyond the hump speed the hydrodynamic reactions, the air reactions and, to a diminishing extent, the buoyancy combine to support the hull, and to determine the stability of the whole. Just above the hump speed hydroplaning reactions are great, while the air-forces are small; so are the moments due to the air-controls. Here the planing surfaces and steps must afford stability. When the speed increases the water-forces become less, and the air-forces greater, till, on approaching the minimum flying speed, any instability that may occur can be counterbalanced by the air-controls. In the larger seaplanes, however, the water moments may be large even at high speeds, and their hulls must, therefore, be stable over the whole range of water speeds.

The stability depends on the relative size and positions of the steps and planing surfaces, on the angles of the planing surfaces to the mean water-line to each other, and to the chords of the aerofoil surfaces; and on the position of the centre of gravity in relation to these and to the height of the thrust axis.

The problem is one of great complexity, and partly on account of its recent origin is as yet unsolved.

During the war, model work was called for on individual designs and delayed the general investigation, but clues have been found. Usually the smaller hulls are proved more apt to develop instability both in the tank tests and on the full scale. The minimum flying speed being much the same on large and small seaplanes, the wave lengths at any given speed are much the same. A hull of 45 ft. gave best results with the main step slightly forward of the C.G. and the rear step, very small relatively, 18 ft. aft of it. Here instability was delayed until the air-controls were effective, and when tried in the full scale, no instability was apparent, probably on account of the damping action of the air-surfaces, since the seaplane took the air without operation of the controls by the flier.

A somewhat similar model of a much larger seaplane with steps 32 ft. apart was stable throughout the speed range.

In the small types the hull length restricts the distance apart of the steps. The two steps may be compared to the wings and tail surfaces of an aeroplane; the main step nearly under the C.G. does the lifting of the boat on to the surface, while the rear step provides the pitching moments for equilibrium, and is most effective for this purpose when far aft and of small dimensions. Tank experiments on models show that not more than about 1/10 of the total resistance is due to the rear step and after body. The two steps must also be arranged in such a way that the intermediate hull-sections and that part of the hull carrying the tail surfaces, aft of the rear step, are clear of the two depressions formed in the water by the passage of the steps. The object is to reduce the wetted surface, aft of the main step, to the minimum necessary (at the rear step itself) to give stable conditions. This best arrangement can only be obtained, at present, by individual model experiments. The full scale has corroborated the results, and accordingly the resistance, running angles, pitching moments required for equilibrium and general characteristics of running can be obtained in the Froude tank, where waves can also be reproduced artificially. Tests show that complete stability on the model is obtained under more difficult conditions than in the full scale, hence the seaplane corresponding to a stable model may be fully relied upon.

Between Air and Water.—The water reactions on a badly designed hull may continue to be considerable up to the moment of quitting the water; then, their sudden disappearance may produce moments dangerous at a time when their correction by air-controls requires big movements. Such a seaplane at a high speed on water, and kept at the angle for maximum lift of the wings by means of the air-controls, is subject to a moment in pitch due to the water reaction on the steps. This is balanced by a moment due to the elevator until it leaves the water, when all the water forces are lost. If the elevator moment, which had been applied by the flier were positive (*i.e.* increasing the angle of attack), the seaplane would stall. These moments should either not exist or be negligible. If they do exist they are less dangerous if operative in the inverse sense to those in the example. Their existence can only be ascertained, and as a rule eventually eliminated, by experiment. From such experiments a canon for design will be evolved.

To keep hull weight low there are special methods of construction. The timbers used in boat-building practice have so far been found best. In the present sizes steel is out of the question. Aluminium alloys have been used in Germany with success for float construction, but it is doubtful whether duralumin or any other aluminium alloy is superior to mahogany for the hull skin as regards strength, hysteresis or durability. In any case of timbers, mahogany is the best for this purpose.

Unsuccessful attempts have been made to depart from the time-worn principles and practice of light boat building. A planked skin through-fastened on to timbers and stringers in the usual manner is essential for watertightness and durability.

Design is addressed to keeping down the weight of the skin, and its supporting structure. Seaplane hulls have been built having a bare weight from 20% to 9½% of the total weight. The latter figure was got on a boat displacing about 15 tons.

The two principal methods of construction are: the rigid and the flexible. For most hulls the skin is supported by a rigid structure which permits of easy subdivision by transverse bulkheads like the ordinary steel steamship except that timber is employed. The main objection to this method is its low specific strength. The rigid structure produces strong local points in the skin with intermediate areas poorly supported, resulting in sudden changes of cross section and localized deflections under load. Such a hull to have sufficient strength for taking off in disturbed water weighs 15% of its displacement at least.

The flexible method as developed by Linton Hope has its transverse sections approximately circular throughout the whole length, while the planing surfaces are built on outside the main hull, producing what is virtually a double bottom. The structure is tubular, its whole strength being concentrated in the skin and its local support-

ing members. Two or more thicknesses of mahogany-planking are through-fastened to transverse timbers of small section closely spaced; these are connected longitudinally by a large number of stringers of rectangular section lying in a radial plane, edge on to the timbers; the stringers are in turn supported on their inner edges by elm hoops of comparatively heavy section widely spaced. The small section timbers are placed so closely that no fastenings need be passed through the skin anywhere between timbers. This type is water-tight, durable and light. The average hull weighs not more than 11 % to 12 % of its displacement.

The flexibility absorbs the shocks of alighting and taking off, and precludes heavy local pressures. Care is taken to distribute the air loads, which are generally concentrated along two lines transversely to the axis of the hull, over a sufficient area of the skin, and all internal installation is arranged to allow for comparatively large relative movements of components. Transverse subdivision is practically impossible, but the provision of a subdivided double bottom is easy and effective.

Seaplane in Operation.—The preparations made for housing and upkeep of seaplanes were unfortunately dominated by the requirements of the early types. The seaplane station was modelled on aerodrome lines, with the addition of a slipway to the water. The flat floats of the float seaplanes were placed on trolleys, and thence by slipways to the water. The delicate V-section hull of the heavy boat seaplane is ill-suited for such handling. The draught of the modern boat (with a trolley under it) exceeds what can be negotiated by men in waders. If such boats are to be brought ashore at all new devices are required for doing so. Experience shows that boats of only 5 or 6 tons are damaged in such handling, though they draw little more than 2 ft. of water. To limit the bringing ashore to slack water periods in good weather, would be intolerable for commercial work. Better water-side facilities, such as covered sheds with direct access to the water for the construction, erection and repair of modern seaplanes are needed. These should allow of admitting water to part of the shed to reduce the out-of-water handling to a minimum. As a large expanse of sheltered water is necessary, and the rise and fall of the tide is important, floating sheds may be needed.

Closed sheds are not essential for operating seaplanes. The larger the seaplane the more can it resist exposure for long periods, and the practice of mooring out will become an economical necessity, but the seaplane must be designed with this in view, and proper auxiliary services for heating, fuelling and repairs provided. In high winds seaplanes moored out have risen off the water at their moorings and destroyed themselves, but this is avoidable by destroying the air-flow over the lower planes by attaching light boarding along the leading edges at a large negative angle to the chord. As the seaplane for commerce has been but little studied, marked developments may be expected in this direction; sea-worthiness is still the main problem for warcraft and increase of size the most direct solution.

In transport work, sea-worthiness is an insurance against engine failure; remove this risk and operation would take place from sheltered water only, design would be freer, size would be dictated by load, capacity and economy. The need to counter the winds rather than competition against the slow surface ship would dictate the air speed of such craft.

For operation from smooth waters structure-weight and hull weight can be reduced and wing load increased, while high-lift wing sections also offer much promise.

It is remarkable that though the viewpoint for seaplanes is so different from that for aeroplanes, the reliable engine unit is equally found to be the prime *desideratum* for present progress. (A. J. M.)

IX. Airships

Airships are divided into three main types:—(1) The rigid, which has a hull structure of rigid members covered by an outer fabric fairing, and containing a number of separate gas cells. (2) The semi-rigid, in which the whole or part of the bending and longitudinal compression induced in the ship by the rigging wires is taken by a rigid keel. The envelope from which this keel is carried is kept distended by the pressure of the gas, but is mainly subject to vertical loads. (3) The non-rigid, in which the envelope maintains its shape solely on account of an internal pressure which must exceed the outside pressure.

Small airships up to, say, 300 ft. long are necessarily non-rigid, as there is not sufficient lift to justify a rigid framework. The largest airships have a rigid hull structure because the pressures involved in an envelope of large diameter necessitate very heavy fabric and make a system of compartments essential. Between the two, the semi-rigid seeks to reduce the fabric tensions by the use of a rigid keel girder, but it is doubtful whether this justifies the keel, except as a convenient means of carrying the loads from the envelope.

A rigid airship has a hull structure of light aluminium girders, arranged with some 25 longitudinals connecting some 17 main transverse polygonal rings. At each main ring a bulkhead is formed of the load wires which suspend the weight of the keel from the upper part of the framework and the radial and chord wires which retain the shape of cross section of the ship. A specially strong keel of triangular section and some 8 ft. high runs nearly the whole length of the ship and carries the petrol tanks, water-ballast bags and other weights, being itself supported at the main transverse rings. The 30-metre spaces between the bulkheads are each fitted with a single gasbag of gas-tight fabric. The degree of fullness of these bags varies from the maximum to sometimes less than 50 % full, when the upper parts of the space alone will be occupied by the bag, whose lower part is collapsed and empty. A cover of fabric is stretched over the outside of the whole frame, so as to present a smooth surface and protect the gasbags from weather and light. Separate engine cars are attached below the hull at points along its length.

* Total weight carried for performance shown.

The early development of rigid airships was carried out by Count Zeppelin in Germany, and represents an extraordinary record of perseverance. This development was only rendered possible by political influence and by the repeated financial assistance available. The Schütte-Lanz airships were of wooden construction and developed more slowly. They appear, however, to have embodied considerably more original and perhaps courageous developments than did the Zeppelins, which were developed more as gradual minor improvements on the original design.

British Rigid Airship No. 1 was started in 1909. During the construction great consideration was given to the various auxiliary gear required by the ship and to the problems included in the handling and mooring as well as the actual flying of the ship. The thoroughness and accuracy with which this auxiliary work was developed is most remarkable in the light of later experience. Before the first flight was made the ship was moored by the bow to a mast with her cars resting on the water. The ship was broken amidships in Sept. 1911 as the result of a mistake in handling while she was being returned to her shed after one of the trials of handling before flight. Comparison of the details and estimated performance of this ship with the contemporary Zeppelins shows that she was a remarkably good first design and that had it not been decided to abandon rigid-airship construction the British development of these ships would almost certainly have become at least equal to that of Germany.

British Rigid Airship R9, by Vickers, stopped at the beginning of the World War, was restarted in July 1915 and made her first flight in Nov. 1916. She made a rather remarkable passage to Howden through a snowstorm over the Pennine range. Being somewhat inadequate in buoyancy, she was used for instruction and ultimately for mooring experiments.

She was followed by four ships of R23 class, built by Vickers, Beardmore and Armstrong, and again by R27 and R29, which were remarkable for the absence of the keel which had existed in all previous rigid airships and had been looked upon as constituting the real strength of the ship to resist bending and shearing forces. This keel subsequently reappeared in German Zeppelins and in the ships built in England, but then merely as a means of distributing to the main frames the weights of petrol tanks, etc., arranged along it.

Two wooden ships, R31 and R32, were built by Short to a design closely similar to that of the Schütte-Lanz type. They were considerably faster than contemporary ships.

Rigid-airship construction in Germany had advanced continuously and was, therefore, greatly ahead of French and British. A combination of the talent and experience of the Zeppelin and Schütte-Lanz firms early in 1916 resulted in the design of L30, giving a speed and performance far ahead of any earlier ships. L33 of this class was brought down in Sept. 1916 in such a comparatively undamaged condition that it was possible from her to prepare a design in England to which R33 and R34 were built. These ships were not, however, completed till late in 1918.

The German L65 class marked a further advance in speed and performance, while the L70 class, of which the first ship, L70, was destroyed on the first flight to England with some of the chief constructional experts on board, marked still further progress in performance and in the simplification of the machinery installation, in the adoption of fins of triangular cross section. L72, which was not actually completed until after the Armistice, had again a slightly higher performance.

After the Armistice Germany built a much smaller airship, the "Bodensee," for commercial purposes, and with her carried out a remarkable series of passenger flights. The ship was then enlarged and a sister ship, "Nordstern," also constructed.

Subsequent to the R33 class the British R36 and R37 were constructed to a generally similar design, of somewhat greater capacity and much improved detail. R80, designed and constructed by Vickers, embodied several entirely new features, but her size was so restricted by the dimensions of the construction shed that her performance was seriously handicapped. R38 made radical changes in features of design, and a clear and definite departure from German methods. The United States had contracted for its purchase. It was to be used, as it was generally understood, for an experimental service from New York to San Francisco and for that purpose masts and intermediate stations were being prepared. R38, while on the final test flight before delivery on August 24 1921, caught fire and fell owing to structural weakness, and many lives were lost.

Non-Rigid Airships.—In 1913 the chief general classes of non-rigid airships were:—(1) Those with a plain circular envelope from which the car, etc., was suspended from special fittings on

the envelope, and of which the British military airships are typical. (2) The Parseval type, in which the circular envelope is reinforced against bending under the rigging tension by Parseval trajectory bands passing over the envelope and secured to a girdle to which the car is rigged. (3) The Torres type, made by the Astra firm of Paris, trilobe in section, with riggings led inside the envelope and divided into fans secured to points along the two top ridges.

The two latter systems are intended to decrease the distance between the envelope and the car without producing excessive tendency to bend in a large ship.

At the beginning of the war the French had several non-rigid ships of various types which carried out bombing operations, but no important new ships were built. Germany had a few Parseval airships, which did a little work on the Russian front, but there was no important development of small ships. England had three small non-rigids, also one Parseval and one Astra. It became necessary, however, at the beginning of 1915 to develop the very small non-rigid airship as rapidly as possible as an anti-submarine protection. Extreme simplicity was essential in order to allow of rapid production by firms having no previous experience. For the first 30 ships aeroplane bodies were used as cars, but later special cars far more suitable for patrol work were adopted. Engines of about 90 H.P. were used and a crew of three carried. Some 150 ships of the S.S. classes were built, but at the end of the war it had been decided to adopt a slightly larger ship with twin engines and a crew of five as being more suitable for the longer patrols which became necessary. Later in 1915 a larger type—the Coastal class—having greater speed and taking a crew of five, was built. For these the Astra system of rigging was adopted in order to reduce to a minimum the necessary height of the sheds. Thirty-five of these ships and ten of an improved (C*) class were built during the war. These ships later carried a crew of five and had an endurance of 12 hours at a full speed of 51 knots. In 1916 the first ship of the North Sea type was flown. This class was intended to work with the fleet and had an endurance of some 24 hours at 50 knots. Sixteen of these ships were built.

The characteristic of these ships, more particularly the N.S. class, was that the petrol tanks and all other weights possible were carried direct on the envelope. In the N.S. class the car was separate from the power unit and the weight distributed over the length of the ship. This gave important advantages over all earlier non-rigids where the loads had been concentrated in the car. The S.S., Coastal and N.S. classes were all designed and built at the R.N. Airship Station, Kingsnorth. They constitute a very interesting development from the small supply of ships and experience available at the beginning of the war.

A considerable number of British non-rigid airships were built and supplied to the French, Italian, Russian and American services, and one Italian semi-rigid was supplied to England for experiment. A large Astra ship of some 800,000 cub. ft. capacity was built in France with two large cars. It is understood that lack of longitudinal rigidity of the envelope gave trouble.

The Italian airship design has favoured the semi-rigid type of construction, their most successful type being one in which the keel girder was not in itself rigid but "vertebrate," consisting of a number of pin-jointed frames capable of taking the longitudinal thrust induced by the car riggings, so long as the envelope held the keel in line. This system did not greatly reduce the height of the ship, as the points of attachment of the riggings were necessarily at the bottom of the envelope instead of near the level of its centre line. It did, however, enable a much lower envelope pressure to be used than in the non-rigids of the same size. This enabled a very light envelope fabric to be used and also a system of automatic pressure regulation by air taken at the nose of the airship. These ships were designed for bombing raids at great heights across the Adriatic Sea. The excellent weather conditions rendered their comparatively slow speed quite satisfactory.

Germany built a few large semi-rigids of the M type and the Parseval type. The two largest, PL26 and 27, were of some 1,150,000 cub. ft. capacity. They embodied many interesting features, including spherical partitions which divided the envelope into sections so that the accumulation of pressure at the upper end of the ship when pitched was avoided. As far as is known, no very thorough trial of these ships was made, but as far as the experiment was carried it appears to have been satisfactory. The type was not, however, proceeded with on account of the decision to concentrate on the rigid type.

Italy, after the Armistice, built a large semi-rigid "Roma," intended for transatlantic service.

An interesting aircraft which was developed experimentally as a counter to the Zeppelin raids was the "airship-plane" devised by Wing Comm. Usborne. A complete aeroplane was rigged under the envelope of an S.S. airship in such a way that, after patrolling at a great height, the envelope could be released and the aeroplane left free to deliver its attack. After several preliminary flights the first attempt to slip the envelope in flight failed on account, probably, of temporary loss of pressure in the envelope. The machine was partly released prematurely, and was damaged as it fell away; Wing Comm. Usborne and Wing Comm. Ireland were both killed. The former particularly was a most serious loss, as he had up to that time been mainly responsible for the exceptionally rapid airship development.

Kite Balloons.—The Drachen kite balloon, in the form originally used by Maj. von Parseval and Capt. von Sigsfeld in 1896, was used by the Germans immediately on the declaration of war for observation of artillery fire. Its value became at once apparent, and it was immediately copied by the Allies, very large numbers being made. The stability was, however, so poor that this type could only be used in fair weather, and accurate observation was often difficult. Capt. Caquot of the French army designed an improved arrangement of stabilizers. Three fins, one at the bottom of the tail and two 120° from it, were in the summer of 1916 ultimately adopted instead of the single fin of the Drachen and the string of parachutes which were necessary with it. Considerably improved stability was obtained, and there was an important increase of the dynamic lift which gave increased height. This type was generally adopted by the Allies for military use and worked well up to 6,000 feet. The same type of balloon was used by the navy, but was replaced by a similar one designed to resist higher wind speeds and capable of only 2,000 feet. This was used extensively by the fleet for gunnery observation and as a look-out for submarines. The balloon, being in continuous telephone communication with the captain of the ship, could transmit information more completely and rapidly than other aircraft. The balloons were also used in the ships protecting convoys, although it was sometimes contended that they acted as buoys to show the position of the convoy to a submarine which could thereby keep in touch at a safe distance during the day and deliver its attack at night. These naval balloons were capable of very high wind speeds, in one instance 80 knots being recorded.

An Italian A.P. type of balloon having a considerably smaller length to diameter ratio was adopted to give very great static lift in calm air. These were used for the apron defence against aeroplane attack. A line of balloons lifted to a height of some 15,000 ft. a horizontal cable from which hung thin vertical wires arranged to foul the wings of the hostile aircraft.

Airship Operations.—During the early days of the war French airships were employed for bombing behind the German line, but the damage to the ships, usually through gas leakage caused by shell and bullets, was so great that only a limited amount of work was done.

The Italian airships designed specially for bombing raids at very high altitude across the Adriatic obtained considerable protection from their height, and more useful results appear to have been achieved.

The Zeppelin raids over England were an interesting achievement from the airship point of view. So much of the effect of these raids was indirect, in the delays to munition work during raid nights, large amount of personnel and material retained for defence, and also in the psychological effect produced, that it is

impossible to assess the full value of this work as a warlike operation.

A less well-known Zeppelin activity was the patrol of the North Sea in conjunction with the navy. These patrols were of extraordinary extent and thoroughness, and must have proved a most valuable assistance to the naval authorities. The value of a similarly thorough patrol to the British would probably have been even greater. British airship activity was confined almost entirely to anti-submarine work carried out by non-rigid ships partly as patrols over definite areas and partly as protection to convoys. As a prevention to submarine activity these small ships were extremely effective, although the number of submarines actually destroyed through their direct agency was small. The use of a hydrophone from an airship while in flight was being successfully developed at the time of the Armistice, and promised greatly to increase the effectiveness of their work. The function of these ships was to detect and keep touch with the submarine until the surface craft arrived with better locating gear and a much more ample supply of explosive with which to carry out the actual destruction. The large ships did a certain amount of scouting work for the fleet, but this operation was really only in course of development at the time of the Armistice. The number of hours flown on patrols was over 87,000 and the distance covered well over two million miles.

One remarkable operation by the Zeppelin L57 was her flight to East Africa for the relief of the German force there. She left

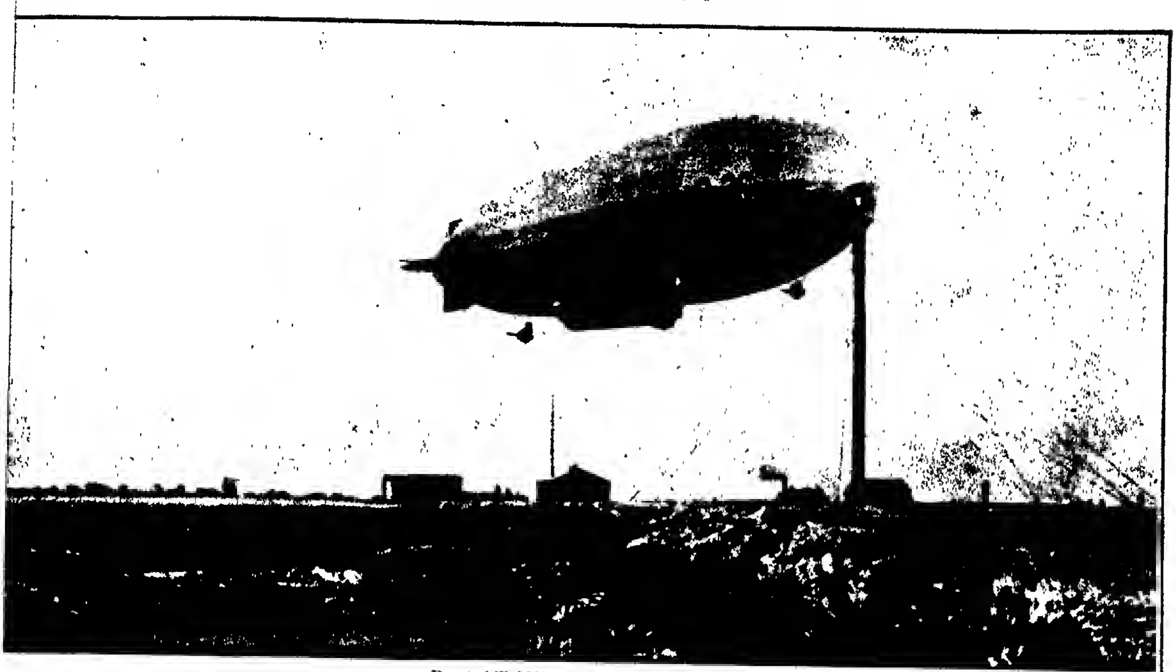
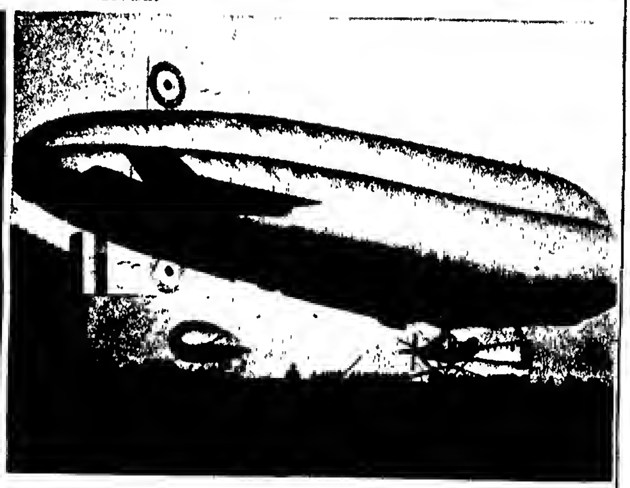
NOTE.—The trials made with the earlier ships were less complete and less accurate than those made later. The performance was in many instances calculated and recorded on a basis very different from the present standard. The figures given in the table are, however, the best that can be derived from the sources available.

The endurance depends upon the weight available for petrol when a deduction from the useful lift has been made for crew, armament, stores, etc. This deduction necessarily varies with different types of ship, and the basis on which it is made is usually not stated in the records that have been preserved. The endurance should not, therefore, be regarded as a reliable basis of comparison. The figures given are those for the best ship of each class.



R.36 AT HER MOORINGS.

S.S.Z.4 IN DOCK AT GODMERSHAM.



N.S.6.

CHANGING CREW.

TOWING C.1. FULL SPEED.

Jamboli (Bulgaria) at 4:30 A.M. on Nov. 21 1917 with over ten tons of machine-guns, ammunition and medical stores. She had passed Khartum when she was recalled and landed again at Jamboli at 5:30 A.M. Nov. 25, having covered 3,000 m. in 97 hr. with her full load of stores.

The Atlantic flight of R34 was slightly better in point of time. Leaving East Fortune, near Edinburgh, at 1:42 A.M. July 2 1919, she reached New York at 1:54 P.M. on July 6 after 108 hr. 12 min. in the air. The return journey to Pulham in Norfolk occupied only 75 hours.

The longest flight by an N.S. airship was 101 hours. The record for an S.S. ship was 51 hr., equally remarkable when it is realized that the crew of three were continuously on duty.

As indicating the regularity of the patrols, it is interesting that in 1918 from Jan. to Nov. there were only eight days on which there was no airship patrol. As showing the life of a ship, that of Coastal No. 9 at her patrol station in Cornwall may be quoted. She was inflated on July 1 1916, and deflated on Sept. 14 1918. During this 805 days she flew 2,500 hr., or an average of 3 hr. 6 min. per day, over the whole period. The deduction to be drawn from the airship operations carried out appears to be that for future warlike operations their duties will be limited to those areas where intense hostile anti-aircraft fire or hostile aeroplanes are unlikely to be met. With this reservation their uses are likely to be the same as in the past war, with a very important extension to work over undeveloped country, the airships acting as patrols and for the transport of stores. The use of a large airship as a carrier from which fighting or bombing aeroplanes could be released, and to which they could return, was considered. An aeroplane was on two occasions dropped from a rigid airship with no inconvenience or danger to the pilot. Arrangements for the complementary process of hooking on again were not completed at the time of the Armistice.

For passenger and goods transport over distances longer than the aeroplane can profitably cover at one stage the airship has important advantages. By eliminating the time spent at intermediate stops and by flying day and night with the passengers in reasonable comfort, the effective speed over a long journey is probably greater than that of the aeroplane. To this must be added the ability to make long ocean passages in safety and so to select a course as to take advantage of trade winds or local meteorological conditions.

German commercial airship activity was already in 1921 very completely planned and was only suspended by the restrictions of the Peace Treaty. The "Bodensee" had already carried out a remarkable series of flights between Berlin and Friedrichshafen, making 100 flights in 97 days and carrying in all 2,300 passengers. The ship has now been enlarged and a sister ship built in order to extend the flights to Scandinavia. Larger ships and an extension of the service to London and other capitals were contemplated, and a service of ships of considerably larger size from Cadiz to N. and S. America was planned.

Mooring and Handling.—The earliest activity of airships had been limited rather by the ability to handle them on the ground than by their ability to meet weather conditions in flight. British Rigid Airship No. 1 was moored by the bow to a mast and sheltered by a screen on Cavendish Dock, Barrow, before the ship was flown. This trial was successful, the ship remaining safe during winds with gusts up to 48 m. an hour. In the course of these trials the screen was abandoned.

The Royal Aircraft Factory in 1912 devised and used continuously for many months a new form of mooring mast to which a non-rigid airship was attached while floating in the air. To prevent the ship overriding the mast in gusty weather and to facilitate approach, the mast carried at its head a swinging cone duly counterpoised, into which the nose of the airship was drawn by a rope running down the inside of the mast. The cone was free to rotate about the axis of the mast as well as to rock vertically on a universal joint and the mast functioned satisfactorily, save that side gusts caused the cone to rub the bows of the ship with a tendency to bend it. These mast moorings were the precursors of one of the great developments in airship use, but till they were adopted generally the airship had to be housed in a shed, and hence the activity of the ship was limited to those occasions when it was possible to take her out in winds of less than 10 or 15 m. an hour with a reasonable chance of rehousing her under equally good conditions.

Under war conditions this restriction was serious, and the method of the mooring mast was again examined. A non-rigid envelope rigged with a dummy car was secured to the head of a mast at Kingsnorth, first with a cone but later with the cone removed. The ship was reinforced to take the pull of the mast, by fitting inside her bow a spar, the after-end of which was supported by a cone of cords led slightly forward and secured round a circle on the inside of the envelope. The tension in the fabric of the envelope and in these cords held the spar rigidly, and supplied the reinforcement which was necessary for stiffening the bow of the envelope while in flight and also for mooring.

A further set of experiments was carried out at Barrow with a ship secured to a short stump mast, attached to her mooring point and stepped on a lighter. The point of attachment was not on the axis. Indeed, it was so low on the envelope that side gusts produced serious rolling. Accordingly a form was devised in which a somewhat taller mast was fitted with a horseshoe head, so that fittings carried at the top of its arms could be attached to suitably reinforced points aft of the nose of the envelope. This gave support against rolling, but the point of attachment was some distance aft on the ship, and consequently the steadiness was not quite so good as when the envelope was attached by its extreme bow point.

Definitely comparative tests between mooring at the nose, using the spar inside the bow of the envelope and using the horseshoe mast were carried out at Pulham. After considerable time the internal spar of the former broke, for a reason that was not explained, and the horseshoe mast was preferred. As, however, other means were found for mooring the small ships at advanced patrol stations, the horseshoe was little employed.

Mast mooring was, however, realized to be important for rigid airships, and prolonged trials with R24 secured to the head of a mast at Pulham were instituted in July 1919 with success. The ship later remained continuously at the mast for 70 days and experienced winds up to 35 with gusts of 43 m. per hour. Difficulty was experienced in taking the ship to the mast in any but light winds.

Experiments were continued with R33 on Feb. 2 1921, and up to the beginning of June 1921 the ship had worked entirely from the mast. On a few occasions she had been into the shed, but never for more than five days. During April and May 1921 she averaged between four and five flights per week. In this case the mast is provided at its upper end with a single arm, pivoted at its middle point. Down the centre of this arm passes the wire rope, which is attached to that dropped by the ship and by which she is hauled in. This arm, therefore, comes in contact with the bow of the ship before that has actually reached the head of the rigid mast, and gives improved safety as the ship approaches the masthead. Difficulty was experienced with the control of the winch which hauls in the ship's wire. In the experiments with R24 a kite-balloon winch was employed and abandoned owing to its irregular action and control. For the experiments with R33 a steam ploughing engine was used temporarily and found to be satisfactory.

The process of landing to the mast consists in the airship dropping to the ground a rope some 1,000 ft. in length, which is then secured to the rope led from the winch up the centre of the mast and down to the ground. The winch hauls in these ropes and draws the ship to the masthead. There is no difficulty until the ship comes within some 200 ft. of the masthead, but as this distance decreases there is a tendency of the ship to swing both sideways and fore and aft, under the influence of gusts of wind. This difficulty is less serious when the ship is trimmed somewhat down by the stern, so that the wind force on the bow is approximately in the same direction as the tension in the wire. If this arrangement is not made, the variation in the wind force causes swinging of the bow of the ship, and a tendency to override and strike the head of the mast.

Even with the stern of the ship trimmed considerably down, there was still, owing to disturbed conditions, a distinct tendency to swinging, and it was often desirable to employ side-guys led from the bow of the ship to fixed points on the ground, in order to guide the bow to the masthead. With these arrangements, it was possible to secure a 60-ton ship to the head of the mast in winds of 30 m. an hour, with not more than eight men in addition to those actually in the ship.

During the time that R33 was secured to the Pulham mast, an engine was hoisted out and replaced by a spare, and a gasbag was deflated and replaced by a spare.

Three-Wire System of Mooring.—As an alternative to the system of mooring an airship to a mast, and as a more temporary arrangement, the "three-wire system" was developed from one in which the ship was secured by her mooring-point to the head of a pyramid formed of three cables, the lower ends of which were secured to the points of an equilateral triangle of some 800 ft. side.

The height of the apex was arranged to be between 100 and 200 ft. in order that the downward component of the wires when resisting the wind force should not be excessive. A considerable weight of wire was, however, necessarily supported by the ship, and a large amount of static lift was therefore necessary. This system gave considerable success during 1918, but was found defective in gusty winds owing to the liability of one wire going slack under the influence of side gusts. A wind along the axis of the ship produces a certain amount of dynamic lift which balances the downward component due to the tension in the wire. The force caused by a sideways gust produces no corresponding increase of dynamic lift, and

there is, therefore, a tendency for the lee wire to go slack. When the gust ceases and this wire draws taut, a serious impulse is brought on the bow of the ship.

It was also found that the wires of this system were so nearly horizontal that they fouled the car of R33.

To overcome these difficulties, a running system was devised. Various alternative forms were tried giving varying degrees of rigidity of support. The final system which has been found most satisfactory is that shown in fig. 26. This has the additional advantage that only the comparatively short wires, SA, SB, and SC, are carried in the ship, the remainder of the wires lying on the ground and being picked up when the ship lands. Complete experiments with this system have not been carried out, but it is considered that a ship could withstand any ordinary wind forces when secured in this way. She would be much more difficult to secure in this way than to a mast, and could not be easily supplied with water ballast, fuel or additional gas.

FIG. 26.

In order to meet the greatly increased requirements for small airships for anti-submarine patrol during the war, a system of mooring-out grounds was developed. These mooring-out stations were formed by making clearings in suitable woods and cutting a comparatively narrow avenue through the wood to the clearing. Small airships were secured in these clearings, and re-fuelled and repaired in exactly the same way as in proper sheds. The protection was so good that ships have been totally undamaged even though winds of 60 m. an hour were blowing over the top of the wood at the time.

Airship Sheds.—The construction of airship sheds has been an important item in the expense of airship work. The cost of the shed increases very rapidly with height and with the span, both of which must be considerable with any but the very small ships. Apart from the cost of the shed, there is considerable difficulty in taking a ship into the shed in any but very calm weather. When a wind is blowing across the mouth of the shed, the airship has to be hauled broadside on to the wind in order to pass in through the door, and this represents a very difficult operation when the wind is of considerable strength or of a gusty nature. In order to afford protection during this operation, all early airship sheds were provided with wind-screens running from the corners of the shed outwards parallel to the axis. These screens were of a height nearly equal to that of the shed, and afforded considerable protection against the horizontal force of the wind. They, however, caused a serious eddy to be formed, which produced a vertical disturbance on the ship nearly as difficult to overcome as the horizontal force which would have existed had there been no wind-screens present. Experiments were carried out with the wind-screens formed of expanded metal, and with screens of corrugated iron in which 30 % of the sheeting had been omitted. These screens, although they reduced the horizontal wind to a smaller extent than the solid screens, avoided the serious vertical air disturbance and were, for that reason, considerably preferable.

Experience in Germany had, however, shown that a system of rails provided with easily running trolleys was the most satisfactory system of supporting the ship against sideways forces. These rails ran out from the corners of the shed parallel to the axis, and the side-guys of the ship were attached to trolleys running on these rails. The support of the ship obtained in this way is so good that wind-screens are rendered unnecessary, and the vertical air disturbance connected with them is thereby avoided. Even with this system of handling rails, the housing of an airship presents considerable difficulties. A landing party of several hundred men is required to receive a 60-ton airship on the landing ground, to carry her to the end of the handling rails and to haul her round parallel to the rails. The air in the neighbourhood of the shed is necessarily so disturbed that considerably greater difficulty is experienced near the shed than when on the open landing ground or in the neighbourhood of a mooring mast. The difficulties connected with airship sheds are, therefore, considered to be so great that the shed must only be regarded as the dock, the mooring mast being regarded as the normal method of securing an airship between flights.

When secured to the mast the airship can be supplied with gas, water ballast and fuel. The passengers can be passed up the mast by a lift and can walk through the bow of the ship down to the cabin. The airship appears to behave satisfactorily in any wind. The most difficult conditions to meet are those in which there is no wind but rapid changes of temperature which affect the lift of the ship. This necessitates rapid adjustment of the ballast in the ship by taking in or discharging water. As long as there is a considerable wind the trim can be regulated by the elevators, as in flight.

Attempts have been made to anchor a ship to the ground by a single wire. This operation would have considerable advantages for a ship which became broken down and required to avoid drifting with the wind. At sea a drogue can be lowered into the water, and the ship will ride to it satisfactorily provided she is correctly trimmed some five degrees up by the bow in order to derive the necessary dynamic lift. It is, however, necessary to steer the ship continuously while secured in this way, exactly as though in flight. Anchoring to the ground is a considerably more difficult problem. A grapnel cannot obtain a sufficiently firm hold to resist the impulsive upward pull in the airship trail rope. Experiments were carried out with a form of dropping grapnel consisting of a large, suitably shaped weight dropped from a height of some 200 feet. This grapnel obtained a satisfactory hold either on very hard ground or on soft ground where the penetration was very deep. The hold was, however, quite unyielding, and the shock produced on the ship when thus checked was far too serious. Various forms of friction device to allow a gradual check to be brought on the ship were tried, but were never found sufficiently satisfactory for adoption.

Towing.—The earliest test in connexion with airship towing is perhaps the most interesting one. Naval Airship No. 2 broke down about 40 m. from Farnborough, and in order to save the loss of gas and the probable damage to the ship that would have attended her deflation, she was towed home by another airship, "Eta," of a slightly greater size. The operation presented no difficulty whatever. "Eta" landed alongside the damaged ship; a wire some 600 ft. in length was laid out between the two ships; both ships were made light and allowed to rise into the air. The towing ship then went ahead slowly and towed the disabled one back to Farnborough.

Occasion for repeating this towing operation has not since presented itself, but the complete success which attended the first attempt indicates that there is no serious difficulty in connexion with it. It is probable that for certain special purposes, where large weights have to be carried and where speed is not of great importance, the towing of one or more "air barges" by an airship presents very interesting possibilities.

Naval Towing.—Various trials were made to determine the possibility of towing an airship to the scene of operations so that she should arrive there with her full supply of petrol still available.

In May 1916 a Coastal airship was, after a few preliminary tests with a motor launch, towed by a light cruiser steaming at 26 knots up, down and across a wind of some 15 knots. In a further trial the airship was hauled down to the deck of the cruiser and the crew changed and gas and fuel supplied. The same operation was carried out at a height of 150 ft. to provide for occasions when the sea was too bad to allow the airship to be brought close down. These trials were entirely satisfactory.

In Aug. 1918 a ship of the S.S. class carried out extended trials in tow of a submarine. These caused no difficulty except that it was desired to make the ship capable of being towed without a crew. Arrangements for the automatic maintenance of pressure and the greater degree of stability required caused the extension to this much more difficult operation to be abandoned.

In Nov. 1918 the towing of an S.S. ship by a destroyer was again actively being developed with a view to replacing kite-balloons by airships for convoy work. In Aug. 1919 N.S.7 carried out a long towing operation with the fleet. She was in tow continuously for some 40 hrs., and was gassed and refuelled in a wind of 30 knots.

The conclusion to be drawn from these tests is that an airship can be towed without difficulty provided she is steered and handled as in flight. The towing is little relief to the crew, but the expenditure of fuel is avoided. The crew can be changed and fuel and gas can be supplied in reasonably fair weather.

Airship Fabrics.—The outer cover of a rigid airship has to form a smooth fairing over the hull structure and gasbags. Unless it remains taut under all conditions the passage of air over it and more particularly the disturbed air in the vicinity of the airscrews gives rise to flapping, which not only increases the ship's resistance but may cause the cover to chafe and ultimately be torn. The tautness is produced and maintained by a dope, applied to the fabric partly before and partly after the sheets of fabric are laced to the hull framework. The dope is generally similar to that used on aeroplane wings, but the unsupported expanses of fabric are so large—usually 3 metres by 5 metres—that the prevention of flapping is a much more difficult problem; indeed, these surfaces are so large that the maintenance of a correct difference of pressure between the inside and the outside of the ship is more effective than exactly correct tautness. The weight of the outer cover is such a large proportion of the total of the ship that very great care must be taken to apply only the minimum of dope necessary.

The outer surface must be made reflecting in order to reduce as far as possible the amount of radiant heat absorbed and transmitted to the gas in the cells and the air inside the hull.

The pigment or dye employed in the dope must be such that the part of the light which most rapidly deteriorates the cellulose of the

gas cells is eliminated as far as possible. A certain amount of light is necessary in the keel, and this usually enters through the bottom two strakes of outer cover on which a transparent dope is used. The surface of the dope should be water-repellent in order to reduce the weight of water taken up in a rainstorm.

The fabric usually employed for the outer cover is linen weighing about 90 grms. sq. metre, although cotton, mercerised as thread before weaving, appears to have some advantages owing to its great uniformity of contraction when doped.

Gasbag fabric must primarily have good gasholding properties for the minimum weight. The strength need only be sufficient to withstand handling when the bags are being placed in the ship or are moving slightly with change of fullness.

Goldbeaters' skin—a thin membrane from the caecum of the ox—although easily permeable to moisture is extremely gastight when in good condition. The skins vary in size, but, allowing for overlaps, each skin covers about 10 in. by 4 in. In English gasbags the skins are attached to the fabric by rubber solution, as this gives rather better gastightness for a given weight. The German method is to build up the skins into large sheets some 10 metres wide and of length equal to the circumference of the bag. Fabric is then stuck to these sheets with a form of gelatine adhesive. Skin contracts as it dries, whereas fabric contracts as it absorbs moisture; great care has, therefore, to be taken that the fabric is attached to the skin sheet under correct humidity condition. The fabric in which rubber is used as the adhesive is found to give trouble in hot climates, owing to the serious contraction of the skins and the softening of the adhesive just when good adhesion is most essential.

German experts are strongly of the opinion that the use of rubber in gasbags forms a non-conducting surface apt to become electrically charged by friction or in the vicinity of an electric storm. The use of rubber has, therefore, been abandoned in Germany since very early days.

Fabric made with glue adhesive appears satisfactory even under the most extreme tropical heat.

The envelope fabric of a non-rigid or semi-rigid ship, in addition to being gastight, must have an outer surface capable of giving protection against light and heat. It is also called upon to take very considerable tensile stresses. These are due partly to local tensions in the neighbourhood of rigging attachments; partly to a bending of the envelope as a whole, but mainly to the internal pressure which is necessary in order to maintain the shape of this class of ship. When the ship takes up a steep angle of pitch there is considerable accumulation of pressure at the upper end, and if for any reason, such as a rapid rise, the pilot allows the pressure to become excessive the tension in the envelope is more likely to approach the safe maximum than from any other cause. The tension induced by internal pressure is, therefore, the main consideration and must be regarded as a load that, although not very suddenly applied—the interval between normal and maximum being at least 15 seconds—cannot be expected to be maintained for long periods—say, more than 15 minutes. The resistance of fabric to tension varies greatly with the rate at which the load is applied. For a high rate of loading—say, 150 lb./in./min.—the load reached before failure is 10 to 20% higher than the load reached with the comparatively slow rate of 30 lb./in./min. or less.

A load sustained for really long periods gives lower strength still. A load of only 50 to 60% of that which the material will stand for, say, 10 minutes will break it after a week.

Considerably more investigation on these points is still required, but they are probably due to the manner of failure of a woven material, being one of gradual slipping of the fibres of the twisted thread.

A small local cut produces considerable reduction of tensile strength of an ordinary fabric. This is due to the concentration of stress at the ends of the cut causing the failure of individual threads in succession. Provided the cut is more than ½ in. long across the direction of tension the reduction of strength is to some 30% to 40% of the unwounded strength and is no greater until the size of the cut is such that it becomes an important proportion of the whole width of fabric in tension. In order to reduce this loss of strength fabric exposed to serious tension is usually made of 2 or 3 plies, of which one has its threads at 45° to those of the other plies which lie along and normal to the direction of tension. The threads of the diagonal ply help to redistribute the concentration of stress at the ends of the cut. The extent of this reinforcement depends upon the comparative strength of the diagonal ply and upon the nature of the material with which the plies are stuck together. The table shows with an accuracy of about 5% the wounded and unwounded strengths of typical airship fabrics built up of one or more plies of the same cotton and expressed as percentages of that of single ply, the adhesive being in each case rubber.

Fabric	Strength unwounded	Strength wounded
Single ply . . .	100	40
2-ply parallel . . .	210	70
2-ply diagonal . . .	125	90
3-ply parallel . . .	315	110
3-ply centre-ply diagonal	240	120

Rubber is particularly suitable as a doubling adhesive as it allows the requisite movement of threads for the reinforcement to take place. Glue, being a much more rigid adhesive, will allow of practically no reinforcing action by the diagonal ply.

Rubber is also a reasonably good gasproofing material and as it combines these two qualities it is almost universally employed in the construction of non-rigid airship envelopes. The fabric used for the envelopes of the N.S. airship was made of three plies of a cotton weighing 80 grms./sq. metre. The outer surface as a protection from light and heat was of 50 grms. of rubber containing a proportion of black litharge and a surface of aluminium powder. Between the outer and diagonal ply was 30 grms. of rubber and between the diagonal and inner ply 100 grms. of rubber as a gastight layer; some more recent experiments show that additional protection is given to the rubber by staining it with a suitable red dye.

Gastightness of most materials decreases considerably (4 or 5% per degree Centigrade) with increases of temperature.

A film of gelatine gives the greatest gastightness for a given weight, but its protection against the effects of moisture is a matter of considerable difficulty which has only recently been achieved with any degree of success in compound films now being developed.

Goldbeaters' skin is almost equally good, but is liable to small local defects caused in the process of preparation and building up.

An extract of the plum, cordia myxa or Turkish birdlime, has given satisfactory results in some respects, but its use has not been very fully developed.

It is important to realize that gastight fabric for airships must primarily stop the leakage of air into the gas. Loss of hydrogen is too small to be important, but the ingress of a weight of air definitely reduces the useful lift of the ship by an equal weight and this can only be partially got rid of even by the discharge of many times the volume of gas.

Airship Machinery.—In the early days the machinery of airships and aeroplanes had to be extremely light. As development proceeded, the greater length of flight of the airship made fuel economy and some other characteristics of greater importance in the airship than in the aeroplane. In England neglect of airships before the war followed by difficulties of supply during the war caused the airships to use, not a special engine suitable for this requirement, but standard aeroplane engines. This general unsuitability of the engines used for airship work caused the machinery to be by far the most unreliable part of the airship as a patrol unit.

The advent of the commercial aeroplane for long flights is in turn bringing a requirement more nearly that of the airship. Even so, an aeroplane which flies 10 hrs. before refuelling must be compared with the airship which flies 100 hrs. on one load of fuel. A machinery installation which weighs, say, 5 lb. per H.P. burns 0·5 lb. of fuel per H.P. in one hour. An aeroplane in 10 hrs. will burn a weight of fuel equal to that of its machinery. In 100 hrs. an airship will burn ten times its machinery weight. The importance of saving fuel even at the expense of increased machinery weight is therefore much greater in the airship. During much of the airship's flight some engines are run at considerably less than their full power, thus introducing the need for good fuel economy at reduced power. In an airship repairs of some magnitude can be made in flight (a cylinder has been changed, cracked water-jackets patched, magnetos changed and retimed, etc., during long flights). The machinery must therefore be arranged so that advantage can be taken of this possibility.

Arrangement of Power Units.—The low speed of an airship renders desirable a larger airscrew than in the faster aeroplane. Moreover, airscrew size is not restricted by the consideration of landing as in the aeroplane. The large airscrew makes for fuel economy, and this being cardinal has been found to justify the use of reduction gearing. The most efficient arrangement for a rigid airship includes a fly-wheel fitted to the crank-shaft of the engine driving, through a friction clutch, a gear reduction box on which is mounted a large two-bladed airscrew. In R38 350 B.H.P. is transmitted through a 3·3:1 reduction gear to a 17½-ft. airscrew, turning at 600 revs. for a ship's air speed of 60 knots. There is usually, in addition, a dog clutch and an airscrew brake, so that the airscrew can be disconnected and locked horizontal when landing. The departure from aeroplane practice is here notable.

In early airships it was usually necessary to mount the engines in the car and to transmit the power to airscrews carried on outriggers. The weight available for this transmission was so small that there was frequent trouble, which could mostly be traced to resonance at some speed within the very wide range (often from 100% to 50% of the revolutions for full speed) over which the airship engine was driven.

Belts, chains, bevel-gear boxes with long lengths of shafting were used, but all gave trouble within a few hundred hours' flight.

German rigid airships derived great benefit from the Maybach engine, which was developed at the same time as the ship's designs progressed, and was devised primarily to be suitable for airship purposes. It departed from other aero-engine practice in many respects, and though it was not till quite late in the war that a modified type of a Maybach was used in aeroplanes, the German industry gained the earliest experience of large light-weight engines.

In the British airships constructed during the war there was no intermediate shafting, the airscrew being mounted on the engine.

In some cases a reduction gear was incorporated in the engine itself. In the first ships of the N.S. class a length of shafting was used in order to give a better shape to the engine car and obtain better air-screw efficiency. This shafting had ultimately to be abandoned on account of torsional resonance, and the airscrew mounted direct on the engine. In the German rigid airships, however, where more weight was available, the reduction gear box and intermediate shafting were employed.

Pre-war British airships and the first few rigids were fitted with swivelling propellers. The airscrews were carried at the ends of horizontal arms and driven through bevel gearing so that the axis of the airscrew could be rotated about a horizontal transverse axis, and the direction of thrust of the airscrew changed from ahead to astern, up or down. The ability to exert a vertical force independent of the headway of the ship was often very valuable to the then comparatively inexperienced pilots under the bad landing facilities then existing.

Though engine failure has not the same consequences as in an aeroplane, the machinery must still be regarded as the part of the airship most frequently in need of overhaul. Experience shows that the engine cars must be easily detachable so that spare cars can be fitted and thorough overhaul made possible without excessive delay to the ship. They must be as the locomotive to the train, not as the machinery to a battleship.

Hydrogen as Fuel and Recovery of Exhaust Water as Ballast.—During a long flight the consumption of petrol so reduces the weight of the ship that, in order to restore her static equilibrium for landing or to avoid the increase of resistance if she is flown very light, it is necessary either to discharge a quantity of hydrogen or to acquire weight. The latter can be done by condensing the steam in the exhaust gas. Petrol produces steam equivalent to some 140% of its weight, and the proportion of this which can be collected depends upon the temperature and humidity of the issuing gas. The chief difficulty in the condensation is due to the fouling of the cooling surfaces with an oily deposit.

Attempts have been made to burn, as supplementary fuel, the hydrogen, which must otherwise be discharged. When burning hydrogen alone in an engine with a compression ratio of about 5:1 it is not possible to develop more than 25% of the engine's full power without serious detonation. When petrol and hydrogen are burnt together the proportion can be so adjusted that any fraction up to full power can be developed. A few of the smaller airships were fitted in this way but the system was abandoned on account of increased risk of fire.

Risk of Fire.—Apart from hostile incendiary action the risk of fire in the air is small and is mainly due to the petrol. It is thought that the use of heavy oil fuel would give added safety. The heavy oil engine at present involves prohibitive weight, but a Diesel engine capable of burning only ·38 lb. of fuel per H.P.-hour would, on the basis of 100 hrs. flight, justify an increase of machinery weight of 12 lb. per H.P. over the 5 lb. per H.P. of the petrol machinery which burns ·5 lb. per H.P. hour.

Winches (for Kite-Balloons).—The earliest form of winch used had a steam engine driving a single drum on which the wire was wound. It was mounted on a single chassis and was drawn by horses.

In 1915 the French adopted a steam winch of Col. Renard's design which was fitted with surge drums—a pair of drums round which the cable makes a number of turns in grooves of correctly formed section. These drums transmitted the whole of the engine or brake torque to the cable and allowed it to be stowed on a separate storage drum under comparatively small tension and, therefore, less subject to damage. The winding unit of this type of winch, including the surge drums, liquid brake and storage drums, was adopted, with only modifications in detail, as the standard for all future winches.

The later winches were usually driven by petrol engines independent of the motors driving the chassis which carried them.

After 1916 the German winches were made in two separate units, the motor on one and the winding unit on the other. These were treated like gun and limber and when in use were connected by a flexible shaft.

For naval purposes the standard winding unit was employed but driven by a steam engine in destroyers, an electric motor in light cruisers, and by hydraulic motor in capital ships, these being the most convenient forms of power available.

Gas for Airship Purposes.—Hydrogen is almost invariably employed for airships and balloons. Coal gas is cheaper and more universally available. It is sometimes used for free ballooning, but has a lifting power of only about half that of hydrogen. Helium, although having only 93% of the lifting power of hydrogen of equal purity, is totally non-flammable and has, therefore, signal advantages for airships exposed to attack with incendiary bullets.

Variation of Lift.—The total upward force on the airship when at rest is termed her "gross lift." If V be the volume of gas in the ship, ρh its density and ρa the density of the surrounding air:

$$\text{Lift} = V(\rho a - \rho h).$$

Variation with Height.—The lift is constant as the ship ascends until a height—termed "the pressure height"—is reached at which the gas spaces have become full and further expansion involves the loss of gas. When descending, the lift will similarly remain constant, because V varies directly and ρa and ρh inversely as the height, assuming that the temperature of gas and air remain equal. As the ship rises above pressure height, V remains constant but ρa and ρh decrease.

Variation with Barometer is nil until the ship becomes full; after that it varies directly with the barometric reading.

Variation with Temperature.—Provided the temperature of the gas exactly follows that of the surrounding air, there will be no change of lift until the ship becomes full. Then, after V has reached a maximum the lift will decrease inversely as the absolute temperature rises. Radiant heat falling on the ship raises the gas temperature sometimes as much as 40° F. and often 20° F. above that of the air. The gas temperature changes comparatively slowly as the ship moves through air of varying temperature, hence there may be a considerable difference between gas and air temperatures and this will substantially influence the lift of the airship.

Variation with Gas Purity.—Dilution of the hydrogen by ingress of air increases ρh and decreases the lift.

Standard Basis of Airship Calculations.—The variation of atmospheric density with height is a somewhat complex relation. The accepted relation is given in A.C.A. *Reports*, R.M. 509. The conditions at sea level are assumed to be: atmospheric density ·0782 lb./ft.^{3}; temperature 282° A; pressure 1,014 millibars, *i.e.* 14·7 lb./in.^{2}. As a standard basis of calculation of airship performance, the lift of hydrogen under these conditions at sea level is assumed to be 68 lb. for each thousand cubic feet. This figure corresponds to a purity of 94 per cent.

Determination of Purity.—The apparatus most usually employed measures the times taken by equal volumes of gas and air to escape through a small hole. The densities are inversely proportional to the squares of these times. An accuracy of $\pm$ 1% can be obtained with such an instrument.

The most accurate method is by chemical analysis.

Manufacture of Hydrogen.—The choice of method is governed primarily by the transport facilities and the raw materials available in any district. Those most usually employed for airship purposes are:—

The Water-Gas Process, generally employed at large fixed bases where a supply of coke is available. It yields a steady supply of gas of about 99·0% purity. Calcined spathic iron ore is oxidized at about 800° C. by steam. Hydrogen is given off and the ore is then reduced by water-gas and the process repeated. In the Lane plant the ore is contained in iron retorts heated externally by coke or spent gas. In the Messerschmidt plant the heating gas is burnt actually in contact with the ore itself.

The Electrolytic Method is employed where cheap electric power is available or where the oxygen is valuable as a by-product. Distilled water must be used and a yield of 5 to 7 cub. ft. of hydrogen per kilowatt hour with a purity of over 99% can be obtained.

The Silicon Process is employed where a rapid yield is required and where transport of raw materials is difficult. Powdered ferro-silicon (90% Si) is fed into hot 40% caustic-soda solution. One ton ferro-silicon and 2 tons of caustic give about 50,000 cub. ft. of gas of 99% purity.

In cases where transport of materials is exceptionally difficult, hydrolythe (calcium hydride made by passing hydrogen over strongly heated metallic calcium) is used with water. About 34,000 cub. ft. of hydrogen are given off per ton of hydrolythe.

Storage.—Hydrogen is usually stored in gas-holders under a pressure of some 9 in. of water. It is transported in steel cylinders under a pressure of some 2,000 lb./in.^{2} One ton of cylinders will carry some 2,600 ft.^{3} of gas at N.T.P. In Germany special Kesselwagen (tank trucks) carried 2,600 cub. ft. for a weight of one ton of tank (see T. A. Monckton, *Hydrogen Manual*, Parts 1 and 2, H. M. Stationery Office).

Helium.—Helium is present in the atmosphere as ·0004%. It is present in certain natural gases in proportions up to 2·5%. The main supplies are, however, in the natural gas in Texas, where the strength is about 1·8%, and in Canada, near Ontario, where the purity is ·3%. The process of collection is by liquefaction of the gas and by regenerative distillation. The cost, therefore, varies almost inversely as the proportion of helium present in the gas. The cost of production in a large plant working in America is about £12 per 1,000 cubic feet.

Such technical detail as has been published is contained in:—*Reports* to the Advisory Committee for Aeronautics and *Reports* to the Aeronautical Research Committee; lectures to the Royal Aeronautical Society, published in *Aeronautical Journal;* two lectures to the British Association in 1919 and 1920; lecture by Air Commodore Maitland to the Royal Society of Arts; T. A. Monckton, *Hydrogen Manual*, Parts 1 and 2 (H.M. Stationery Office); various articles in the German aeronautical press, mostly in *Illustrierte Flugwoche, Luftweg* and *Luftfahrt;* in the Italian in *L'Aeronautica* and *Gazzetta del Aviazione*, and in the French in *L'Aéronautique*.

AEROPLANE: *see* AERONAUTICS.

AEROTHERAPEUTICS.—The term "aerotherapeutics," as a special branch of medicine, might convey the idea that there are special diseases due to aviation which require special treatment.

But such is not the case, as there is no special "flying sickness" brought about solely by the pursuit of aeronautics. Although certain authorities have inclined to recognize some mechanical effects owing directly to the reduction of atmospheric pressure upon the body, this is only of importance in connexion with the air enclosed within the cavity of the middle ear and to a lesser extent as regards gas inside the intestines. Changes of absolute pressure of the atmosphere produce no mechanical effects since the altered pressure is transmitted equally in all directions through the semi-fluid body tissues. The suggestion has also been made that, owing to the diminution of atmospheric pressure, the airman may be liable to a special disease, somewhat akin to that experienced by the diver or the worker in compressed air. The cause of "diver's palsy," "caisson disease," or "compressed-air illness" is now thoroughly well established. When man is subjected to an increased air pressure he dissolves in the fluid portion of his blood a considerable amount of nitrogen from the surrounding air. When the air pressure is diminished, this nitrogen is again given off. If the diminution in pressure be rapid, then bubbles of gas are liberated inside the blood vessels, in the same way as bubbles of gas are liberated when fluid is removed from a siphon of aerated water. These bubbles then circulate in the blood and produce symptoms, according as they become lodged in the various parts of the body.

At first sight, therefore, it might be supposed that an airman making an ascent, in other words subjecting himself fairly rapidly to a diminution of the surrounding air pressure, might be liable to symptoms arising from the same cause as does "diver's palsy." This, however, is not the case, since the diminution in pressure is not sufficiently great or rapid to bring about any liberation of gases held in the blood plasma. In "diver's palsy" and "caisson disease" one is dealing with a reduction of pressure of from two to five atmospheres, whereas in flying one is generally dealing at most with a diminution of pressure of a little more than half an atmosphere, which is reached relatively slowly, and is easily within the margin of safety for the rate of decompression in compressed-air work. The idea, therefore, that airmen are subject to any special "flying sickness" of this nature may be dismissed.

Because it is stated that there is no "flying sickness" it does not mean, however, that flying may not cause bodily breakdown. Flying imposes a very definite stress upon the body, especially when flights are carried out for long periods at high altitudes. When to this is added the stress of offensive and defensive warfare in the air it is obvious that bodily breakdown as the result of "strain" is likely to ensue. But the signs and symptoms of "flying strain" are varied and might occur in an individual quite apart altogether from flying. In the World War it was found that "flying strain" was most generally characterized by a gradual loss of power to fly high, associated in varying degrees with symptoms of respiratory, cardiac and nervous derangement, such as breathlessness on exertion, quickened heart-beat, exaggerated reflexes, marked tremor of fingers and eyelids, and loss of neuromuscular control as exemplified by power to balance on one leg. Mental symptoms, generally in the form of anxiety neurosis, might or might not be present. In many cases it was difficult to say whether breakdown was to be attributed primarily to the effects of flying or to the nervous strain of aerial warfare, but such symptoms were frequently found to occur in those who had taken no part in active service in the air.

In order to appreciate the correct medical measures which must be taken in respect of the care of flying personnel, it is necessary in the first place to consider the human machine in relation to flying. The aviator provides the controlling and coördinating mechanism on which the satisfactory performance of the aeroplane depends. The pilot adds the aeroplane to himself—the "joy-stick," engine controls and so forth are appendages to his hands, the rudder bar an extension to his feet. By appropriate movements of his upper and lower limbs man is now able to fly, just as previously by appropriate arm and leg movements he was able to indulge in games or to control other forms of mechanism, as, for example, a motor-car.

To acquire the art of flight, therefore, a number of controlled and coördinated movements are necessary. It is common experience that certain people are found heavy-handed or heavy-footed and not likely to acquire the art of flying. In the apt pupil these coördinated movements are at first all made as the result of conscious effort, but later they pass into the realm of the automatic, so that eventually the expert pilot does not have to think how he flies—he just wishes his machine to perform a certain evolution and it occurs.

No elements come into the mechanical problem of flying that are not required for driving a motor-car or taking part in various sports; some men have more aptitude for flying than others, just as some have more aptitude for games.

To initiate the coördinated movements necessary for flying, the pilot relies upon certain sensory impressions. Vision is the most important. Without facilities for using his eyes a man is not able to fly. It has been found that experienced pilots cannot satisfactorily perform even a simple evolution with the eyes blindfolded. It is also well known that pilots cannot fly level in fog and may even get upside down. This is due to the temporary eclipse of the sense of vision; unaided by instruments, man will never be able to fly in a fog successfully.

Besides good visual acuity it has been found that harmonious working of the muscles moving the eyeballs is necessary, particularly for successful landing, and is lacking in a great percentage of bad landers. By careful training it has been found possible to bring about good visual judgment of distance and to turn bad landers into good ones.

For successful flying, next to vision and perhaps almost equally important, come the sensations from the skin and muscles. A pilot flies very largely by the "feel" of his machine. In addition to the "feel" of the controls, he derives much information from the "feel" of his seat, from the direction and change of direction of the wind on his face. He is also aided by hearing the singing of the wind in the wires. Hearing is of importance also in flying in so far as it enables a pilot to detect a failing engine, to operate wireless and to hear a telephone above the roar of the engine.

According to some people it has been thought very necessary that a man should have a good sense of balance, but experience has shown, as already mentioned, that "balance sense" is not sufficiently developed in any man to enable him to fly level in a fog.

But for flying it is not sufficient to be endowed with a mechanical and mental aptitude; a consideration of prime importance is physical endurance to resist the stress of high flights or flights of long duration. For endurance it is particularly important that a man be fit as regards his respiratory and circulatory mechanisms. This has been shown by the examination of fit pilots as well as of subjects who have been deemed in need of a rest or who have broken down as the result of flying strain.

The examination of successful flying officers showed that they were possessed of an efficient respiratory capacity. The examination of officers taken off flying through "flying strain" showed that their capacity was very much diminished. It was found by careful observation that this fall was due chiefly to ineffective working of the "exhaust" or expiratory side of the respiratory "bellows." The individual had lost his power to expire fully to the greatest extent. He, therefore, could not empty his lungs satisfactorily. Such a condition makes for deficient ventilation and the subject becomes very like a motor-engine in which the exhaust valves are defective and incomplete scavenging of the cylinders results. Hence we find that the airman in this condition easily gets breathless on the ground and certainly cannot fly to heights at which formerly he did not notice anything abnormal in his breathing.

For endurance and high flying, therefore, it is especially important that a flier have an adequate "bellows capacity" and that the "bellows" be particularly effective on the exhaust side. An efficient expiratory force is, therefore, very necessary to the pilot.

Examination of successful flying officers also showed that the effective pilot is possessed of an efficient circulatory system.

Observation has shown that there is a marked difference between the fit and unfit pilot in this respect. For example, the fit pilot is possessed of a regular, fairly slow pulse which gives the impression of a delightfully easy-working piece of mechanism. It is not greatly quickened by exercise and speedily returns to its normal rate. The pulse of the man unfit for flying, or unfit to learn to fly, is unduly quickened by exercise and takes considerable time to return to normal.

Circulatory efficiency also depends upon the pressure maintained in the arteries both during and between the beats of the heart. With the beat of the heart the pressure in the arteries rises: during the rest period it falls. In some people it may fall greatly, in others but a little. The examination of successful flying officers has shown that in them the fall is not great, whereas in the tired or inefficient individual the difference in the pressure during and between the beats is relatively large. The importance of a good pressure between the beats will be appreciated when it is realized that if the fall of pressure be great enough, fainting may result.

The efficiency of the circulatory mechanism of the body is intimately bound up with the efficiency of the respiratory mechanism. The abdominal cavity has sufficient vessel capacity to take the whole of the blood of the body and, in the upright or sitting posture, blood, by virtue of the effect of gravity, will tend to stagnate there unless its return to the heart is aided by the movements of respiration. In inspiration the downward thrust of the great muscle separating the chest from the abdomen, the diaphragm, acts like the piston of a pump and squeezes blood upwards into the heart, since it is prevented from escape in any other direction by means of valves placed in the vessels. During expiration the muscles of the abdominal wall and of the lower ribs squeeze inwards upon the abdominal contents and again force blood upwards to the heart.

The importance of these accessory pumps to the circulation is well exemplified in the crucifixion of a man. In the vertical posture the immobilization of the limbs and the restriction of the action of the respiratory and abdominal muscles cause blood to stagnate in the lower limbs and the abdomen, thereby contributing the principal cause of death.

Since in the machine the pilot is rendered relatively immobile in a sitting posture, it is of the greatest importance that he be possessed of efficient respiration and good abdominal tone, in order that an adequate circulation may be maintained. The importance of good abdominal tone is further emphasized by the following experiment. If a hutch rabbit, with its flabby, pendulous abdomen, be held in the vertical posture, it will soon become unconscious owing to the lack of tone of its abdominal wall; a wild rabbit, on the other hand, will not do so, owing to the fact that, on account of the exercise taken in its free open-air life, it has developed the tone of its abdominal musculature.

This emphasizes the value of sport in developing the respiratory and circulatory mechanisms, and for this reason all airmen are advised to take up sports which, besides giving eye and limb coördination, also give physical endurance by toning up the respiratory and circulatory mechanisms. The importance of sports and games in the life of the flying man cannot be overemphasized.

In addition to the power of endurance the pilot must also be possessed of quick perception and judgment, which, besides enabling him to learn to fly, will help him to meet any sudden emergency which may arise while he is in charge of his machine in the air. He must therefore possess good mental and nervous stability. Such stability is of even greater importance in the service pilot who may be called upon to undertake combatant service in the air.

Since 1878 it has been known that the chief cause of "mountain sickness" or "altitude sickness" is lack of proper oxygenation of the body owing to the rarefaction of the air breathed. Experiments conducted in rarefaction chambers as well as at high altitudes, such as Pike's Peak and Monte Rosa, have fully proved this point. In respect of life at high altitudes, however, a certain degree of bodily acclimatization takes place, which is not the case in respect of flying. In an aeroplane the length of sojourn at high altitudes is insufficient to induce any acclimatization, beyond possibly a transitory concentration of the blood plasma. In flying the effect of increasing altitude is in the first place a deepening of the respiration in order to secure the oxygen necessary to maintain the bodily functions. At the same time the heart quickens, and thus is established the beginning of a "vicious circle." For an increase in the rate of the heart-beat means an increase in the amount of work done by the heart, and this increased work entails an increased oxygen consumption, the supply of which is diminishing; thus each factor reacts unfavourably upon the other.

All the devices to render the respiration and circulation efficient will, therefore, be called into play to meet the changing conditions, so that with prolonged and repeated stress a breakdown of the respiratory and circulatory mechanisms, involving also the nervous system, is to be anticipated, unless appropriate measures are taken to mitigate the ill effects. This has been found to be the case.

The effects of flying at great altitudes were observed as the result of the high flying which became necessary during the World War. In the earlier stages of the war such flying was the exception rather than the rule. Owing to the increasing altitudes reached by aeroplanes, however, it became eventually quite an ordinary event for high-flying aeroplanes to maintain an altitude of from 20,000 to 22,000 ft. for several hours. When this first took place it was found that after a time the pilots and observers began to suffer from the effects of prolonged exposure to such altitudes. In the air the chief among these effects were breathlessness, muscular weakness and diminution of judgment followed by great bodily fatigue. This, when frequently repeated, led to the signs of breakdown already given.

Another effect of high altitudes was the onset of drowsiness or sleepiness. In some cases this was excessive and pilots have stated that they have fainted at great heights and cannot remember landing, whereas they have actually been sufficiently awake to fly the machine and land it in their own aerodrome with verbal assistance from the observer.

At great altitudes there is, therefore, either a general slackening of *moral* and loss of offensive spirit or else a feebleness of judgment which may lead a pilot into unnecessary difficulties. The effects of high altitudes upon judgment are insidious and constitute for the aviator a subtle danger.

Some flying officers eventually complained of headaches which at times came on while in the air, but more usually after landing. Vomiting and bleeding from the nose were very rare indeed. Cases of syncope were infrequent.

As with "mountain sickness," the symptoms described above are chiefly due to oxygen want and it was found that with the provision of oxygen apparatus on high-flying machines these symptoms were greatly alleviated.

As is well known it has been shown that the administration of oxygen (1) tends to keep an efficient slow pulse; (2) tends to keep up a good arterial pressure; (3) keeps off the onset of distressful breathing; (4) mitigates any ill effect due to excessive deep breathing; (5) increases the power for nervous concentration and muscular work.

In flying, particularly in high flying, it is important that the pilot be able to accommodate himself to the effects of diminished pressure upon the air enclosed within the middle ear and the air passages connected with the nose. Any hindrance, for example, to effective ventilation and drainage of the frontal sinuses in the brow may lead to headaches of varying duration. As regards the ear, the external orifice affords a wide passage by which alterations of air pressure are easily transmitted to the ear drum; on the other hand the Eustachian tubes, leading from the throat to the middle ear, are narrow passages which normally open only during the act of swallowing, and therefore do not so readily transmit changes of pressure. Any catarrhal condition or congestion of these tubes, therefore, tends to produce difficulty in the equalization of pressure within and without the tympanic cavity. Generally speaking, during an ascent the ears are

unconsciously "cleared" by swallowing, which under ordinary circumstances is sufficient to open the Eustachian tubes and equalize the pressure on both sides of the ear drum. Occasionally a very graduated self-inflation, just sufficient to open the tubes, may be required to dispel a sensation of fullness in the ears. If, however, owing to very marked obstruction of the Eustachian tubes, no equalization of pressure has taken place, then at 20,000 ft. the pressure in the external auditory meatus is approximately 380 mm., while in the middle ear it is still 760 mm. (ground level), a difference of 380 mm. tending to push the drum outwards. If, on the other hand, during the relatively slow ascent to this height equalization of pressure is made, but, owing to Eustachian obstruction, little or no equalization is made during a rapid descent, then on reaching ground level there is through the external ear a pressure of 760 mm. but only about 380 mm. in the middle ear, a pressure which forces the drum painfully inwards. Such an "invagination" of the drum is sometimes found immediately after landing in pilots who complain of deafness, discomfort or pain in the ears, headaches, dizziness, nausea and, in certain cases, vomiting and fainting in the air. In less severe cases, inspection of the ear drums often shows marked distension of the blood vessels. On enquiry it is usually ascertained that the symptoms complained of have come on during descent or immediately after landing, and are in many cases attributable to difficulty in equalizing the pressure within and without the tympanic cavity. It has been found also that one-sided obstruction of the Eustachian tubes may cause vertigo and incoördination in the air. The importance to the aviator, therefore, of adequate ventilation and drainage of the middle ear through the Eustachian tubes under rapidly varying degrees of atmospheric pressure is manifest. Broadly speaking, any condition of the nose or throat which causes or is likely to cause post-nasal or pharyngeal catarrh is a potential factor in the causation of Eustachian obstruction. Abnormal conditions of the nose, throat and ears which are apparently of trifling importance on the ground tend to become considerably aggravated in the air. Free nasal respiration and a healthy condition of the upper respiratory tract are necessary in the aviator.

From what has been written it will be seen that the medical measures to be taken as regards flying consist in (*a*) the careful selection of flying personnel; (*b*) the effective care of those selected.

In the main the case for careful selection has been presented. The great necessity of nervous stability, efficient respiration and circulation has been shown. Attention has also been directed to the important part played by vision, as well as to the necessity of a healthy state of the ears and upper air passages.

A word may be added here as to the importance of vestibular stability. As already mentioned, a man cannot fly level in a fog. In certain countries, particularly in the United States, great importance was at first attached to the supposed "motion-sensing functions" of the vestibular apparatus. On them the success or failure of candidates for flying was believed largely to depend. The sensitivity of the vestibular apparatus was tested by means of "rotation tests." As the result of special investigation, so great an importance is not assigned to these tests in England. Generally speaking, rotation tests therefore are only employed when a candidate gives a history of giddiness, train or swing sickness, suggestive of undue sensitivity of the vestibular apparatus.

At first no special medical examination was made for flying, but early in the World War medical officers with squadrons collected considerable evidence which proved that a special examination was necessary. They were constantly seeing pilots who were breaking down or had actually broken down from causes which should have precluded their admittance to the flying services.

In addition to visual defects, *otitis media*, and conditions resulting in Eustachian obstruction, numerous instances of gross nervous instability were observed amongst unfit flying officers, who could never have been accepted for the service had details of their past histories been elicited at a medical examination. In the selection of flying personnel the importance of the past history of the candidate cannot be overestimated.

Nowadays candidates in England, both for military and civil aviation, are submitted to:—

I. A surgical examination, comprising, in addition to measurement of height and weight, observations as to any existing surgical abnormality, congenital or the result of injury or disease, which is likely to impair the efficiency of the individual.

II. A medical examination, including enquiries as to previous occupation, family and personal medical history, an investigation of the various systems, including special tests for flying efficiency.

III. An examination of the eyes from the point of view of normal acuity of vision and also of good ocular muscle balance. Normal colour vision is also demanded.

IV. An examination of the ears, nose, throat and buccal cavity, including tests of hearing, the patency of Eustachian tubes, and, when deemed necessary, the sensitivity of the labyrinthine apparatus.

V. An assessment in which, after such further examination as appears necessary, a decision is formed as to the candidate's fitness for flying.

The special tests employed in the assessment of efficiency are as follow:—

For respiratory efficiency:—

1. Measurement of the respiratory capacity by means of a spirometer.
2. The length of time during which the breath can be held after full expiration and full inspiration.
3. Measurement of the expiratory force—that is, the height to which the subject can force a column of mercury with the cheeks and lips held.

For circulatory efficiency:—

4. The pulse rate sitting, standing and after regulated exercise (lifting the body weight on and off a chair five times in fifteen seconds).
5. Measurement of the systolic and diastolic arterial pressures.

For nervous stability and neuromuscular coördination:—

6. Observation of knee jerks and other reflexes.
7. Observation of presence or absence of tremor of eyelids, tongue and fingers.
8. The ability of the subject to stand steadily on one leg for 15 seconds with the eyes closed and hands to side.
9. The ability of the subject to raise from table to shoulder level and replace again an unstable rod placed on a piece of board.

Tests for endurance and resolution (testing respiratory and circulatory efficiency and nervous stability):—

10. After full expiration and full inspiration, the length of time during which the subject can support with the breath held, a column of mercury at 40 mm., the rate of the pulse being counted meanwhile.

The standards for these tests, which are used as adjuncts to the clinical examination, have been set by the examination of efficient pilots who have rendered satisfactory aerial service. Results have also been obtained from larger numbers of pilots who have partially or wholly broken down.

The duty of forming a final decision as to the candidate's fitness for air work rests with the assessor, a medical officer of wide experience. His decision is based upon a review of all the facts and observations recorded by the examiners, checked and supplemented by an examination on his part of such points as appear doubtful.

Apart from the elimination of cases which fail to satisfy the requirements in respect of the special senses of sight and hearing or show signs of organic disease of a gross or potentially disabling nature, the assessor's main duty is to ensure that the accepted candidate is possessed of a mental aptitude and a degree of stamina and nervous stability adequate to withstand the stress of training and of subsequent service in the air.

In forming an opinion on these points, no attempt is made to determine the temperamental suitability of candidates by elaborate psychological methods. In most cases the assessor is able to gain an insight into the candidate's general "mental make-up" by interrogation as to his motives for wishing to fly, by ascertaining his keenness for sports and games, and by obtaining details as to his service, if any, in the war. The evidence as to the soundness of the stock from which the candidate

comes, the illnesses from which he has suffered, the stresses to which he has been exposed and the manner in which they have been borne, are of prognostic importance. Reliable impressions are also formed in many cases in the course of ordinary clinical examination, additional aid in arriving at a decision being afforded by the candidate's method of performing the various tests of the cardiovascular, respiratory and neuromuscular systems. When deemed necessary the psychomotor reflexes may be measured.

After admission much devolves upon the medical officer in the way of careful supervision. As in other branches of the medical profession, the success of the medical officer in preventing breakdown from flying strain depends largely upon his mental aptitude for, and his attitude towards, his work. To the medical officer the flying officers under his care are so many human engines, and it is his duty to keep them as far as possible in fit condition, properly attuned, and to overhaul them periodically so that he can say whether they are wearing well or showing signs of strain, and, if the latter, to take necessary measures to prevent any disaster.

The medical officer should live as much as possible among the officers under his charge; by this means he acquires an intimate knowledge of their characters, which he may use sympathetically and confidentially as occasion arises. Each flying officer is, so to speak, an individual unit, and requires his own special study. Much of the medical officer's best work, therefore, is done in the mess, on the aerodrome, or at games. For example, indications of "fatigue" may be observed when a pilot, usually efficient, begins to land badly, or returns from a relatively simple flight unduly exhausted; when a moderate drinker begins to take more than is good for him; or when a sociable pilot prefers always to sit alone quietly reading in the corner. A little tact and sympathy on the part of the medical officer under such conditions may make all the difference between recovery and breakdown.

It should always be borne in mind that a certain number of pilots are liable to develop an "anxiety" in regard to their occupation, especially as the result of the stress of early training or of prolonged service in the air. The first symptoms of such anxiety are best detected by a medical officer knowing each of his pilots personally. Thus during the training stage much information can be gleaned by a quiet chat with an officer or cadet in regard to his sensations while in the air, either when receiving dual instruction or when learning to acquire proficiency at aerial acrobatics. The stress of the first solo flight must always be borne in mind. It must be remembered also that a young officer is generally averse to showing any sign of what he fears may be deemed cowardice. Yet, during the stages of training, he is probably constantly repressing a tendency to be afraid, which is only natural. With such an individual a frank discussion of his fear with the medical officer will frequently improve his condition. It is a great help, from the pilot's point of view, to be assured by a medical officer in whom he has confidence that he is in good condition, or that he is not a coward, and that many other pilots who have eventually "made good" have been through the same stages of "wind-up." In gleaning information as to the "anxiety state," note should be made of such points as change of habits, restlessness, irritability, tendency to jump at any sudden noise, or inability to concentrate. Enquiry should be made as to sleep and the nature of dreams or nightmares. The "anxious" pilot is particularly liable to insomnia, anxiety dreams and nightmares. In his dream or nightmare he is nearly always performing something connected with his daily duties, and failing in its performance. The importance of good refreshing sleep in a flying officer cannot be too strongly emphasized.

Periodic medical examination will also give indication of the onset of flying strain or fatigue, and if found, appropriate steps can be taken to prevent or mitigate it.

Attention has already been drawn to the great importance of the use of oxygen for flights at high altitudes or of long duration, as well as to the great value of sports and games in promoting flying skill and bodily endurance in pilots. Periodic advice by medical officers in respect of the ill effects of too much smoking or alcohol also play a part in the effective care of flying personnel. Advice may also be given in regard to the efficient protection of the body.

The intensity of the cold varies with the season of the year and with the height attained; it is accentuated also by the speed of the machine through the air. To prevent loss of body heat while flying, special suits have been designed, the cardinal principle of which is to keep the body surrounded by layers of warm air. In most cases this warmth is derived from the body, but the warming of clothing by electric means has also been tried. For warmth purposes, great thickness of clothing is by no means necessary. Underclothing should be loose-fitting; two thin garments of closely-woven texture, either of wool or silk, are better than one thick one. Research has shown that the warmth-giving power of clothing lies in the fineness of the mesh rather than in its thickness. Care should be taken to avoid orifices through which the outside air can permeate. Tight clothing should be avoided, particularly clothing which tends to hamper the movements of the chest and abdomen or to restrict the circulation of the limbs. Frequently, however, it is necessary to employ considerable additional protection for the legs, especially for the feet, and for this reason care should be taken to provide suitable additional protection in the form of warm, loose-fitting stockings.

For the protection of the face, a fairly close-fitting head and face piece of non-absorbent and non-porous material may be made, the inner surface of which will not absorb the oil or grease with which it is advisable to anoint the face when severe cold has to be endured. Over such, a woollen balaclava may be worn, and then a flying cap of close-fitting design.

For the protection of the hands a series of suitable gloves may be employed; for instance, thin silk gloves covered by woollen gloves, the whole enclosed in a leather gauntlet, which can be easily removed for delicate work. Gauntlets provided with a specially adaptable finger muff are to be recommended. In certain cases electrically heated gloves have also been employed.

For the protection of the eyes well-fitting fur-lined triplex goggles should be employed. The fogging of goggles may be prevented by certain preparations which are on the market. Some pilots prefer to employ tinted goggles; this is especially necessary for flying in the tropics, otherwise the effects of glare are soon felt.

In regard to diet, gas-producing foods are best avoided, since altitude causes expansion of the gases of the intestines, but in practice there is little need for the healthy person to worry about the constitution of his diet. It is important, however, that no flying should, under any circumstances, take place upon an empty stomach.

Before long flights it is advisable not to partake of food of too fluid a nature or of too much liquid. By this means the desire to urinate in the air during a flight is avoided. On very long flights, a supply of liquid food, such as sweetened cocoa or malted milk, may be carried in special thermos flasks. In addition compressed food in the form of tablets or chocolate may be provided.

Finally if "flying strain" supervenes the treatment necessary is such as would be applied to the condition of "fatigue" arising in any other occupation. According to his chief symptoms the patient may pass for treatment of an anxiety neurosis to the neurologist or for the treatment of respiratory and circulatory symptoms to the general physician. But it is always to be remembered that the keynote of the effective care of flying personnel lies in prevention rather than cure. (M. Fl.)

AFGHANISTAN (*see* 1.306).—The visit of the Amir Habibulla Khan to India at the beginning of 1907 was destined to exercise a powerful and beneficial influence on the attitude of the Afghan ruler during the rest of his reign throughout periods of unusual crisis and strain. It gave him the opportunity of making acquaintance with British officials and Anglo-Indian society, and the result was a new development of friendship and mutual

confidence. The effect in Afghanistan of the Anglo-Russian Convention signed on Aug. 31 of the same year was not of a similarly happy nature. Articles III. and IV. of the Convention, which provided respectively for the establishment of direct relations between Russian and Afghan frontier authorities and the maintenance of equality of commercial opportunity for British (and British-Indian) and Russian trade and traders, were interpreted by the Afghans as an attempt to interfere with the economic autonomy and political independence of their country. Article V. laid down that the Convention would only come into force on the notification of the Amir's consent to its terms. This consent, though repeatedly pressed for, was never given by the Amir.

From 1908 to 1914 the history of Afghanistan remained peaceful and uneventful, and was chiefly remarkable for the gradual introduction into the country of measures of civil, economic and military reform.

Influenced by what he had observed in India, steps were taken by the Amir to open schools, increase facilities for the education of the upper classes, establish factories, introduce telegraphs and telephones and to provide medical relief. The provision of improved military education and reforms in the training of the army were likewise taken in hand. For the above purposes a number of foreigners were imported into Afghanistan, and of these the majority were Turks. It was, however, in the direction of public works that the Amir chiefly directed his energies. Great efforts were made, largely by means of forced labour, to improve the internal communications. Metalled roads were constructed between the principal local centres, and good roads, realigned and fit for motor traffic, were constructed from Kabul to Dakka and from Kabul to Kandahar. Important irrigation canals were also constructed, notably the Nahr-i-Siraj from the Helmand river near Kala Bist; from the Kabul river near Daronta; and the Panjdeh Argandab canal from the Argandab river near Kandahar.

The outbreak of war in 1911 between Italy and Turkey created, as might be expected, a general wave of sympathy among the Afghans for their co-religionists in Turkey, and considerable sums of money were subscribed by the general public to Turkish funds.

When in Aug. 1914 war was declared between England and Germany the Amir was immediately informed by the Government of India and asked to maintain the strict neutrality of Afghanistan, and to this he gave a solemn assurance on the understanding that the safety and independence of Afghanistan were not interfered with.

On the entry of Turkey in Nov. 1914 into the war on the side of Germany, the Government of India, in communicating the event to the Amir, laid stress on the non-religious nature of the struggle, and brought to his knowledge the terms of a proclamation issued by the British Government pledging immunity from attack of the Holy Places of Arabia. The intervention of Turkey under German influence could not fail to place the Amir in a very difficult position. Public feeling in Afghanistan was profoundly stirred by this event, and the trend of popular feeling under other conditions of rulership might have led to far different results had not the Amir Habibulla Khan, faithful to his pledge, maintained throughout the long years of the war an attitude of strict and correct neutrality and enforced it upon his country, notwithstanding many temptations and inducements both from within and without his country. Within Afghanistan the voice of religious bigotry and fanaticism was loudly raised on the side of Turkey, while the opportunists proclaimed against the folly of not taking advantage of so favourable a moment for successful aggression.

More seductive still were temptations from outside. Chief among them were the persuasions of an important mission which the German Government despatched towards Afghanistan in the spring of 1915. The party were selected to comprise such elements as would be likely to appeal to Afghan sentiment—Indian seditionists were, both Mohammedan and Hindu, together with German and Turkish officers. The mission bore letters from the German chancellor, and were charged to make important revelations regarding possible future relations between Afghanistan, Germany, Austria and Turkey. The mission reached Kabul through Persia towards the end of 1915, and were dismissed in May 1916, without affecting their purpose.

The continuous and unwavering loyalty of Amir Habibulla Khan to his pledges to the British Government throughout the changing vicissitudes of the World War forms one of the most remarkable incidents of that eventful period. He not only maintained throughout the strictest neutrality of his country but successfully used his influence to preserve peace among the unruly tribes on the frontier, thereby diminishing demands on the depleted garrison of India.

With the Armistice of Nov. 1918 the World War came to an end, but Afghanistan was not long to enjoy the benefit of peace. At 3 a.m. on Feb. 20 1919 Amir Habibulla Khan was shot in his bed in his tent at Kala Gosh while touring in the district of Lamaghan. His brother Nasrulla Khan, then at Jalalabad, at once proclaimed himself Amir of Afghanistan in his stead. Prince Amanulla Khan, the third son of the late Amir by his principal wife, the Ulya Hazrat, who was then residing at Kabul as governor, was simultaneously proclaimed Amir by the people of all classes at the capital. His uncle Nasrulla Khan at once abdicated in his favour, and his elder brothers, Inayatulla Khan and Hayatulla Khan, and other members of the royal family, acknowledged his succession to the throne. The facts relating to the murder of Habibulla Khan have never been made known. Nasrulla Khan was charged with complicity and sentenced to imprisonment for life. In a letter dated March 3 1919 to the Government of India, Amanulla Khan announced his accession with protestations of friendship to the British Government. Mischievous and unfriendly influences however, so long kept in check by the wise, restraining hand of Amir Habibulla Khan, soon began to display themselves. In April the new Amir proclaimed the independence external as well as internal of Afghanistan. In the same month a mission under Gen. Wali Mohammed Khan was despatched to Moscow to institute relations with the new Soviet Government. Grossly exaggerated and unfounded reports of rebellions in India and of British tyranny in India and Mesopotamia were spread broadcast by official agency throughout the country and frontier tribes, and exhortation was addressed to all to be prepared for a call to arms. This was quickly followed by the proclamation of a *jihad* (holy war) and the cupidity of the credulous Afghan people and frontier tribes was aroused by promise of an easy conquest of India.

Early in May information accumulated to the effect that the plan of operations decided upon by the Afghan Government was to attack simultaneously on three fronts under separate generals through Dakka, Khost and Baluchistan, by hordes of Ghazis (religious fanatics) supported by regular troops. Prompt measures were accordingly taken to reënforce British forces on the Indian frontier.

The arrival of Afghan troops at the western end of the Khyber was reported on May 3, and active hostilities opened on May 8 by the occupation by Afghan regular troops of the heights commanding Landi Kotal. From there they were immediately expelled, and the British force in the Khyber, advancing into Afghanistan, occupied Dakka May 13. This prompt measure, and the menace it involved to the safety of Jalalabad, had an immediate and discouraging effect on the Afghan plan of operations, and was shortly followed on May 28 by the capture of the Afghan fortress of Spin Baldak which threatened the security of the southern capital of Kandahar.

In a letter dated May 28 the Amir addressed the Viceroy of India, definitely asking for peace and suggesting a cessation of hostilities. He was informed in a reply dated June 2 that an armistice would be granted on certain terms, which included the withdrawal of all Afghan troops from within 20 m. of the British front and the exercise of the Amir's influence in restraining the frontier tribes from further hostilities. These terms with but slight modifications were accepted by the Amir in a letter of June 11, in which he agreed to send delegates to India to discuss terms of peace and the reëstablishment of former friendly relations between the Afghan and British Governments. These delegates duly arrived at Rawalpindi on the date appointed, July 25, and peace was formally signed on Aug. 8.

The preceding narrative of the war has only referred to the brief operations in which British troops were engaged with forces of the Afghan regular army. Open hostilities by the latter against British forces may be said to have ceased on June 3. This, however, represents but a small portion of the actual fighting which took place between the outbreak of war at the beginning of May 1919 and the signing of peace in Aug. 1919. Throughout the whole of that period continuous conflict prevailed, now at one point, now at another, along the whole stretch of the north-west frontier of India from Chitral to Chaman. The rising of the frontier tribes failed, as such risings always have failed in the past, to be simultaneous, and the ardour of many tribes received a wholesome check from the news of British successes and the capture of Dakka in the north and of Spin Baldak in the south at the outset of the war. Nevertheless the call to *jihad* and the cupidity aroused by specious promises of plunder, together with the encouragement and material support given by bodies small and large of Afghan regular troops interspersed along the frontier, succeeded in causing many of the great frontier tribes, Mohmand, Afridi, Wazir, Mahsud and Shiranni, to throw themselves at one time and another against whatever appeared to be weak points

in the British line of defence or occupation. Instances of loyalty to the British Raj were, however, numerous. In the north the tribal levies of Chitral victoriously resisted continuous Afghan aggression, while in the Kurram and Swat valleys, and farther south in Baluchistan, all but a few tribes remained firm. Military operations throughout this period of struggle were of an exceptionally severe and arduous nature, owing not only to the great heat that prevails at that season of the year in the frontier tracts, but to the severe outbreak of cholera which occurred along the whole front and caused serious losses among the troops engaged. The armistice of June 11, which terminated hostilities between the regular troops on either side, had but little effect on the guerrilla warfare raging along the frontier, and this continued, notably in Waziristan, until even after the signing of peace on Aug. 8.

The treaty of peace laid down that the British Government, in view of the circumstances which led to the war, would on their part withdraw the privilege, hitherto enjoyed by former Amirs, of importing arms, ammunition and warlike munitions through India; would confiscate the arrears of the late Amir's subsidy and grant no subsidy to the present Amir, but would be prepared, if the Afghan Government gave proof, by good conduct in the meantime, of a genuine desire for friendship, to receive another Afghan mission after a period of six months, to discuss the settlement of matters of mutual interest and the reëstablishment of friendly relations. The Afghan Government on their part agreed to adhere to the Indo-Afghan frontier accepted by the late Amir, and also to assent to the early demarcation of the hitherto undemarcated portion of the line to the west of the Khyber; British troops were to remain in their present positions until this demarcation be effected.

Demarcation was satisfactorily completed and British troops accordingly evacuated Dakka on Sept. 13. The Afghan fort of Spin Baldak had been previously evacuated on Aug. 14.

It will be noticed that the treaty of peace marks an important departure from previous practice in that no mention is made in it of the dependence of Afghanistan on the British Government in external affairs, in regard to which previous Amirs, 'Abdurrahman and Habibulla Khan, had bound themselves to follow the advice of that Government. In a letter handed by the Foreign Secretary to the Government of India to the Afghan delegate immediately after the signature of the treaty it was expressly stated that that treaty left Afghanistan free and independent in its affairs both internal and external.

Reference has been made to the despatch in April 1919 of an Afghan mission to the Soviet Government at Moscow. This mission, under Wali Mohammed Khan, reached Moscow in Oct., and were well received. Meanwhile, in Sept. 1919 the Soviet Government of Turkestan despatched a mission to Kabul under M. Bravin, a former member of the Russian imperial consular service. In Nov. 1919 the Soviet Government of Moscow, desiring to establish a more direct control by themselves of foreign relations in Asia, also sent a mission under M. Suritz, which reached Kabul in Jan. 1920. M. Suritz, superseding M. Bravin, at once commenced negotiations with the Afghan Government, and in the course of the summer despatched to Moscow the draft of a treaty which, it is understood, provided for the grant of a subsidy to the Amir, the supply of material assistance and expert instructors and the establishment of Russian consulates in both eastern and northern Afghanistan.

In the meantime, after a lengthy correspondence between the Indian and Afghan Governments, it was decided that an Afghan mission, as arranged in the treaty of peace of Aug. 8 1919, should be sent to India. They arrived at Mussoorie on April 14 1920, under the charge of Sardar Mahmud Beg Tarai, the Afghan Foreign Minister, and were met by a British delegation under Sir Henry Dobbs, the Foreign Secretary to the Government of India. The conference lasted until July 24, when the Afghan delegation were presented with a statement of the general lines on which the British Government were prepared to discuss a formal treaty. Throughout this period the attitude of the Afghan Government in respect to questions under discussion was swayed backwards and forwards by outside concurrent events, notably by the steady strengthening of the Turkish Nationalist position in Anatolia, the change of Government and the growth of Bolshevik influence in Persia, the outbreak of revolt in Mesopotamia, and by the increase of political agitation in India. Nearer home also, a renewed outbreak of hostilities, fostered and assisted by Afghan agency, on the Indo-Afghan frontier in Waziristan, led to lengthy military operations, and raised hopes in the mind of the Afghan Government that the British Government would not be indisposed to consider the question of changes in favour of Afghanistan of the Indo-Afghan boundary.

On Oct. 16 1920 the Soviet Government of Moscow signed a treaty with Afghanistan, subject to ratification by the Amir. The exact terms of this treaty were still unknown in Nov. 1921, but were understood to be on the lines of the draft prepared in April by the Suritz mission. In Nov. 1920 the Turkish general, Jemal Pasha, arrived in Kabul on a special politico-military mission; and in 1921 a British mission under Sir Henry Dobbs was also sent to Kabul.

(A. H. McM.)

AFRICA (*see* 1.320).—Territorial changes in Africa between 1910 and 1921 resulted in a repartition of large areas of the continent; knowledge of its physical features largely increased and means of communication developed. Social and economic factors, affecting all races, acquired new values. The present article surveys these matters broadly under the headings: (1) Exploration; (2) Communications; (3) History.

1. *Exploration.*—The largest unknown area of Africa in 1910 was in the Sahara, of which the central part only had been adequately explored. French officers had begun as early as 1904 to make itineraries in the Western Sahara. These were continued by Gen. Laperrine, Capt. Martin, Capt. Mougin, Capt. Augiéras and others. A long-cherished design was realized on Christmas-day when, in mid desert, a column under Capt. Augiéras coming from Algeria effected a junction with a column under Maj. Lauzanne which had started from Atar in Mauretania. The result of these 18 years of work was that by 1921 a roughly accurate knowledge of the region had been obtained. The Western Sahara consists of a central dome (the Eglab) of moderate elevation, almost surrounded by great tracts of sand dunes. The "central dome," though uninhabited, contains habitable regions, and is regularly traversed by organised bands of brigands who set out from Southern Morocco to pillage the tribes of Mauretania and the middle Niger. Abundant traces of ancient human occupation in the Western Sahara have been discovered; except that they are pre-Islamic it has been impossible even approximately to fix their age. The great depression known as the Juf, to the N.E. of Timbuktu, remained unexplored up to 1922.

But it was in the region bordering the southern end of the Eastern Sahara, and in the Libyan desert itself that the greatest gaps existed in the map of Africa in 1910. Several of these gaps were filled, and the chief remaining problems in the hydrography and orography of Africa were solved by Lieut.-Col. Jean Tilho and his colleagues in an expedition extending from 1912–7. The main object of Col. Tilho was to ascertain whether the basin of the Chad was closed or belonged to that of the Nile, and that thus there was, as tradition asserted, a water connexion between the Niger and the Nile (*see* 19.676). In a previous expedition (1908–9) Tilho had found that the Soro (the Bahr-el-Ghazal channel running E. of the Chad) was of the same level as the lake for a very considerable distance. The 1912–7 expedition discovered that a mountainous barrier encircled the basin of the Chad from N. to S.E., that is, it had no fluvial connexion with the Nile basin. But N.E. of the lake is a low-lying zone of which the lowest point is 520 ft. below the level of Chad. This point is in the recently dried-up bed of the lake of Kirri and is some 250 m. from Lake Chad. Thus Chad was proved to be but the remains of a vast lake comparable in size to the Caspian. The Tilho expedition also explored the Tibesti and Ennedi (Endi) mountains, and discovered another massif, that of Erdi, connecting Tibesti and Ennedi. It also learned of the existence in the Libyan desert of another mountain mass, the Jebel el Auniat (about 150 m. S.E. of Kufra), with heights probably exceeding 4,000 feet. Hypsometric determinations enabled the expedition to ascertain the heights of the chief summits of the mountain chains between Chad and the Nile. The highest points are Emi Kussi, 11,200 ft. (an extinct volcano), and Tusside, 10,700 ft., in Tibesti, and (the) Jebel Marra, 9,800 ft., in Darfur.[1] The exact longitude of many places was determined by wireless time signals from the Eiffel Tower, and a chain of astronomical positions completed the connexion of the maps of the Niger, Chad and Nile. Some 7,000 m. of surveys were made by the expedition. Particular interest centred in the exploration of Tibesti, which had been seen by one European only (Nachtigal in 1869) until it was reached by Comdt. Lofter in Dec. 1913. It had been thought that Tibesti might prove a well-watered fertile region, but though it contains pasture lands, palm-groves, and flowing rivers it is mainly arid—a magnificent mountain-mass with deep gorges and serrated ridges, falling eastward in giant steps; westward overlooking a boundless plain.

Of the Libyan desert Mr. W. J. Harding King collected much information from native sources and himself investigated its north-western fringe. Early in Jan. 1921 Mrs. Rosita Forbes, a young Englishwoman, reached Kufra from Cyrenaica, and the following month travelled to Jarabub by a new route. Except by a French prisoner of the Senussites who was interned there in 1916, Kufra had only once before been visited by Europeans—by Rohlfs and Anton Stecker in 1879—and Mrs. Forbes showed that the extent of the oases was less than supposed and their position incorrectly mapped. Evidence of increasing desiccation of the desert was obtained—one stretch of 350 m. traversed was without a well or water of any sort.

In the upper Nile basin Capt. H. D. Pearson, director of surveys in the Sudan, explored (1911–2) in part the head streams of the Pibor, the main western branch of the Sobat. Captain H. A. Darley investigated other parts of the Sobat system and Capt. R. H. Leeke in 1912–4 explored the adjacent southern region—that between the Bahr-el-Jebel (Mountain Nile) and Lake Rudolf. The chief feature of the country was shown to be the escarpment

[1] These figures are subject to rectification on the full working-out of the data obtained by the expedition.

forming the Nile–Rudolf watershed, which drops abruptly into the Turkana plain on the Rudolf side, but slopes gradually westwards to the Nile. It has heights of 10,000 feet. The expeditions named nearly completed the exploration of the region between the Nile and Abyssinia. In 1915–6 Maj. Cuthbert Christy made a ten months' journey along the Congo–Nile divide, where it forms the frontier of the Anglo-Egyptian Sudan. The divide proved to be "a continuous and more or less level strip of bush-covered country (mostly of ironstone formation), sometimes as much as two miles in width but often only a few yards." In Maj. Christy's opinion the divide was perfectly suitable for the building of a railway, a roundabout link in the Cape-to-Cairo scheme.

Mr. I. N. Dracopoli in 1912–3 explored part of southern Jubaland. He reached the Lorian Swamp—which receives the waters of the Uaso Nyiro—and solved the problem of its outflow. He found that the Lake Dora issues from Lorian in a well-defined bed and, though usually dry in its lower course, is, through Lake Wama, a tributary of the Juba river. Mr. (afterwards Sir) G. F. Archer completed in April 1912, after over two years' work, surveys connecting the triangulation of British East Africa with Maj. Gwynn's Abyssinian boundary survey. Captain R. E. Salkeld in 1913–4 further explored Jubaland, drawing attention to the overrunning of that region by the Somalis—the most recent instance of the migration of African races.

In east central Africa a survey by Capt. E. M. Jack, in 1911, of the region N.E. of Lake Kivu and W. of Victoria Nyanza resulted in making known a healthy highland region and added to the knowledge of the Mfumbiro range of active volcanoes. Karisimbi was found to be 14,780 ft. high. In Dec. 1912, Sir A. Sharpe and Mr. M. Elphinstone witnessed the formation of a new volcano, named Katarusi, which, following an earthquake, rose out of an old grass-covered lava-field, sending into the N.E. corner of Kivu a river of lava which filled up a "large bay."

The first survey along its whole length of the Congo–Zambezi watershed was made in 1911–4 by Anglo-Belgian and Anglo-Portuguese boundary commissions, the principal commissioners being Capt. Everest (killed by a lion), Maj. E. A. Steel and Maj. Reginald Walker (British), Maj. Begraud and Capt. Weber (Belgian) and Capts. C. V. Cago Coutinho and V. da Rocha (Portuguese). As in the Congo–Nile watershed, it was found that many rivers ran for considerable distances parallel to the divide, which is largely bush-covered. Major Walker discovered that the Luapula (the main eastern headstream of the Congo) did not, as was believed, issue from Lake Bangweulu, but was a continuation of the Chambezi, which passes through the great swamp S. of Bangweulu.

Another boundary commission, under Capt. W. V. Nugent and Oberleutnant Detzner, in 1912–3 demarcated the Nigeria–Cameroon frontier between Yola and the Cross river. The frontier followed roughly the edge of the highlands overlooking the fertile plains of the Benue and was an instance where the straight lines drawn on the map by diplomatists to mark international boundaries worked out fairly well in practice.

During the World War exigencies of campaigning led to many additions to exact knowledge of the topography of tropical Africa, partly through the use of aircraft for survey purposes. Thus very useful maps, showing routes unsuspected on the ground, were made of Portuguese Nyasaland by airmen. In 1920 Dr. P. Chalmers Mitchell, who passed over the whole length of the Nile basin in an aeroplane, proved the value to geology of air reconnaissances by the discovery in the Bayuda desert N. of Khartoum, of the volcanic character of a range of hills. Between Old Merowe and Atbara the aeroplane crossed "a high and irregular range of hills running east and west. In the middle of them was a great plain looking like toffee poured out on a plate. From this a number of craters rose, two large, one with a sandy interior with thorn bushes, the other with a second peak and crater inside the outer rim." From pieces of tufa recently obtained from the Nile Valley, N. of Khartoum, the existence of some unknown Tertiary volcanic field in that region had been suspected. Exploration on the ground remained to be undertaken, but Dr. Chalmers Mitchell's observations would appear to be the first important geological discovery made from the air.

2. *Communications.*—The first railway and steamer route across Africa was completed by the opening in March 1915 of a railway from Kabalo on the Lualaba (Upper Congo) to Albertville on the west shores of Lake Tanganyika. The year before (1914) the German railway from Dar es Salaam had reached Kigoma, on the east shores of Tanganyika. A part of this Atlantic–Indian Ocean route is by the Congo, the non-navigable stretches of the river being bridged by railway. An all-rail east-west route across South Africa had also been effected in 1915, when a line was built from Prieska to Kalkfontein connecting the S.A. system with that of German South-West Africa. By this means Walfish Bay and Delagoa Bay were linked by railway. A second east-west all-rail route across Africa will be provided by the railway from Lobito Bay to Katanga, where it will join the lines to Beira and other east-coast ports, as well as to Cape Town. In 1920 some 600 m. of rails remained to be laid on this route. The surveys had been completed in 1920 and construction began in 1921.

None of these lines was designed as a transcontinental route, though the Dar es Salaam–Congo route was so used for passenger traffic.

With the Cape-to-Cairo scheme little progress was made in the period 1910–21. The railway from Cape Town via Bulawayo and the Victoria Falls, which had reached the Belgian Congo frontier in 1909, was however continued N. across Katanga to Bukama on the Lualaba (Upper Congo), the line being completed in May 1918—an addition of 442 m. in ten years, making a through service from the Cape, on the same gauge (3 ft. 6 in.), of 2,398 miles. In 1921 the construction of a further section of the railway to a more northerly point on the Lualaba where navigation was easier than at Bukama, was begun. But from 1918 it was possible, by utilizing the Congo and Tanganyika systems, to travel alternately by train and steamer from the Cape to Cairo, with only two breaks—together not more than 300 m.—to be covered on foot. The southern break was from Tabora (on the Tanganyika railway) to Mwanza, on Victoria Nyanza; the northern from Nimule to Rejaf, along the banks of an unnavigable stretch of the Upper Nile.

These cross-Africa routes were valueless for through goods traffic; their function was to bring the produce of Central Africa direct to the nearest seaport. Thus the Tanganyika railway made Dar es Salaam the natural outlet for the trade of a large portion of the eastern part of the Belgian Congo. With these main routes may be mentioned the line (built 1916–8) from Qantara on the Suez Canal, across the Sinai peninsula to Gaza, which put Africa and Asia in direct railway communication, Cairo being linked with Jerusalem, Damascus, Aleppo, etc.

With regard to trans-Saharan railways, from Algeria to the Niger countries, surveys made in 1912–3 showed that there were routes presenting no engineering difficulties. From Msala, in the Algerian Sahara, the route is by Anhet, W. of the Ahaggar (Hoggar) massif to the Niger at Tosaye (Burem), some 200 m. below Timbuktu. What was regarded as the first section of the trans-Saharan was the line from Biskra to Tuggurt, opened in 1914. From Tuggurt to Tosaye by the route indicated is 1,470 miles. A line from Blida to Jelfa, on the way to Laghwat, was also built.

French projects to connect the Middle Niger with the ports of the Guinea Coast were hindered by the World War. The scheme was for railways from Dakar (Senegal), Konakry (French Guinea), Abidjan (Ivory Coast) and Kotonu (Dahomey) to be carried inland to the French Sudan (Upper Senegal and Niger colony), and there united by a transverse line. Political and economic considerations induced the French to neglect the Gambia river (as being British), the natural outlet for the French Sudan—the Gambia is navigable from the ocean by vessels drawing 13 ft. up to 153 m. inland. Of the lines proposed, that from Thies (Dakar) to Kayes, on the Senegal, begun in 1907, has a length of 682 m., of which about 100 m. remained to be built in 1920. The French Guinea line from Konakry reached Kurussa (365 m.) in 1910 and Kankan, in the French Sudan, 411 m. from Konakry, in 1915. This led to much of the trade of the countries in the Niger bend going to Konakry. The Ivory Coast railway from Abidjan, traversing a dense forest region, reached Buaké (193 m.) in 1913. No progress northward had been made by 1921. The Dahomey railway had reached Savé (162 m.) in 1912. All four lines are of the French standard West-African gauge, namely one metre. Besides the railways the French built many hundreds of miles of metalled roads, on which motor services connecting with the Niger countries were established.

In British West Africa local lines and extensions, on differing gauges, were built during 1910–20; there was no unity of plan such as marked the French programme in West Africa. The bridging of the Niger at Jebba, completed 1914, gave the chief Nigerian railway, that from Lagos to Kano (704 m. long), an uninterrupted service. In 1913 a new railway was begun from Port Harcourt, at the mouth of the Bonny river. It was completed to the Udi coalfields (151 m.) by May 1916. From Zaria, on the Lagos–Kano railway, a branch line, built across the tinfield area to Bukuru (143 m.), was completed in Dec. 1914. Surveys were made for an extension of the Port Harcourt–Udi line northward across the Benue river and thence north-west to a point, Kaduna, on the Lagos–Kano line. The building of this extension, some 450 m. in length, was begun in 1921. Motor services are maintained in connexion with the railways, which are Government owned.

In Morocco the French, from 1912 onward, built narrow-gauge railways for military purposes. By 1920 these connected (1) Sallee with Fez, and (2) Ujda, on the Algerian frontier, with Taza, while the section Fez–Taza was under construction. From Rabat via Casablanca another line was built to Marrakesh. The river dividing Sallee and Rabat was not bridged, but a ferry service was instituted. In 1918 the French Government decided to reconstruct the lines on the normal gauge. Up to 1921 no progress had been made on the Tangier–Fez railway. In North-East Africa the decade 1910–20 saw the completion of the railway from Jibuti to Addis Abbaba, the capital of Abyssinia.

The greatest mileage of railways built in the period under consideration was in South Africa (*see* SOUTH AFRICA). A line from Beira to the Zambezi (in construction 1920) gave Nyasaland direct access to the ocean. The Germans provided their South-West Africa Protectorate with an extensive system of railways. In Uganda the British built a short railway linking Jinja, on Victoria Nyanza, with

the first navigable stretch of the Nile, and during the World War a line connecting the Uganda railway with the Usambara railway in German East Africa was constructed.

The telegraphic system was greatly extended between 1910 and 1920, while from the first-named year gaps in the telegraph lines were increasingly filled by wireless telegraphy. The first wireless station in South Africa (at Durban) was opened in 1910. The Germans by the middle of 1914 had just completed powerful wireless stations in Togoland, South-West and East Africa. The French built stations in West and North Africa (Dakar, Algiers, etc.) and in 1920 had a trans-Saharan wireless service, there being two stations in the desert. Wireless stations in Egypt and the Sudan connected with Mombasa, Tabora and South Africa.

The World War gave a great impetus to aerial communications, and Cairo became the junction for services to and from Europe, Asia and the Cape. In 1919 an air route was laid out by British officers from Cairo to Cape Town, aerodromes being built at 24 different places. The distance by the air route was 5,206 m., compared with 6,823 m. by the Cape-to-Cairo land route. The first attempt to fly across Africa was made in Feb. 1920 by Dr. P. Chalmers Mitchell in an aeroplane chartered by *The Times*. At Tabora, a little over half way, the machine crashed (Feb. 27). The first to succeed in the enterprise were Col. Sir H. A. van Ryneveld and Maj. Sir C. J. Brand, of the South African forces. They reached the Wynberg aerodrome, Cape Town, after many delays and having had to use three machines, on March 20 1920. Their actual flying time from Cairo to Cape Town was 92 hours, 40 minutes. At the same time (Feb.–March 1920) French airmen, Maj. Vuilleman and a comrade, flew from Algiers across the Sahara to the Niger at Gao, and thence to Dakar. The first regular air service in Africa was established in 1921, with seaplanes along the Congo from Stanley Pool to Stanleyville, a distance of 1,000 miles.[1]

3. *History*.—A summary statement of recent territorial changes affords a guide to the course of events in Africa. In 1910 the British self-governing colonies of the Cape, Natal, Transvaal and Orange Free State were formed into the Union of South Africa, with a single government and one legislature. In 1911 a considerable area of French Equatorial Africa was transferred to the German protectorate of Cameroon, and in return Germany acknowledged a French protectorate over the greater part of Morocco, the protectorate treaty between France and Morocco being signed in April 1912. In Nov. 1912 a Franco-Spanish treaty defined the Spanish zones in Morocco. In 1912 also Italy annexed the Turkish *vilayets* of Tripoli and Bengazi (Cyrenaica), to which they gave the common name of Libya. In the same year the United States acquired financial control of Liberia, part of its hinterland having passed to France in 1910. In Dec. 1914 a British protectorate over Egypt was proclaimed. In June 1919, by the Treaty of Versailles (which came into force Jan. 10 1920), Germany renounced possession of all her oversea protectorates in favour of the principal Allied and Associated Powers. These protectorates were placed under mandatories. The Union of South Africa became mandatory for German South-West Africa, which her troops had conquered in 1915. It was renamed the South-West Protectorate. Togoland was divided between France and Great Britain (it had been conquered by British and French troops in Aug. 1914). France became the mandatory for Cameroon, but a small portion was transferred to (British) Nigeria. Cameroon had been conquered by Anglo-French forces, in 1915–6. Britain became mandatory for German East Africa, renamed the Tanganyika Territory. A small fragment (the Kionga triangle) of German East Africa was, however, added to Portuguese East Africa, and the greater part of the provinces of Ruanda and Urundi to the Belgian Congo. German East Africa had been conquered, as to the greater part in 1916, by British and Belgian troops. An Anglo-French convention of Sept. 1919, ratified in 1921, settled the boundary between Wadai and Darfur, which had been in dispute since 1899. In 1920–1 Italy gained additions to Tripoli and Cyrenaica by arrangements with France and Great Britain; also the promise of an addition to Italian Somaliland at the expense of British East Africa. British East Africa, up to then a protectorate, was in 1920 annexed to the British Crown and renamed Kenya Colony.

As a result of these changes Africa was divided among the following Powers, territories governed under a mandate being reckoned in the possessions of the Powers named:—

	sq. m.
Great Britain	4,364,000[2]
France	4,200,000
Portugal	788,000
Italy	650,000
Spain	140,000[3]
Belgium	930,000
Liberia	40,000
Abyssinia (Independent)	350,000

These figures give a total of 11,462,000 sq. m. as the area of Africa. In the absence of definite surveys of large areas of the continent this may be regarded as a close approximation to accuracy. In 1914 the German possessions in Africa had an area of approximately 1,030,000 sq. m.; the Turkish possessions (not reckoning the legal suzerainty it possessed over Egypt) an area of some 400,000 sq. miles.

The extinction of Turkish rule in North Africa had long been foreseen and was no matter for regret. It ended a connexion which had lasted five centuries and had been almost wholly evil in its effects. German sovereignty in Africa had dated from 1884 only and had been rapidly enlarged. Endeavours further to extend it had been a prominent factor in German policy for a decade before the World War began, and closely affected very large areas of Africa. Germany desired to secure a footing on the African coast of the Mediterranean and a port on the Atlantic coast of Morocco. These desires conflicted with Italian and French ambitions, and in 1911 the issue on both points was decided against Germany. As to Morocco the Franco-German convention of Feb. 9 1909 had recognized the privileged position of France in Morocco, but not a French protectorate over that country, and the sending of the German gunboat "Panther" to Agadir in July 1911 was a protest against what Germany considered an unwarranted extension of French influence in Morocco, and an intimation that if German treaty rights in Morocco were to be renounced France must make compensation. According to Prince Bülow, Germany—in 1911—"never had any intention of taking possession of any part of Morocco . . . England and Spain, besides France, would have opposed us there" (*Imperial Germany*, 1913 ed.). Although this statement may be an after-the-event reflection the intervention of Britain on the side of France was decisive. Germany withdrew her opposition to the establishment of a French protectorate over Morocco, and accepted compensation in Central Africa. While the Franco-German negotiations were still in progress, Italy, by abruptly declaring war on Turkey and invading Cyrenaica and Tripoli, deprived Germany of her last opportunity—short of war—of gaining a footing in the Mediterranean.[4]

The alternative scheme to territorial acquisitions in North Africa which Germany had prepared were indicated in a note addressed to France on July 15 1911, during the Agadir crisis. Germany then proposed that France should cede the greater part of the coast and the interior of French Equatorial Africa as far as the Sanga tributary of the Congo river, and further renounce in favour of Germany her right of preëmption over the Belgian Congo. These proposals Germany was compelled greatly to modify, but by the convention of Nov. 4 1911 large tracts of French territory were added to Cameroon. On the south these additions made Spanish Guinea an enclave

[1] A mail air service from Toulouse to Casablanca had been instituted in 1920.

[2] Including Egypt and the Anglo-Egyptian Sudan.

[3] Including the Spanish zones in Morocco.

[4] In view of the position publicly assumed by Germany in 1898 of friendship to Moslems in general and to Turkey in particular, Germany had not sought direct rule over the Ottoman provinces in question. Turkish sovereignty was to be respected, but an Austro-Hungarian chartered company had been formed under German auspices for the exploitation of Tripoli and Cyrenaica, and under the charter Austrian (in effect German) authority would have been imposed upon those *vilayets*. Italy, however, ever since the establishment of the French protectorate over Tunisia in 1881, had "ear-marked" Tripoli and Cyrenaica for herself. See the *Memoirs of Francesco Crispi* (London, 1914) and H. H. Johnston in *Geog. Jnl.* (vol. 44, pp. 280–1).

in Cameroon and gave Germany the southern shores of the Muni estuary. In the east the additions to Cameroon included two tongues of land which gave the protectorate direct access to the Congo river and its great northern tributary the Ubangi.

The *Mittel Afrika* scheme foreshadowed in 1911 aimed at securing Germany's supremacy, primarily economic and ultimately political, in central equatorial Africa. The aim was to reserve the Belgian Congo, Angola and Mozambique N. of the Zambezi as a German sphere and thus to link up Cameroon with the South-West and East Africa protectorates. German industries had need of the raw material tropical Africa produces, and moreover southern Angola was a good field for European settlement. British statesmen were not unfavourable to German expansion in equatorial Africa—so long as it was confined to the economic sphere. In 1898—the year of Fashoda—Mr. A. J. Balfour and Count Hatzfeldt had concluded an agreement which divided Angola and Mozambique into zones in which Britain and Germany respectively were to give financial and economic assistance to the Portuguese. This agreement was capable of various interpretations and in the following year (1899) another agreement, known as the Treaty of Windsor, renewed the ancient Anglo-Portuguese alliance, the object being to reassure Portugal that the Balfour-Hatzfeldt agreement was not in derogation of her sovereign rights in Africa. Neither the agreement with Germany nor that with Portugal was published.

After the settlement of the Morocco crisis of 1911 Germany endeavoured to come to a further understanding with Great Britain. Negotiations in regard to the Portuguese colonies in Africa were reopened by Baron Marschall, then ambassador to Britain, and were energetically taken up by Prince Lichnowsky, who came to London as ambassador in Nov. 1912. A new agreement was drawn up and its terms fixed. It affirmed the intention of the signatories to respect the sovereign rights of Portugal and went on to delimit the region in which each party was, as far as the other party was concerned, to have a free hand in respect to economic development. By Prince Lichnowsky, and by the German Foreign Office, the new agreement was looked upon as a stepping-stone to political rights in the regions concerned. By this agreement the whole of Angola up to long. 20° E. became a German sphere, together with the cocoa-producing islands of San Thomé and Principe. On the E. coast the whole of Mozambique province N. of the river Likungo also became a German sphere.[1] Originally Belgian Congo was, according to Lichnowsky, to have been included in the agreement, but Germany refused the offer "out of alleged respect for Belgian sensibilities."

In Aug. 1913 the agreement was ready for signature. But Sir Edward Grey, then British Foreign Minister, made it a condition of signing that the 1898 and 1899 agreements as well as the new agreement should be made public, with the obvious object of again reassuring Portugal. The German Foreign Office objected to publication, as detrimental to negotiations for concessions then proceeding with Portugal, and, as Herr von Jagow (then Foreign Secretary) said, because the German press would regard the terms of the Treaty of Windsor and the Lichnowsky agreement as contradictory. Von Jagow said that publication of the agreement would be better delayed until the Bagdad railway treaty—which was looked upon as a genuine triumph for Germany—could also be published. In July 1914 German consent to the publication of the agreement was given—but before the document could be signed the World War had begun.

During the period of these Anglo-German negotiations the French in Morocco, under Gen. Lyautey as resident general, had adopted both a bold and conciliatory policy and had won the respect of the majority of the Moors; the French also steadily developed their West African colonies and had brought under control the region between Lake Chad and the Nile basin. In the German colonies there was likewise considerable development, notably in the building of railways. It was a period too of material development in the British colonies and of prosperity in Egypt and the Sudan, accompanied in Egypt by manifestations in favour of self-government. In South Africa the alliance of Dutch and British, which had brought about union, had been followed by a reaction among a section of the Dutch, but the majority of the people followed the Prime Minister, General Botha, and his colleagues in their loyal adherence to the British connexion. When the World War broke out it was found that the German authorities in South-West Africa had maintained for years clandestine relations with a number of Boer leaders and that they counted, at the least, on South Africa's neutrality in the war; Germany had also established relations with elements in North Africa inimical to France and Great Britain.

But the British command of the sea rendered it impossible when hostilities began for Germany to succour her colonies. And this led to proposals for neutrality in various parts of Africa. The first such proposal was made, on instructions from Berlin, by the acting-governor of Togoland to the French and British authorities on Aug. 4 and 5, reasons of humanity and the presumed need of the white races to exhibit solidarity in face of the negroes being alleged. This proposal, purely local in scope, was not entertained (*see* TOGOLAND). Later in the month—Aug. 23—Germany made an offer of neutrality in the conventional basin of the Congo as defined in Article I. of the Act of the Berlin Conference of 1884–5. The Congo Free State, in accordance with the permission given by Article X. of the Act, had proclaimed its perpetual neutrality, and when the Free State became a Belgian colony the obligation of neutrality was retained. No other state exercising jurisdiction within the conventional basin of the Congo had, however, exercised the option given by Article X. of proclaiming its neutrality within that area, which included besides Belgian Congo about half of French Equatorial Africa, a third of Cameroon, all German East Africa, all British East Africa, all Uganda, all Nyasaland, Mozambique N. of the Zambezi, a small part of Northern Rhodesia and the northern part of Angola. Belgium had desired to preserve neutrality in the Congo. At the outbreak of the war M. Fuchs, governor-general of Belgian Congo, had been instructed to observe a strictly defensive attitude, and on Aug. 7 M. Davignon, then Belgian Foreign Minister, asked the British and French Governments if they intended to proclaim the neutrality of their territories in the conventional basin of the Congo. The bombardment of Dar es Salaam by British warships on Aug. 8 was a sufficient demonstration of the British attitude; but at first the French Government seemed disposed to entertain the proposal; so the Belgian minister in Paris informed M. Davignon on Aug. 9. But the French commander in Equatorial Africa had opened hostilities on Aug. 6, and on Aug. 17 Comte de Lalaing, Belgian minister in London, informed M. Davignon that neither Great Britain nor France could adopt his suggestion.

Hostilities in the conventional basin of the Congo had thus been proceeding for over two weeks when Germany made her neutrality offer; on the day before it was made the Germans in East Africa had committed the first act of war in the Belgian Congo by bombarding Lukuga, a port on Tanganyika. The German *démarche* was made by Herr Zimmermann, Under-Secretary in the Foreign Office, to Mr. Gerard, the American ambassador in Berlin, in a note which asked the aid of the United States to procure the neutralization of the conventional basin of the Congo. In a later note, dated Sept. 15 1914, Herr Zimmermann stated that Germany's object was "to prevent an aggravation of the war which could serve no purpose," which was not the view of Von Lettow Vorbeck, the German commander in East Africa, "while prejudicial to the community of culture of the white race." The Department of State at Washington confined itself to forwarding the German notes, without comment, to the governments concerned. Spanish aid was also sought by Germany. But France and Great Britain refused to entertain the proposals, while, the Belgian Congo

[1] The Likungo lies about 120 m. N. of the Zambezi. The Zambezi valley and all the territory S. to and including Delagoa Bay was reserved as the British sphere. Britain already had the right of preëmption over Delagoa Bay.

having been attacked, M. Fuchs had been given permission, on Aug. 18, to aid the French in the Cameroons campaign. The efforts of Dutch nationalists in South Africa to save German South-West Africa from invasion were equally fruitless.

In process of time the whole of Africa, except Abyssinia and the Spanish protectorate, was involved in the war (for the operations see the articles on the various countries). The conquest of the German colonies was foreseen in the negotiations which preceded Italy's entry into the war, and Article XIII of the agreement signed in London on April 26 1915 between France, Russia, Great Britain and Italy, said:—

In the event of France and Britain increasing their colonial territories in Africa at the expense of Germany, those two Powers agree in principle that Italy may claim some equitable compensation, particularly as regards the settlement in her favour of the questions relative to the frontiers of the Italian colonies of Eritrea, Somaliland and Libya, and the neighbouring colonies belonging to France and Great Britain.

At a meeting of the Supreme Council at Versailles on May 7 1919 it was agreed to form an inter-Allied Committee to consider the application of Article XIII., which had already been the subject of negotiations. Italian desires went beyond the readjustment of frontiers. In north-east Africa she sought a position which would give her all the seaward approaches to Abyssinia. In particular Italy desired to acquire Jibuti, the port of French Somaliland, whence a railway ran to Addis Ababa. This desire was intimated to France in the negotiations preceding the signing of the London agreement of 1915. But Jibuti was the only French port on the Suez Canal route to the East and to Madagascar, as well as the only approach to Abyssinia France possessed, and she declined to entertain proposals for its surrender. Italy, however, obtained from France a welcome rectification of the Tripoli–Tunisia frontier, besides valuable railway and commercial privileges in Tunisia. The claim to extend the hinterland of Tripoli to Lake Chad was refused. With Great Britain the negotiations were prolonged; the British Government, however, assented in 1919 in principle to a considerable readjustment of territorial claims in the Cyrenaican–Egyptian hinterland, that is in those regions of the Libyan Desert in which lay Kufra and other Senussi strongholds. The oasis of Jarabub was assigned to Italy. In East Africa the British offered an addition to Italian Somaliland by the transfer to it from Kenya Colony of the western part of the valley of the Juba—a rich cotton-growing area—together with the port of Kismayu. This offer was accepted in Sept. 1919, but the Italians desired a larger concession and this led to delays in the final settlement. The proposal to transfer Kassala from the Sudan to Eritrea was not entertained. Meanwhile the area administered by the Sudan Government had been enlarged by the conquest of the tributary sultanate of Darfur in 1915.

The distribution of the German colonies after the war has already been stated. The change of masters was readily accepted by the natives. The war itself stimulated trade in various parts of Africa and led to a development of communications (see page 67, *Communications*).

Politically the greatest movements in Africa in 1919–21 were the continuance of the separatist campaign by the Dutch Nationalist party in South Africa, and the insistent demand of the Egyptians for independence. These movements are described in the articles SOUTH AFRICA and EGYPT.

Another subject which raised large issues was the position of Indians in South and East Africa, but it was of less importance than the growth of race consciousness among the negroes. Increase of education and of Christianity, the employment of large numbers of Africans in industries, and the lessons taught by the World War, were among the factors which intensified the feeling of racial unity, and led to manifestations of a new anti-white movement—a movement different from the simple objection to interference by Europeans or Arabs previously displayed. The new movement had a consciousness of the need of self-development and progress. Not all the ferment among the negroes was however anti-white, nor was there by 1921 any clear indication what form negro nationalism would ultimately take.

AGA KHAN III. (1877–), Indian Moslem leader (*see* 1.363). During 1910–21 the Aga Khan's widening influence both on Indian and international affairs was shown in various directions. He had headed the Moslem deputation in 1906 to the Viceroy, Lord Minto, which submitted the case for encouraging abandonment of the studied aloofness of their community from Indian political life; and he was president of the All-India Moslem League thereupon formed during its first constructive years. He initiated the fund, and personally collected more than Rs.30 lakhs, for raising the Mahommedan college at Aligarh to university status, which was effected in 1920. In the immediate pre-war years he did much to soothe Indian Moslem sentiment in respect to the Turco-Italian and two Balkan wars. He was touring amongst his followers in East Africa when the World War broke out, and immediately cabled to the *jamats* or councils of the millions of Ismailiahs within British territories and on their borders directing his followers to place themselves unreservedly at the disposal of the British authorities. Both in East Africa and on arrival in England he pleaded for combatant participation in the war, but Lord Kitchener reserved him for services no one else could render. When Turkey was drawn into the struggle the Aga Khan issued a stirring manifesto showing that the Allies had no overt designs on Islam, and calling upon the Moslems of the Empire to remain loyal and faithful to their temporal allegiance. His immediate followers provided a solid phalanx of whole-hearted support of Britain, which had a most steadying influence in sterilizing the efforts of impatient headstrong elements. Secret missions of great diplomatic importance in Egypt, Switzerland and elsewhere were entrusted to His Highness, and enemy anger found scope not only in bitter newspaper attacks but in designs upon his life. His great influence was reënforced by his close and intimate contact with leading Allied statesmen and the breadth and liberality of his outlook on the problems of reconstruction. His remarkable study of Indian and Middle Eastern affairs in *India in Transition* (1918) was not without considerable effect in the final shaping of reforms under the India Act of 1919, and was consistent in broad principle with his post-war criticisms of the British Government's Mesopotamian and Arabian policy.

The Aga Khan laboured unceasingly to secure mitigation of the Allied terms toward Turkey, and joined in many representations, public and private, both at the Peace Conference and subsequently, as to the immense importance to Great

(F. H. Br.)

AGLIARDI, ANTONIO (1832–1915), Italian cardinal and diplomatist (*see* 1.377). Noted for his strongly patriotic sentiments, he actively opposed the Temporalist tendencies which prevailed at the Vatican during a part of the pontificate of Leo XIII. At a time when clerical influences in France aimed at a restoration of the Temporal Power, Agliardi was frankly favourable to the Triple Alliance as the best guarantee of Italy's territorial integrity, and he eventually succeeded in convincing the Pope of the hopelessness of his schemes. With Leo's subsequent social-Catholic activities he was in hearty sympathy, and contributed much to their success. He enjoyed the personal friendship of many of the most eminent men in Italy, including Luigi Luzzatti, Antonio Salandra and the Marquis di San Giuliano. He died in Rome March 19 1915.

AGRICULTURE (*see* 1.388). In the separate articles on different countries of the world, their agricultural progress between 1910 and 1920 is dealt with. Here will be considered (1) the progress of scientific research generally, (2) the agricultural administration and regulations in the United Kingdom, and (3) the developments in the United Kingdom during the World War. Developments in the United States 1910–21 are described under the heading *Agriculture* in the article UNITED STATES.

I. PROGRESS OF SCIENTIFIC RESEARCH.

During 1900–20 scientific research upon the soil was in the main directed to two sets of phenomena—the interaction of the various groups of organisms living in the soil, and secondly the relation of the various soil constituents to water as a means of interpreting the physical behaviour of the soil under cultivation.

Soil Research.—Dealing first with the latter question, it has long been obvious that the crude view which regards the soil as a mere mechanical foundation for the plant containing a certain amount of plant food—nitrogen, potash and phosphoric acid determinable by analysis—must be abandoned. Infertile soils disclose in the surface layer sufficient plant food for a hundred full crops, and even the later modification of the hypothesis which laid stress not on the "total" plant food in the soil but on the amount that was "available," *i.e.* soluble in some dilute medium such as carbon-dioxide-charged water and a solution of an organic acid akin to the cell sap of the plant, failed to provide a means of measuring fertility by chemical analysis. It was the failure of this chemical theory of the soil that led the American investigators, Whitney and Cameron, to propound the view that what really matters in the soil is its water relationships. The plant's roots feed in the soil solution, the liquid medium held on the surface of and between the soil particles by surface tension, and as this solution is always saturated, *e.g.* with phosphoric acid and potash of which any soil contains more than the soil solution is capable of dissolving, then the actual amount of these constituents in the soil (above a certain very low minimum) and the extra amount supplied by fertilizers are matters of indifference. Apart from some other factors, it is the water supply that determines the growth of the plant and therefore the fertility of the soil. In its turn this hypothesis breaks down, because it takes too simple a view of the process of solution in the soil, which it regards as a mixture of definite compounds possessing a definite solubility like sodium chloride or other inorganic salts. Actual experiment showed that whenever soil extracts were prepared from soils of different fertility or when even the solutions actually existing within the soils could be removed by mechanical means, they displayed a varying concentration in phosphoric acid and potash. Moreover the growth of plants in such extracts [illegible] within limits proportional to the [illegible] water soil drain through the soil [illegible] the rate at which [illegible] portions of water will be removed from it by evaporation under constant conditions, shows that the soil does not behave as if it were a mixture of mere rock particles of various grades of fineness. An artificial soil built up of particles of ground quartz of the same order of sizes as the soil behaves quite differently towards water, so again does a soil that has been ignited to a red heat. In the natural soil a number of the particles, especially those of the smallest size, exhibit colloid properties, which roughly means that they have a special power of holding water on their surfaces more and more tightly as the amount of water diminishes, and also of holding and withdrawing from solutions, the ions, sometimes basic, sometimes acid, of salts. These colloids are probably the particles of compound aluminium silicates resulting from the decomposition of the felspars in the original rock basis; they are akin to the zeolites which can be found in a pure state. The humus or organic matter of the soil is also largely colloid, but the inorganic colloids themselves will account for most of the properties of the soil.

As regards the water itself, the colloid theory explains certain facts which had much occupied the attention of the American investigators who have been studying the relation of plants to soil under arid conditions as a means of extending cultivation upon the bad lands. Sachs had long ago shown that a plant would begin to wilt and be unable to take water from the soil before the soil was absolutely dry, again that a clay soil would hold water against the plant much more strongly than a sandy soil, wilting occurring when the clay soil has still 8% or more of water in it, whereas the sand will lose water down to 1% before the wilting begins. Various attempts have been made to correlate the "wilting coefficient" of the soil, *i.e.* its proportion of moisture when wilting sets in, with the "hygroscopic moisture," *i.e.* the amount of water a dry soil will absorb when in contact with a saturated atmosphere, and with the amount of water the soil holds when wetted and allowed to drain. But none of these conceptions mark any change of state; for example the curve expressing the rate at which evaporation will take place from soil is a perfectly smooth one without any discontinuities, and the points defining the wilting coefficient or the hygroscopic moisture are only particular positions of equilibrium between the water-holding power of the soil particles and the external set of forces tending to remove water. In the same way the distinction between the water held by the colloids and the "free water" in the soil, the latter being regarded as something different in kind and sharply marked off from the colloid water, cannot be maintained. The colloid "gels" must be regarded as imbibing water and exercising some attractive action on all the water in the soil, though that attraction is infinitesimal when the soil is saturated and only becomes a measurable force when the water has shrunk to small proportions.

The colloids that hold water in the soil are also the agents which control the composition of the soil solution upon which the plant feeds. If the soil colloids are brought into contact with a solution of any of the fertilizer salts (except the nitrates with which the action is very slight) there is an instantaneous absorption of ammonia, phosphoric acid or potash as the case may be, that is never complete, the extent being determined by such factors as the relative mass of the soil and the fertilizer, the concentration of the solution and the nature of the accompanying ions, *e.g.* carbon dioxide in the soil solution. Speaking broadly, a fertile soil is one possessing a high absorptive capacity, that is as it were pretty fully charged, so that the equilibrium with the soil solution is mobile and the soil colloids part freely with their nutrients to the solution as its strength is reduced through withdrawals by the plant's roots. The analytical methods which attempt to determine say the "available" phosphoric acid by attacking the soil with weak acids really determine something much more complex in which the absorptive power of the soil plays a part. The acid, whatever its nature, first dissolves all the phosphoric acid, and then there is a reabsorption, the amount of which is conditioned by the nature and strength of the acid employed. Thus the result obtained is an empirical one, valid only for comparisons of soils of similar type and constitution, to which limited degree it is of service.

Living Organisms.—The study of the living organisms of the soil has resulted in some reconsideration of the views formerly held as to the relative importance and function of the different groups. Among the earliest of the organisms associated with the soil to be specifically studied were those concerned with the process of nitrification and responsible for the conversion of ammonia (resulting from the breaking down of organic compounds of nitrogen by other bacteria) first into nitrites and then into

nitrates. It was held that as plants (other than the legumes) practically take in all their nitrogen as nitrates, then the rate of nitrate-making or the nitrifying power of a soil would be on one side at least a measure of its fertility. In the course of the experiments on the partial sterilization of soil by heat or antiseptics it has become apparent that the nitrification organisms are very susceptible and may be killed off while the ammonia-making organisms are still active. Again acid soils have been found in which nitrates are not produced. Yet in such soils plants grow freely, taking in their nitrogen as ammonia, not as nitrate. It becomes clear that nitrification is only the end process, and the rate at which it will proceed is determined in a normal soil by the rate at which the other organisms supply ammonia. This is seen from the fact that nitrates will heap up in the soil, whereas the ammonia remains comparatively constant at a very low level provided that the soil is normal and nitrification is going on.

For a long time the only organisms capable of "fixing" nitrogen, *i.e.* bringing the free gas from the atmosphere into combination, were the so-called "nodule" organisms (*Pseudomonas radicicola*) discovered by Hellriegel and Wilfarth, which live in symbiosis with the leguminous plants. More recent investigations have discovered methods whereby these organisms can be grown and made to fix nitrogen independently of a host plant, and have also cleared up the forms in which they exist in the soil and find their way into the roots of the leguminous plant. The attempts to improve the growth of leguminous crops by inoculation with strains of the particular organism have not been attended with any practical success, though soils, generally of the new or reclaimed order, destitute of the nodule organism, can now be effectively inoculated and thereby made to grow good crops of legumes, provided always that the soil is first made a fit medium for the organism by a supply of lime and appropriate mineral manures. Without this preliminary acid heath or peat soils would neither support the nodule organisms nor the leguminous crops and inoculation would be of no avail. But as "fixers" of nitrogen apart from the leguminous plants *Pseudomonas radicicola* is ineffective compared with a widespread group of organisms isolated by Beijerinck, to which he has given the name of *Azotobacter*.

Azotobacter.—These organisms, found in both virgin and cultivated soils from all parts of the world, are comparatively large oval bodies 4 to 5 μ in length and 3 μ in width, which differ from normal bacteria in containing glycogen and act as powerful agents for the oxidation of the sugars and other carbohydrates. From the carbohydrates they produce in the main carbon dioxide and water, but also small quantities of organic acids and of a characteristic deep brown pigment. It is by means of the energy derived from the oxidation that they are able to bring nitrogen into combination and the nitrogen fixed under favourable laboratory conditions may amount to 1% of the carbohydrate oxidized. To be effective *Azotobacter* requires certain conditions—a neutral medium with calcium carbonate present to neutralize the acids produced, for which reason the organism is generally absent from acid soils, also the presence of such nutrients as phosphoric acid and potash, and finally a favourable temperature. It has been found at Rothamsted that a soil will accumulate nitrogen, as evidenced by an increased crop, after the application of starch or sugar, carbohydrates containing no nitrogen, if these materials are mixed with the soil in the early autumn when the land is still warm and *Azotobacter* is active. On the other hand spring applications of carbohydrates are followed by a diminished crop, because at a low temperature other organisms in the soil which are consumers of combined nitrogen, attack the carbohydrate and by their multiplication withdraw some of the soil nitrogen from circulation and so reduce the supply for the crop.

The great significance of these observations of the mode of action of *Azotobacter* is that they afford a solution of the problem of how the great stocks of combined nitrogen came to be accumulated in virgin soils, especially in certain black soils such as occur on the prairies and in the Canadian North-West. Of itself the mere growth and dying down of vegetation for however many years repeated, could not add to the stock of combined nitrogen in the soil. The plant itself fixes no nitrogen, but only draws upon the capital in the soil, restoring whatever it took out when the vegetation is allowed to die back to the soil without loss. But the falling vegetation contains carbohydrates derived from the air and if they are added to a soil containing *Azotobacter* under conditions favourable to its growth, the carbohydrate supplies the energy whereby the *Azotobacter* can fix some more nitrogen from the air and add to the stock in the soil. In this way the annual cycle of vegetation when the leaves fall back to the soil can result in a yearly accretion of nitrogen which in time may amount even to the remarkable accumulation found in the deep black soils of Manitoba and similar "steppe" lands, soils that are invariably found to be well supplied with carbonate of lime and also to contain the *Azotobacter* organism. The clue to this interpretation of the accumulation of nitrogen in virgin steppe and forest soils was derived from the examination of the soils of the wheat field at Rothamsted. The soil of the unmanured plots which has been in arable cultivation for over half a century shows a steady decline in the amount of nitrogen it contains, a decline which is approximately equivalent to the nitrogen which is known to have been removed in the crops harvested year by year. Doubtless the soil has suffered other losses of nitrogen by drainage, removal of weeds, etc., that cannot be estimated, but the analysis of the soil shows that any recuperative processes which may have been at work restoring nitrogen to the soil have only been able to repair these minor losses but not to restore any of the nitrogen removed in the crops. A portion, however, of the same plot was allowed to go to waste, *i.e.* it was allowed to cover itself with a natural vegetation of weeds and grasses, which were neither cut nor grazed but allowed to die back to the soil. After 30 years an examination of the soil of this wilderness showed it had been accumulating nitrogen at the rate of nearly 100 lb. per ac. per annum, the greater part of which must have been due to the action of *Azotobacter* working upon the carbonaceous matter supplied by the decaying vegetation reaching the soil in the autumn and winter.

On the arable land where the vegetable matter reaching the soil is minimal, only the roots and stubble of the crop, there is a steady loss of nitrogen; on the wilderness which may be compared to a natural prairie, the return of the vegetation to the soil causes nitrogen to accumulate not because of the nitrogen contained in its material, but because its carbonaceous matter supplies the energy whereby the *Azotobacter* fixes nitrogen. The *Azotobacter* group of organisms, though not the only ones capable of bringing free nitrogen gas into combination, constitute the group which has played the fundamental part in building up not merely the vegetable soil but the whole substratum of organic life in the world.

Soil Protozoa.—The outlook on the organisms in the soil has been entirely changed since Russell and Hutchinson showed the part played by the protozoa in limiting the development of bacteria in the soil. The soil protozoa, which are large, definitely animal organisms of varied character—amoebae, ciliates and flagellates—exist in large numbers in all cultivated soils, and as they feed upon bacteria, any conditions which encourage the development of bacteria by increasing their food-supply stimulate the multiplication of the protozoa which thereby put a check to the increase of the bacteria. Thus normally the number of bacteria in a soil, however rich and favourable to bacterial development the conditions may be, does not pass a certain limit because it is kept in check by the increasing number of the protozoa. As the fertility of the soil among other things depends on the rate of production by bacteria of ammonia and nitrates from the nitrogenous residues in the soil, the fertility of the soil is also limited by the presence of the protozoa. Certain processes of partial sterilization of the soil, such as heating to the temperature of boiling water or even to 170°F. or again treatment for a time with some antiseptic, *e.g.* chloroform or toluene vapour, effects a selective destruction of the soil organisms. The protozoa are almost entirely killed off, but many groups of bacteria, notably, the ammonia-makers, resist destruction though they may be reduced in numbers. But if after treatment the treated soil is placed under normal conditions for growth, the bacteria that remain multiply with great rapidity and rise to a level of numbers and activity they were unable to attain before, because now the protozoal check to their multiplication has been removed. In consequence the fertility of the soil is greatly increased; in fact the yield from a given soil may be doubled. This discovery suggests immense potentialities of increased production from the land but as yet it has not been found possible to apply the method of partial sterilization to ordinary field soils in the open. Heating would be inordinately expensive and the difficulty is to find an antiseptic that combines cheapness with the right degree of

volatility and stability against the attack of bacteria. In greenhouses, however, where the soil soon becomes "sick" through the excessive development of protozoa under the favourable conditions of moisture, temperature and manurial enrichment, the sterilization of the soil by heat has been worked out as a commercial process and is now part of the routine of all progressive cultivators under glass.

Microfungi.—Great as is the attention that is now being given to the soil organisms in all agricultural laboratories there would appear to be room for more work upon one group—the microfungi, of which there is a large flora in the soil.

It has been shown that when from one cause or another a soil becomes acid, many bacteria concerned in the decay of vegetable matter are entirely inhibited and may disappear. Fungi instead take up the work, but the broad character of the process thereby changes, the vegetable matter is not burnt away as carbon dioxide but in part accumulates in the form of peat. The formation of a peaty material is in fact a concomitant of an acid reaction in the soil and the activity of microfungi rather than of bacteria, and this generalization fits in with many observations of the character of peat deposits.

Often trees are found at the base of these beds where trees no longer grow; and it may be surmised that the trees grew on the original neutral land surface when it became fit for vegetation after the close of the glacial epoch. That soil being of a non-calcareous nature gradually accumulates acids arising from the decay of the vegetation falling upon it, whereupon under the prevailing climatic conditions the further vegetable debris reaching the soil began to form peat. This accumulation of peat in its turn brought about the death of the forest.

Nitrogen.—During 1910–20 agriculture received great benefit from the working out of processes on a large scale for bringing nitrogen into combination, processes which thus supplement the comparatively limited sources of nitrogen compounds afforded by the Chile deposits of nitrate of soda and the ammonia which is recovered as a by-product from the distillation or combustion of coal.

Prior to the World War two processes had been established commercially. At Notodden in Norway air is driven into a specially formed electric arc which results in the combination of nitrogen and oxygen so that the issuing gases contain about 1·25 % of oxides of nitrogen which are then absorbed by passing up towers where they meet an absorbing stream of water or milk of lime. The product, nitrate of lime, contains about 13·5 % of nitrogen, and is a most valuable fertilizer, quite as effective as nitrate of soda and on some soils more suitable.

At about the same time as synthetic nitrate of lime was introduced, another nitrogenous fertilizer began to be manufactured on a large scale, calcium cyanamide or nitrolim. The body arises from the combination which ensues at a temperature of about 600° C. between calcium carbide and pure nitrogen gas under slight pressure, with the resulting formation of a compound which in the soil decomposes mainly into ammonia and calcium carbonate. Cyanamide as a fertilizer requires a certain amount of care in use and on the majority of soils has not proved so effective as nitrate of soda or sulphate of ammonia. Its manufacture, however, received an immense impetus during the World War, as it was the simplest and most readily available process for bringing nitrogen into combination, from which by further steps ammonia and then the nitrates and nitric acid required in explosives could be obtained. The United States and many European countries have immensely developed the manufacture of cyanamide, which must in future be available as fertilizer either used directly or after prior conversion into some convenient compound of ammonia.

The war period was also marked by the development on a gigantic scale of a new process, which had only been finally worked out to the manufacturing stage in Germany in 1913—the Haber process of bringing nitrogen and hydrogen into combination as ammonia. In the presence of a suitable catalyst of activated iron these elements will unite at pressures of 250–300 atmospheres and a temperature approaching 600° C. to the extent of 8 % or so of the mixed gases. The ammonia can be removed and the remaining gases passed round again into the catalyser. Great as are the difficulties of working at these temperatures and pressures the Haber process is cheap in power and materials. It was the mainstay of the supply of combined nitrogen for explosives to Germany during the war, and should become a most important future source of fertilizer to the agriculturist.

During the war the demand for nitrogenous fertilizers greatly increased in all countries; the United Kingdom for example increased her consumption of sulphate of ammonia from 60,000 tons to 269,000 tons per annum, part of this being of course substitution for the pre-war use of 80,000 tons of nitrate of soda, which was no longer available. Potentially, however, the establishment of so many war plants for the manufacture of synthetic nitrogen products has increased the supply of nitrogen available as may be seen from the following table:—

	Metric Tons of Nitrogen.		
	Output 1912	Output 1917	Productive Capacity 1920
Chile Nitrate . .	411,329	465,000	471,000
Ammonium sulphate (by-product) . .	272,007	340,000	413,000
Cyanamide. . .	22,435	190,000	325,000
Haber process . .	....	100,000	308,000
Arc process . .	9,907	27,000	33,600
	715,678	1,122,000	1,550,600

It should be noted, however, that the 1920 figures are not actual but only potential supply, if existing plants are worked up to their capacity.

Potash.—As the only extensive potash deposits in the world that had been commercially developed—Stassfurt and Alsace—were in German hands, there was during the war a great shortage of potash fertilizers outside central Europe. Great efforts were made to develop processes for the extraction of potash from felspars and other natural sources, but without much success.

The only method which proved of value was the discovery made in the United States that the dust which accumulates in the flues through which the gases from blast furnaces are led contains a not inconsiderable amount of potash in a readily soluble form, one-half indeed consisting of sulphates and carbonates soluble in water. Different grades of flue dust can be collected: the finest is a cream-coloured material containing as much as 60 % of potash. The dust was collected and used for agricultural purposes during the war though only some 15,000 tons per annum were obtainable in Great Britain. It is now worked up for industrial purposes, but the output of potash salts from this source cannot exceed a few thousand tons per annum in the United Kingdom. The supply of potash salts for agricultural purposes since the war has been entirely changed by the transfer to France of the Alsatian deposits which occupy an area of some 77 sq. m. between Mülhausen and Colmar in Alsace. This deposit consists of two beds, the upper about 4 ft. thick, the lower about 11½ ft., which form practically unbroken strata at an approximate depth of 1,800 ft. and present no difficulties in mining. The material is very uniform in composition, consisting in the main of sylvinit, mixed chlorides of potassium and sodium, containing about 20 % of potash reckoned as K_2O. It can be used for agriculture in its crude state and though the development of the field is still very incomplete the former German monopoly of potash supplies is thereby broken down. Another extensive deposit is known in Spain, but it has not reached the stage of commercial development and is generally considered to be controlled by the German company which works the Stassfurt deposits.

Superphosphates.—During the war the manufacture of superphosphate in the United Kingdom was considerably restricted, on the one hand by the withdrawal of sulphuric acid for the manufacture of explosives, and on the other by the shortage of tonnage for the importation of phosphate rock. American supplies were completely cut off and receipts from the North African deposits fell to something like 500,000 tons per annum. In consequence British farmers were compelled to resort mainly to basic slag of which this country produced about 400,000 tons per annum, though prior to the war only some 280,000 tons had been consumed by British agriculturists. With the extended programme of arable farming the demand for phosphatic fertilizers was greatly increased and the whole of the basic slag produced at home was absorbed, though the output was increased to as much as 565,000 tons from the year ending May 1919. Unfortunately this increase in amount was accompanied by a decline in character, owing to changes in the processes generally adopted for making steel.

The Bessemer process has been almost displaced by the open-hearth process which produces a slag less rich in phosphoric acid. The practice has also been adopted of adding fluor-spar to the furnace in order to induce the formation of a more fusible slag, but thereby the solubility of the phosphoric acid of the slag in the weak citric acid generally used in testing its quality becomes impaired. The bulk of the basic slag now sold contains only about 10 % of phosphoric acid against 15 to 20 % in the older types of slag and the phosphoric acid is no longer soluble in weak acids. The new type of basic slag proves, however, little less effective, unit for unit of phosphoric acid, as a fertilizer, but freight charges, always a large item in the cost of basic slag to the farmer, now become doubled for the amount of phosphoric acid that is carried, apart from the increase in these

charges per ton. Attempts were in 1921 being made to replace basic slag by finely ground mineral phosphates as a fertilizer for grass land. American experience has always been favourable to these ground phosphates, and recent experiments in England have demonstrated that they effect in poor pastures the same encouragement of clover as is obtained from basic slag, even upon such unpromising land as the clays in the dry Essex climate. The phosphate rock from Nauru Island, that has passed from German hands into the control of the British Government, may prove of special value for application in this finely ground but otherwise untreated condition.

Plant Breeding.—Probably the plant breeders have during 1900–20 rendered the greatest services to agriculture, inasmuch as improvements in this direction—the introduction of new varieties giving large yields, better quality and more resistant to disease—are at once appreciated by the farmer and require no alterations in the methods of cultivation. It has been found possible to apply Mendelian principles with comparative simplicity and accuracy to the breeding of new varieties of plants, especially of cereals, and the results achieved have already experienced considerable commercial development in the case of wheat, barley, oats, maize, sugar-cane and cotton. The value of the Mendelian principle lies in the power it gives of combining in one of the selected descendants of a cross-bred individual unrelated valuable characters possessed by the parents separately.

In the case of wheat Biffen has shown that among the Mendelian characters that are transmitted as unchanged units are such quantitative properties as the resistance to disease, the normal percentage of nitrogen in the grain and the "strength" of the flour resulting from it, the stiffness of the straw, etc. One of the chief desiderata as regards English wheat has been an improvement in its strength, *i.e.* the capacity to yield a spongy elastic dough which will bake into a light loaf of large volume. This strength factor which is connected with the amount of gluten and therefore with the percentage of nitrogen in the flour is as a rule the property of spring wheats grown in a "steppe climate" with a short period of growth, with considerable rainfall in the early months exchanged for great heat and almost complete dryness before harvest. Wheats from Hungary, South Russia, Manitoba and the great plains of North America possess this quality, and Leclerc and Leavett have shown by sowing the same seed in different states how potent is the effect of environment and climate in determining the percentage of nitrogen and the strength of wheat. As a rule any of the strong wheats brought either from continental or American sources lose their strength completely when grown under English conditions. One wheat, however, of Galician origin but widely grown in America under the name of Red Fife, so widely indeed as to be the dominant constituent of such commercial grades as Manitoba and No. 1 Northern, does to a large measure retain its strength in England, the strength in this case being congenital and not the product of environment. Red Fife is, however, a poor cropper on most English soil, yielding but 3 qr. per ac. where the typical English wheats will yield four or five. Biffen has, however, employed it as a parent in the hope of combining the strength of the one parent with the cropping power of the other and one of the results of this cross, a wheat called Yeoman, issued to the public in 1915, is on its congenital soils—the warmer and better soils of the east and south-east of England—probably the heaviest cropper grown. Further, the quality of the grain is so high that the miller can use it without any mixture of strong foreign wheats, such as are necessary to the extent of 40% or more with ordinary English wheat. Another of Biffen's wheats, Little Joss, by its power of resisting rust, has proved a very heavy cropper and is now extensively grown on soils that remain fairly dry and warm throughout the winter. Saunders in Canada has effected a very considerable extension of the wheat area by the introduction of a wheat called "Marquis," another hybrid with Red Fife as one parent, which combines the good quality of Red Fife with a shorter period of growth and an earlier ripening habit, thus rendering wheat-growing safe in wide areas, as in parts of Alberta, where the crop was liable to ruin through the onset of early autumn frosts before harvest had been completed. On the average Marquis ripens six days earlier than Red Fife and thus in the Central Prairie region where frosts are expected between Aug. 27 and Sept. 2 Marquis can generally be grown safely though Red Fife is liable to be caught. In part the extension of Marquis may be put down to its superior cropping powers, but for one reason or another it has largely displaced all other spring wheats in the North-West. In 1918 the area under Marquis in Minnesota, the Dakotas, Montana, Manitoba, Saskatchewan and Alberta was estimated to amount to 20,000,000 ac. and the crop in Canada alone to 129,000,000 bus.—all the produce of what was but a single plant in 1903!

Immunity from Disease.—The inheritance of immunity from disease is best illustrated by the discovery of potatoes immune to wart disease.

About 1897 attention was drawn to the prevalence in certain parts of England and Wales of a disease of potatoes, generally found in old cottage gardens and allotments, which causes the potatoes to degenerate into a mass of dark corky excrescences and will in bad cases destroy the crop entirely. The disease is due to the attack of a lowly organised fungus, and the difficulty of dealing with it is due to the fact that once established in the soil the spores or some resting form of the fungus retain their life for an indefinite period of many years. Once the soil has become infected no practicable means has been found of cleaning it; even leaving the land down to grass for ten years has been found ineffective. Considerable areas in the industrial districts of Lancashire, Cheshire, Stafford and Shropshire, North and South Wales are subject to the disease and it became more widely distributed throughout the West of England as a result of the great shortage of seed potatoes in 1917, which caused men to plant anything that was available without inquiring into its origin.

The consequences would undoubtedly have been the complete destruction of potato-growing in those districts had it not been observed that one or two types of potatoes could be found growing unharmed in some of the old infected gardens. Further examination proved that these varieties were really immune to the disease, however heavily infected the soil, and though in themselves they possessed little commercial value they were at once employed as seed parents and have become the source of a new race of potatoes immune to wart diseases. Many of these are now proving to be good market varieties of heavy cropping power and by their aid potato-growing has been rendered possible in the infected areas which otherwise inevitably would have spread until the whole country would have been involved. As the disease has also obtained a foothold (its original habitat is unknown) in North America, Holland, Belgium and Germany, the value of this discovery of immunity is difficult to overestimate. From the study of this and other cases the conviction gains ground that the most fruitful method of dealing with plant disease will always be by the search for immunity rather than by methods of treatment.

Selection.—In the improvement of cereals considerable advantages have been derived by working on another principle than that of breeding, *i.e.* pure line selection. Very little improvement in a variety can be effected by what may be called "mass selection." If in going over a field of wheat a collection is made of the longest ears, or again if the heaviest grains are sorted out, no perceptible improvement is visible in the crop grown from the selection, not even if the process is repeated generation after generation. The superiority of the individuals selected has been due to some accident of nutrition and is not transmissible to the offspring. If, however, the selected individuals are sown separately, here and there among them will be found one which in the next and succeeding generations still preserves some superiority which is congenital to it and is maintained in succeeding generations even when the seed is worked up to a large crop.

An ordinary variety, say of wheat, really consists of an indefinite mixture of sub-varieties each of which, for many generations at least, breeds true in the case of cereals which are self-fertilized. Thus "pure lines" may be selected from single seeds of such self-fertilized plants and worked up to commercial stocks of seed. These pure lines may have some superiority, never, however, great, in cropping power over the mixed variety from which they are derived, and are also appreciably more uniform in such details as time of ripening and length of straw.

It has become evident that every commercial variety of cereals, even if of deliberately cross-bred origin, will be improved by pure line selections from time to time.

Nutrition.—It was still difficult in 1921 to discuss in any detail the progress that is being made in the study of animal nutrition, in regard to which the teachings of the scientific man have had much less effect upon the practice of the farmer than has been the case when the nutrition of the plant has been concerned.

The great shortage of cattle food during the war, notably in 1917 and 1918 when no tonnage could be spared for cattle food, did reveal two things, first, the dependence upon imported corn and oil seeds that British meat and milk production had fallen into, and secondly, the enormous waste that had been going on. It was estimated that the normal output of meat, milk and other animal products did not represent one-half, possibly not more than a third, of the amount that could have been obtained, not merely theoretically, but even in properly informed practice. At the same time certain lacunae in our theory were disclosed, which prevent the scientific man from setting out with any accuracy the limits within which the fattening of animals will proceed most economically. It will be seen that the problem is a very complex one. On the one hand, as regards the amount of food fed over and above the maintenance ration, the law of diminishing returns is found to hold for the amount of daily increase; on the other hand, the slower the rate of fattening, the

greater must be the non-productive consumption of food on maintenance only.

Again in the later stages of fattening the law of diminishing returns operates in another fashion, so that the increase of weight may be put on as offal fat of comparatively low value instead of as edible fat in the "meat" portions of the carcass. Much more exact information is therefore being sought as to the relations of the live weight increase to the progress in consumption of food and again to the changes in the composition of the carcass as the fattening process advances.

On the other side of the nutrition question recent work upon "vitamines" and accessory food factors is found to have its application to questions of animal nutrition. Not only the health and growth of certain animals, notably pigs, is in practice affected by the deficiency of the foods habitually used in these accessory factors, but again the fats arising from the animals, e.g. lard, bacon, even milk and butter fat, may in their turn become deficient as human foods because of the lack of the accessory substances in the food of the animal. Enough work has been done to show that in certain special cases of indoor feeding of animals not only the broad energy- and tissue-forming properties of the food have to be considered, but also the supply of certain accessories—energizers or detonators, whatever may prove to be their function. In practice the path of safety for all farm animals lies in a reasonably mixed diet, which includes some proportion of uncooked green food. Pigs and poultry have not infrequently been sufferers from diets insufficiently supplied with vitamines.

Animal Breeding.—Although in 1921 such progress had not yet been made with the very complex subject of animal breeding as to enable economic results to be obtained similar to those which had accrued in plant breeding, still the ground was being prepared by certain initial investigations for the mode of inheritance of some of the desiderated qualities in domestic animals, *e.g.* size, prolificacy, quality of wool, etc.

Punnett, for example, in England has thrown some light on the inheritance of size in fowls and rabbits, and again on the inheritance of fur, but by far the most important work in this direction has been done by Pearl in Pennsylvania. In studying the inheritance of milk yields he has first of all endeavoured to obtain a single figure characterizing the performance of a cow, a sort of index number. By a study of commercial milk records he has constructed a type curve showing the variation in milk yield for a cow during successive calvings, whereby if its milk yield in any one year is known this figure can be corrected to give the milk yield in the standard year used for comparison. A similar type curve can be constructed for the period of a lactation, whereby the yield for the whole period can be deduced from the yield ascertained during a particular month or less. Having thus obtained characteristic figures for cows, Pearl was in a position to compare the performances of cows with their offspring by different bulls. By tabulating all such comparisons obtainable with regard to a particular bull a characteristic mark is obtained for the bull. Some bulls are found always to bring about an increase in the milk production of the daughter over the dam; other bulls which had a great repute in their day and a fine record in the show yard equally invariably gave progeny yielding less milk than their dams. The value of this work in connexion with milk recording and breeding is evident; indeed in Denmark for some years the underlying principle has been appreciated in that prizes are offered for bulls, the award being based upon the milk tests of the bull's progeny. The difficulty attaching to the application of these results lies in the disinclination of farmers to retain bulls for service for more than two or three years; they are cast before there is any opportunity of testing the milk-producing quality of their offspring. (A. D. H.)

II. Administration and Legislation in the United Kingdom

As was inevitable, the World War gave rise in all countries to a great body of emergency enactments and temporary legislation affecting agriculture. Beyond these, however, the years 1917–21 saw a large volume of legislation which aimed at the reorganization of agriculture in Great Britain, and also inaugurated a definite agricultural policy, the main features of which found expression in the Corn Production Act of 1917 and the Agriculture Act of 1920. The principles underlying these Acts first were set out in the report of the commission appointed in 1915 under Lord Milner, and still more fully in the report of the sub-committee of the Reconstruction Committee under the chairmanship of Lord Selborne.

Briefly, these committees found that the position of the United Kingdom had, as demonstrated by the war, fallen into great insecurity in consequence of the neglect of agriculture which had been going on during the previous 40 years. In 1872 the arable land in the United Kingdom amounted to nearly 24,000,000 ac., and this had become by 1914 little more than 19,000,000 acres. The loss had been experienced chiefly in England and Wales, where the shrinkage had been nearly 4,000,000 ac., from 14,943,000 to 10,998,000 acres. This represents a great decline in the gross production of food, because it has been abundantly demonstrated that an acre of medium land under grass does produce only about one-third of the meat or milk that can be obtained from the same land if it is put under the plough and the crops are consumed by stock. Moreover, whenever there is a definite shortage of food the production of meat is in itself a wasteful process, from seven to ten pounds of real food being consumed by the animal in making one pound of food in the shape of meat or milk. The only gain in meat production is that the animal is able to convert coarse fodder like straw and waste materials like millers' offals into human food, but an animal like a pig, which is largely fed upon barley and maize meal, equally edible by human beings, becomes definitely wasteful of the resources of the country when a real food scarcity is declared. The comparison between the productiveness of grass and arable land may perhaps be illustrated most markedly by a consideration of the potato crop. An average yield of potatoes in England is about 6½ tons per ac., which represents over 2,000 lb. of dry food when all allowances have been made for waste. Under grass the same land would not produce more than 120–150 lb. of meat, *i.e.* about 100 lb. of dry food, or 160 gal. of milk, *i.e.* 170 lb. of dry food. Nor does the animal food, pound for pound of dry matter, possess more than a slight superiority over the potatoes in its power of maintaining human beings.

Before the War.—Roughly speaking, in the years immediately preceding the World War the United Kingdom was only producing about 42% of the food consumed by its people. The greater portion had to be imported, and this applied particularly to wheat of which only about one-fifth of the normal consumption was produced at home. This dependence of the nation upon external supplies of food was its great weakness revealed by the war. Not only was there the danger that the German submarine campaign might prove successful and force submission by starvation, but, even as it was, the country's effort was hampered by the necessity of allocating to food supply so large a proportion of the available tonnage needed for other purposes and of employing part of the naval strength to protect it. Again, the purchasing power and credit of the country were continually impaired by the enormous sums spent abroad for food.

The external food bill amounted to over £220,000,000 a year before the war, and during its latter stages this had risen to three times that sum. The enemy was not slow to realize that this was Britain's vulnerable spot. The attack failed, but the economic consequences pressed grievously upon Great Britain after the war. The recovery of Britain was deferred by the enormous purchases it must continue to make abroad in order to keep its people fed, and the sacrifices it must make in order to maintain the foreign exchange at a high level in order to meet these purchases.

It had often been argued that in case of emergency the grass lands of Britain constituted a great reserve of fertility which could be drawn upon for the growth of corn and other crops, but when the occasion came it was proved how little of this reserve was immediately available. Neither the men nor the horses, not even the buildings or the implements, required for arable farming, existed any longer. All the inertia of the farming community came into play against conversion, and despite the efforts of the State, armed with compulsory powers, proffering compensation against loss and assisting with fertilizers, seeds and machines, less than a further 2,000,000 ac. of grass land got broken up during the fateful years of 1917 and 1918. Once the art and means of arable farming have been lost, it is only slowly and at great expense that they can be improvised.

Concurrently with the decline in the production from British land in consequence of the conversion from arable into grass there had been a corresponding decrease in the agricultural population, which in England and Wales alone had fallen from

1,269,371 in 1871 to 951,674 in 1901, though by 1911 it had again risen somewhat, to 1,002,743.

This reduction of the agricultural community was not to be viewed with equanimity. A population dependent entirely upon manufactures gives rise to an unstable State, subject to violent fluctuations of prosperity because the causes that determine employment are apt to affect all industries simultaneously. Politically a country population is more sober and cautious, just as it is healthier and more reproductive and both physically and temperamentally better fitted for steady enduring work.

It was these two motives then that led to the legislation under review—the desire to ensure a greater production of food and the better cultivation of British land, and the desire to increase the rural population, neither of which could be attained if the old *laissez faire* policy were persisted in.

New British Policy.—What had been the origin of the dangerous situation in which the nation found itself in 1914? Taking extent of the arable land as an index, the high-water mark of English agriculture was reached in 1872. The later seventies were marked by bad seasons culminating in the disastrous experience of 1879. At the same time rapid progress was being made with the opening up of the American prairies for corn-growing and with the cheapening of ocean freights. This was a period of immense expansion in the new lands of the world; it saw the growth of the Middle West both in the United States and Canada, the agricultural settlement of the Argentine and other South American lands, the development of Australian wheat-growing areas and the commercial exploitation of southern Russia. As a consequence, prices of the great agricultural commodities, corn and meat, fell rapidly and continuously during the eighties and nineties. Wheat from an average of 54s. 8d. per qr. in 1871–5 fell to 22s. 10d. in 1894; the average return per acre on an arable farm for both corn and meat, estimated at 165s. in the first period, dropped to about 100s. between 1894 and 1900. As the rate of wages rose during the period and no great compensating factor was at work (other than the perfecting of the self-binder, which had made wheat-growing for export possible in the new countries), British farming was unable to adjust itself with sufficient rapidity to the vastly diminished returns. The great depression resulted in the ruin of a large proportion of the old farmers, in a wholesale loss of capital, and, worst of all, in an entire loss of confidence in an industry that had ceased to control the prices of its main products. The industry met the situation by a drastic reduction of expenditure and the conversion of arable land into grass on which the labour bill was small. The process was aided by the continued development of the milk trade. From 1900 onwards the course of prices turned upwards—the world's population was growing up to the food supply, and the new farming adjusted to the changed conditions began to become steadily prosperous. But the memory of the great depression remained, confidence was small and capital mistrustful. Men hesitated to adventure their money in a business which was liable to a break of prices such as had occurred within all too recent a date. Such were the conditions that had led to the dependence of the nation upon foreign food and particularly upon foreign corn; hence the object of the policy was to give the arable-land farmer security that he should not in future be subjected to a devastating break in prices such as had occurred in the eighties and nineties of the last century. With this security in the background it was thought the current conditions would be favourable enough to bring about an extension of the arable area.

As the Prime Minister said in his famous speech to agriculturists in Oct. 1919:—

"The Agricultural industry is the greatest industry in the State. It ought therefore to be a primary concern of every Government and of every Statesman to do what in them lies to promote that industry. I regret to say that in no civilized country has the State done so little during the last generation to foster agriculture. I hope that record will now be rolled up and that there will begin a new era in the relations of the State with the greatest and the most important of its industries . . . The question is 'Are we going back to the dismal pre-war conditions or are we merely going to maintain the progress which has been made?' Are we not going further? There can be but one answer from every man who loves his country. We must go forward. How is it to be done? You must have a settled policy with regard to agriculture. The first condition is security to the cultivator: security in the first place against ruin through the violent fluctuations of foreign agriculture."

Acts of 1917, 1919, 1920.—The method by which this security was given in the "Corn Production Act" of 1917 and the "Agriculture Act" of 1919 embodies a novel principle. Instead of a protective duty, which enhances the price to the consumer, a bounty was given to the producer if the average market price of wheat or oats fell below certain guaranteed figures. In the Corn Production Act certain guaranteed prices were set down for six years ahead, but at that time it was vain to make forecasts of the trend of prices, and actually none of the guarantees then given ever came into operation. By the Agriculture Act of 1920 basal prices of 68s. for wheat and 46s. for oats were taken for the year 1919, and commissioners were appointed who were charged to determine from year to year how far the average costs of production of wheat and oats had changed in that year from those of the basal year 1919, whereupon the guaranteed figure of 68s. or 46s. was varied in like proportion. If for example the commissioners found that in 1923 the cost of production of a quarter of wheat was on the average 20% less than in 1919, the price guaranteed by the Act would become 54s. 5d. Should then the average price actually obtained by farmers, as ascertained by the official corn market returns from Sept. 1 to March 31, amount to 52s. 11d. and thus leave a difference of 1s. 6d. per quarter between the guaranteed and realized price, the Government would be liable to pay 1s. 6d. per quarter on all the wheat produced. But since the verification of the actual quantities grown presents great administrative difficulties the crop is assumed to be 4 qr. to the acre, and the undertaking of the Act was to pay four times the difference between the average realized price and the guarantee on every acre of wheat grown, five times the difference in the case of oats, on the assumption of an average crop of 5 qr. to the acre. It will be seen that the payments made to any individual were independent of the actual price he happened to obtain for his particular sample. The normal course of trade is not interfered with and the grower gets the benefit of any superiority of quality or favourable market conditions he may possess.

The guarantees were confined to wheat and oats, not so much to increase the specific production of those cereals as to encourage arable farming, since one or both of these crops formed an inevitable part of every rotation in the United Kingdom.

Inevitably the State was involved in a considerable liability in any year in which a break in prices might occur after harvest but in which the costs of production had not been affected. These are, however, precisely the occasions dreaded by the farmer mindful of the past, and the Act was designed to give the farmer such assistance as might save him from ruin, though it would not provide a profit. The State, however, only accepted this liability in order to bring about an increase of production; it recognized an obligation towards agriculturists, but on the other hand it required that the land should be put to proper use. In the Corn Production Act the Board of Agriculture was given power to enforce proper cultivation where the rules of good husbandry were being neglected and also to dictate the mode of cultivation or the use to which the land should be put for the purpose of increasing the production of food in the national interest. In case of failure to comply with the directions the Board could cause the owner to terminate the tenancy, or, if the occupier were the owner, could enter itself and cultivate.

These somewhat drastic provisions, which were exercised under the Defence of the Realm Act during the war, were strongly opposed by both owners and occupiers and became greatly modified when the Agriculture Act of 1920 replaced the Corn Production Act. Practically under the new Act the powers of the Ministry of Agriculture were limited to the enforcement of cultivation according to the rules of good husbandry.

Where an estate is grossly mismanaged to such an extent as to prejudice materially the production of food thereon or the welfare of persons engaged in the cultivation of the estate, the minister may, after holding a public inquiry, appoint some person to act as receiver and manager of the whole or a portion of the estate, an appeal being allowed to the High Court. The Ministry's powers were delegated to cultivation sub-committees of the agricultural committees of the county councils which had been set up by the Ministry of Agriculture Act of 1919.

There was, however, another public interest to be considered—

the condition of the labourers engaged upon the land. In order to give them security the Corn Production Act, whose provisions were renewed in the Agriculture Act, provided for the setting up of an agricultural wages board, empowered to fix minimum rates of wage for persons engaged in agricultural work, no such rate to be less than 25s. a week for able-bodied men. The wages board consisted of an equal number of representatives of employers and workmen, together with certain appointed members nominated by the Board (Ministry) of Agriculture. District wages committees were set up for administration of the Act within their areas, and these committees proposed local rates of wage and incidental regulations regarding their area for the confirmation of the central wages board. As the setting up of the wages board coincided with a time of rapidly advancing wages in all industries the minimum rates of wage were repeatedly advanced under its orders. In June 1921 the lowest rate amounted to 43s. 6d. per week of 52 hours in summer and 48 in winter, and this rate prevailed in the English counties where the average rate of wages before the war was not more than 15s. An incidental result of the wage regulation was the practical abolition of all allowances which in many parts of the country were made to labourers in lieu of cash, *e.g.* milk, potatoes, bacon, coal, etc. A deduction may still be made for cottages but the amount of deduction allowable is fixed by the wages board and may not exceed 3s. a week. It may be noted that with one or two comparatively small exceptions the minimum wage regulations succeeded in avoiding strikes in the agricultural industry during a period in which labour conditions were very disturbed.

The Corn Production Act, and in its turn the Agriculture Act, thus represent a definite attempt on the part of the State to frame a constructive policy for agriculture in the national interest. The two main interests concerned, the farmers and the labourers, were given some security of a return for their work, the State obtained increased production and some control over the use of the land. Should it prove, however, that even with guaranteed prices the occupiers of land were not responding by an increase of production to any payments made by the State under the guarantees, the purpose of the Act would be unfulfilled. To meet this the Act gave the Ministry power by Order in Council to give four years' notice of the determination of its powers under Part I. of the Act, which dealt with the system of guarantees, the control of cultivation and the regulation of wages.

It should be noted that the Agriculture Act contemplated the delegation of the powers of the Ministry to control cultivation to committees of the county agricultural committees which were set up by the Ministry of Agriculture Act of 1919. This was a continuation of the procedure adopted during the war, when the Board of Agriculture appointed county executive committees in order to carry out the orders under the Defence of the Realm Act for the increase of food production.

The second part of the Agriculture Act of 1920 also contained a series of provisions amending considerably the Agricultural Holdings Acts. The main feature of this legislation entitles a tenant who is given notice to quit to compensation for disturbance. This compensation amounts to one year's rent, or, if greater, to the proved loss and expenses incurred in quitting the holding, up to a maximum of two years' rent. Compensation is not payable to a tenant who was not cultivating his holding according to the rules of good husbandry, or who had failed to comply with an order to pay arrears of rent or to repair a breach of covenant. The landlord may also demand that the question of the rent payable for the holding shall be submitted to arbitration and if the tenant refuses to agree to this demand may then give him notice to quit without compensation for disturbance. The Agriculture Act applied to Great Britain only, and the procedure of the Corn Production Act in setting up an agricultural wages board for England and Wales was somewhat modified as regards Scotland and Ireland.

In 1919 the Ministry of Agriculture and Fisheries Act was passed, which, besides changing the title of the Board of Agriculture, set up a council of agriculture for England and Wales, partly elective and partly representative, which should meet at least twice a year for the purpose of discussing matters of public interest relating to agriculture and of making representations to the minister. From these councils are selected the members of the Agricultural Advisory Committee, which has the duty of advising the Ministry on all matters (except as regards fishing) relating to the exercise of the powers of the Ministry. These two bodies resemble in many respects the Council and Board of Agriculture in Ireland, though neither of them possesses that control over expenditure which the Board of Agriculture in Ireland can exercise over the expenditure of the endowment fund enjoyed by the Department of Agriculture in Ireland. The Act also provides for the setting up by the county council in each county and in certain county boroughs of an agricultural committee. These committees must set up sub-committees to deal with small holdings and allotments, with the powers to regulate cultivation delegated to them by the Ministry under the Corn Production and Agriculture Acts, and with drainage under the Land Drainage Act of 1918. This committee may also, by the direction of the county council and with the concurrence of the Board of Education, take over from the Education Committee the control of agricultural education.

Land drainage for generations had been the subject of legislation, but it was evident that existing powers were inadequate to provide for the efficient management of the drainage of the majority of the river basins of England and Wales. In many areas there was a multiplication of authorities, many of whom possessed insufficient rating powers to be able to carry out works falling within their area but vital to the whole river basin. In other cases the area was inadequate or the existing commissioners of sewers failed to execute their duties. The Drainage Acts of 1914 and 1918 gave the Ministry of Agriculture powers to make orders constituting drainage districts, altering the boundaries of existing drainage areas or enlarging their powers of levying rates or borrowing. The Ministry may also act itself in default of any drainage authority or may delegate its powers to a committee of the county council or councils of the area concerned, though its power of executing any such work of drainage and of recovering from the owners affected is limited to schemes costing not more than £5,000. By means of these Acts and of the Defence of the Realm Act powers possessed by the county executive committees, much valuable work had been accomplished by 1921 in cleaning out the smaller watercourses and improving the drainage of many minor areas subject to flood or unfertile because of waterlogging. Larger schemes exist for dealing comprehensively with important areas like the Ouse basin, which embraces some of the most valuable land in the Fens, but these schemes are likely to remain in abeyance while the difficulties of financial stringency and high cost of labour prevail.

One of the heaviest tasks which was assigned to the Board of Agriculture at the close of the war was the settlement upon the land of such ex-service men as desired holdings and could show their suitability to occupy land. Under the Small Holdings and Allotments Act of 1908 county councils had been empowered to purchase land and equip it for small holdings, but it was necessary that the schemes they framed for this purpose should show a reasonable prospect of being self-supporting on the rents that could be expected. It was evident, however, at the close of 1918 that little settlement of ex-service men could be effected upon such terms. Not only had the price of land, especially of land suitable to small holders, increased very largely, but the cost of buildings, equipment and adaptation, necessary in the majority of cases before a small holder can be placed upon the land, had grown to three or four times its pre-war magnitude. No such rents could be charged as would make the small holdings pay, nor could county councils be expected to burden their rates with the losses that would accrue if the holdings were let at reasonable rents. Accordingly, by the Land Settlement Act of 1919, the State accepted this liability and allotted a sum of £20,000,000 for the provision of holdings for ex-service men. The Act retained the county councils as the agencies for the provision of small holdings, and strengthened their powers to acquire land compulsorily for the purpose by purchase or by hiring. In the main the £20,000,000 mentioned above has been lent to the county councils in order to enable them to acquire land and adapt it for letting as small holdings.

The county councils could not take up such loans, did not the Act further empower the Ministry for seven years after the passing of the Act to pay to the county councils any losses they had incurred in the provision of holdings under approved schemes. The loss each year consists of the excess of the loan charges over receipts for rent together with administrative expenses. Then on April 1 1926 a valuation is to be made of all the land acquired by county councils under the Small Holdings Act, and this valuation will be compared with the liabilities incurred by the council. The Ministry will then assume the responsibility of paying such portion of the loan charges due from the council as represented the excess of liabilities over the valuation. Finally the councils will be left as owners of the small holdings that have been set up, with only such charges to meet as might reasonably be expected to be covered by the rents in the then conditions of the land market.

By the end of May 1921 some 34,000 applications for holdings had been received in England and Wales alone, 29,000 of which had been approved by the county councils; 277,000 ac. of land had been acquired, and 15,000 men had already been placed upon it. Slow as this progress may at first sight appear it has to be remembered that land cannot be acquired at short notice nor sitting tenants displaced except at the cost of burdening the scheme with impossible charges for compensation. The work of building and adaptation had also had to be carried out under the most difficult and burdensome conditions, at a time when both labour and materials of all kinds were abnormally deficient. In the great majority of cases the holding created was inevitably uneconomic, in the sense that the capital outlay on land, buildings and roads, fencing and other incidentals, cannot be repaid by the rents which can be paid under anything like existing conditions. The total cost of the scheme to the State, *i.e.* the expenditure that would have to be written off as not represented by the market value of the resulting holdings, can only be estimated, but seemed likely to amount to about £8,000,000. Undoubtedly the State accepted a very heavy financial responsibility in this scheme of land settlement for ex-service men, but it had to be taken as a partial repayment of the debt due from the State to the men who fought for it. As part of the national policy they were promised access to the land, and the conditions prevailing at the close of the war made it impossible to redeem that promise except at a loss.

Education and Research.—From the administrative point of view the chief advance effected during 1900–20 was the organization throughout the United Kingdom of a scheme of agricultural education and research. State assistance to agricultural education may be said to have begun with the Technical Instruction Act of 1889, but organized research remained practically unprovided for until the setting up of the Development Commission in 1908. The scheme then adopted was furthered by the allocation of fresh funds for the purpose after the end of the war, and most of the institutions contemplated were at work in 1921. The essential feature of the scheme is the provision of institutes, each dealing with a particular aspect of the subject and as a rule associated with a university possessing an agricultural department. The State exercises no direct control over the nature of the investigations conducted, other than the sanction accompanying its annual contribution, which is in the nature of a grant in aid. General policy is also reviewed at the meetings of a research council composed of the directors of the institutes and officials of the Government departments concerned. The staff of the research institutes are not civil servants but are engaged by the respective governing bodies; the State does, however, provide for a stated scale of salaries with increments and superannuation allowances. The annual expenditure on the scheme amounted to £140,000 for England and Wales for the year 1921–2, and to £5,400 for Scotland for the same period, but the Irish expenditure cannot so easily be differentiated from the other commitments of the Department of Agriculture.

The Experimental Station at Rothamsted, the oldest in the world, has been greatly enlarged and developed as the Institute of Research in problems of soil and plant nutrition, to which has recently been added a second institute dealing with plant pathology, embracing entomology, mycology and helminthology. At Cambridge is situated the main institute for research in animal nutrition, and a second station also exists in connexion with the university of Aberdeen. At Cambridge, also, investigations have been made dealing with animal-breeding from the genetic side and with problems of reproduction, and the plan was to draw all these threads together so as to make at Cambridge an institute dealing broadly with animal husbandry in all its aspects.

Research in dairying problems is provided for by an institute in connexion with the University College at Reading; and a second station was projected in 1921 in connexion with the Agricultural College at Glasgow. The plant-breeding station and institute proper are situated at Cambridge; a second station, specializing mainly on grasses, clovers and fodder crops appropriate to the moister climates of the west, is associated with the University College at Aberystwyth; and a third station was planned in 1921 in Scotland. The commercial development of the products of the plant-breeders is provided for by the National Institute of Agricultural Botany, which has also recently been set up at Cambridge largely by contributions from trade sources.

Research in fruit-growing problems is dealt with by an institute associated with the university of Bristol (Long Ashton) and a second station situated at East Malling in Kent, further sub-stations being in contemplation at Cambridge for the eastern counties fruit district and elsewhere. The Bristol centre also deals with cider-making and with the various processes of fruit preservation, to which end a small commercial factory is maintained at Chiming Camden.

The Imperial College of Science in London maintains an institute for work in problems of plant physiology, utilizing for its experimental cultures various institutions near London, such as Rothamsted, the Lea Valley Experimental Station which deals with glass-house problems, the East Malling Fruit Station, and the Experimental Gardens of the Royal Horticultural Society at Wisley. Mention should also be made of the John Innes Horticultural Institute at Merton, which under Mr. W. Bateson deals mainly with genetic problems, though this institution derives its income entirely from trust funds.

Schemes for dealing with research on problems of agricultural machinery and again with veterinary science were under consideration in 1921. As regards the latter subject the only institution mainly concerned with research is the laboratory maintained by the Ministry of Agriculture.

The complete scheme also provided an annual sum for grants in aid of particular investigations set on foot by individuals who might not be attached to a research institute, and again for postgraduate scholarships in order to ensure a supply of properly trained workers.

Higher instruction in agriculture is provided for by agricultural colleges, which as a rule are attached to one of the local universities and have a distinct regional responsibility as to the provision of information and technical advice to farmers occupying land in the area allocated to the college.

In Scotland three such colleges are attached to the universities of Aberdeen, Edinburgh and Glasgow; in England, there are departments of agriculture attached to the universities of Durham (Newcastle), Leeds, Cambridge, Reading (Oxford), and in addition four residential agricultural colleges—the Harper Adams College at Newport, Salop; the South-Eastern Agricultural College at Wye, Kent; the Midland College at Sutton Bonington and the Seale Hayne College at Newton Abbot, Devon. In Wales the University Colleges of Bangor and Aberystwyth maintain similar agricultural departments. In Ireland higher instruction in agriculture is given at the Royal College of Science in Dublin and the Albert Agricultural College at Glasnevin, while there are professors of agriculture at the Queen's Universities of Cork and Belfast.

Intermediate education in agriculture is in Scotland organized by the agricultural colleges through extension lecturers attached to the various counties. In England and Wales the county councils are the responsible authorities, and the Ministry of Agriculture provides an agricultural organizer for each county and gives assistance towards the setting up of a farm institute, intended to give instruction by means of short courses for the sons of farmers, etc., who cannot leave the farm for the long periods demanded by the agricultural colleges. In Ireland intermediate instruction in agriculture is given at the Munster Institute, Cork, the Ulster Dairy School and the four regional agricultural stations at Athenry, Ballyhaise, Clonakilty and Strabane.

Steady progress has been made in all parts of the United Kingdom in the schemes for the improvement of live stock, by the dissemination among the smaller farmers of improved sires. In Ireland, where the scheme came into operation in 1911, premiums, to which both the Department and the local authorities contribute, are given towards the purchase of approved bulls and other sires, and the success of the scheme is manifest in the improvement effected in the quality of the store cattle exported for fattening to Great Britain. In England and Wales farmers are encouraged to form societies for the purchase of a bull or the hire of a stallion, and a grant is made towards the cost of the sire, which in the case of a bull may not exceed £20 or one-third of its cost. The work of forming societies for recording the milk yield of the cows of the members has been vigorously prosecuted, and the growth of the movement is shown by the fact that 637 cows obtained certificates in 1915 and 16,211 in 1921. The high prices obtained for recorded cows and their progeny show the value that farmers attach to milk records.

III. The War Period

For a long time after the declaration of war no special effort was made in the United Kingdom to develop agriculture and increase production of food. A measure to prevent the slaughtering of calves and pregnant animals was passed in 1914, but no other legislative action was taken until the close of 1916. Proposals which had been made, such as those of the Milner Committee, to guarantee a price for wheat or to give other bounties on production, were turned down on the broad principle that any interference with the free play of the market would impair the confidence of the trader and reduce importation to a greater degree than the increase in production. In 1915 in response to the general feeling farmers had increased their acreage of wheat by 430,000 ac. and of oats by 200,000, but this increase had chiefly been attained at the expense of the barley crop, for there had been no increase in the total extent of land under the plough. In 1916, however, the wheat area went back by 280,000 ac., and a low yield per acre was obtained. The potato crop also was much below average. It may be noted here that, speaking generally, except in the magnificent harvest of 1914, the seasons during the World War were very adverse to arable cultivation, being characterized by wet seeding-times and harvests, with spring droughts. It was not until 1917–8 that there was a favourable autumn and spring for sowing, but that promise was belied by a disastrous harvest-time for all the western and northern parts of the kingdom, with rains so heavy and protracted that no inconsiderable proportion of the corn crops were never harvested.

Intensified Production.—It was not until the close of 1916 that any action was taken to stimulate production. By that time the effects of the enemy interference with the free play of the market and the indifferent output began to be apparent in rapidly rising prices for all the prime food products—corn, potatoes, meat and milk. At the same time the withdrawal of labour from agriculture was bringing about a still further diminution in the area under wheat, of which at the close of 1916 it was estimated that 15% less had been sown than at the corresponding season in the preceding year. The appointment of a Royal Commission on

Wheat Supplies, which [illegible] the purchase of wheat and the operations of the milling trade, was followed by the appointment of a Food Controller and a promise in Dec. of certain guaranteed prices for wheat, oats and potatoes. At this time Rowland Prothero (afterwards Lord Ernle) had become President of the Board of Agriculture, and he proceeded to set up a Food Production Department which would take charge of a national effort to obtain more food from the land. To this department came as chief Sir Arthur Lee (afterwards Lord Lee of Fareham).

The policy adopted aimed at obtaining an increased acreage of arable land and as large a proportion of wheat and other bread corn as possible. Success depended upon the coöperation of the farmers, upon securing additional labour and upon assisting the farmer to obtain supplies of all kinds—horses, tractors, seeds and manures.

The first step was to set up War Agricultural Committees in each of the counties of England, Wales and Scotland; in Ireland the existing statutory County Council Committees on Agriculture were available for the same purpose. In England smaller executive committees were afterwards appointed, to whom were entrusted in the main the special powers which had been conferred by D.O.R.A. on the Board of Agriculture. District committees, and even in some cases parish committees, were further appointed. The staffs required for the executive committees were made up from the county council staffs and officers of the Land Valuation Department and Inland Revenue, while district commissioners appointed by the central department for small groups of two or more counties served to bind the whole organization.

As it was already Jan. 1917 before the Food Production Department was set up, it was impossible to effect much increase in the crops of that year, and in practically all cases it was obtained by voluntary response to the appeal for greater production. In England and Wales a further 286,000 ac. were put under the plough; the increase in wheat was 50,000 ac., in oats 616,000 ac. and in potatoes 220,000 acres. Scotland, having suffered less loss of arable land in the generation prior to the war, had smaller opportunities for reconversion from grass into arable, but added some 50,000 ac. to the plough land. In Ireland, however, the greatest extension was possible because of the much smaller draft that had been made on its man-power. An Order in Council was made requiring all Irish occupiers of more than 10 ac. to add 10% to their area under tillage, except in cases where the arable already amounted to 50% of the total cultivable area of the farm, and this resulted in an addition of nearly 650,000 ac. to the plough land of that country.

While this was going on during the spring of 1917 the county executive committees with the help of their district committees carried out a survey from farm to farm which revealed in all too many cases into what a state of neglect the land had been allowed to fall. Notices were served calling for improved cultivation, and in the worst cases the tenancies were determined, the executive committees either approving a new tenant, or taking the land under their own control. The central department framed a programme for 1918 which provided for the ploughing-up in England and Wales of 2,000,000 ac. of permanent grass as compared with 1916, and in Scotland of 350,000 acres. A quota was fixed for each county, based upon such considerations as the area which had been converted from arable into grass land since 1872, the existing proportion of arable in the county, the labour still upon the land, etc. Each county in its turn divided its quota among districts and eventually among the parishes and the individual farms, orders to plough certain fields being served upon the occupiers. These "ploughing orders" in many cases excited violent opposition, and sustained attacks were made upon the Department on the specious plea that ignorant officials were ordering grass land, which was providing meat and milk, to be converted into plough land which would yield nothing. Time considerations alone permitted of no appeal from the order of the committees, who had perhaps acted in some cases on the principle of making every man do a share proportional to his acreage without consideration of the character of the holding. But the mistakes made, if one is to judge by the mass of the results afterwards realized upon the broken-up land, affected but a small proportion of the land ordered to be put under the plough. The opposition both of occupiers and owners to the plough policy must be set down to the grass-land tradition, which the great depression of 1880–1900 had so firmly impressed on English agriculture.

None the less the programme was adhered to, and, aided by favourable weather in the winter and spring of 1917–8, a remarkable increase in the cultivated area was achieved. The disturbed state of Ireland prevented the realization of the plans which had been formed for a still further increase of 5% in the cultivated area. The tables show what was actually obtained in each of the three countries.

Arable land	19,320,823	19,405,076	19,652,676	21,122,750
Wheat	1,904,932	2,051,729	2,103,498	2,793,049
Barley	1,871,169	1,651,878	1,796,066	1,838,356
Oats	3,877,964	4,146,856	4,763,989	5,603,423
Potatoes	1,197,008	1,144,375	1,364,967	1,505,176
All crops other than temporary grasses and fallow	12,410,268	12,254,450	13,295,707	15,228,566

Speaking roughly, about 40% more grain was produced in 1918 than in 1916, and if the potato crop is also taken into account the 1918 crops represent a saving in tonnage (and shipping was the limiting factor in the prosecution of the war at that time) of 2,600,000 tons. Results would have been even better had it not been for the disastrous harvest weather, which caused the total loss of something like 5% of the grain crop, and rendered even more unfit for any other purpose than cattle-feeding. The occurrence of so continuous a succession of heavy rains was naturally regarded by the opponents of "ploughing up" as a justification of their adhesion to grass. It did indeed put an end to the plans which had been made for a further extension of the arable area in 1919. Work on most farms had fallen badly into arrears, and land had become foul and weedy, so that it seemed preferable to concentrate the available labour on the existing

tillage land rather than to attempt to increase its area in the face of the general opposition of the agricultural community.

Labour Supply.—Turning now to the means by which this increased production was realized in war-time, the prime difficulty experienced was the lack of labour. Grass land had often been described as a reserve of fertility that in case of need could be converted into crops, but this view had ignored the facts that laying down to grass is accompanied by the permanent loss of men and horses, implements and even buildings. When the need comes tillage cannot be resumed at pleasure; the men and machinery are no longer there. In Jan. 1917, when the food production campaign began, the 800,000 men employed in agriculture in 1914 had fallen to 562,000, and as about 180,000 of these were of military age and fresh drafts were urgently needed for the army, some new sources of labour had to be tapped. The operations of voluntary recruiting, and the action of local tribunals in granting exemptions, had produced very unequal results; the eastern and home counties, for example, had parted with a much larger proportion of their men to the colours. For a time in 1917 the calling-up of men from farms was suspended, but the spring offensive of 1918 resulted in a fresh call for 30,000 Grade 1 men from agriculture, 22,600 being actually called up. Meantime, however, the War Office rendered great assistance by the release of men on home service for short periods when the call for labour was greatest. In the spring of 1917, 21,000 ploughmen were lent for two months, together with about an equal number of other men with some experience of the land or of horses, and these men did much to render possible the first increase of tillage land. Though 18,000 of these men in Category A had to be returned to the army in May 1917, almost an equal number of men on home service were released for the harvest of that year. Other men were furnished by the military authorities during the autumn and winter, until in the spring of 1918 there were about 62,000 men working upon the land though nominally engaged on military service.

Assistance was also obtained from enemy prisoners-of-war. Early in 1918 prisoners at work in France, who were skilled ploughmen and had other agricultural experience, were brought across and established in camps of from 25 to 40 for work upon farms throughout England. The first prejudice against the employment of these men was soon dissipated as their skill and willingness to work became apparent, and eventually a certain number were even allowed to be housed upon farms without guards. As a rule these men were employed upon the Department's ploughing contracts or drainage operations, or other work that would absorb a gang of men and minimize the number of guards required. In the great majority of cases the German prisoners did excellent work and even came to be preferred by farmers to the local labour that had been left to them. Nor did any trouble arise over discipline; the tale is told of the guard who was brought back to camp helplessly drunk, supported by two of his prisoners, with a third carrying his rifle.

Various attempts were made to recruit civilian labour permanently and for special harvesting operations, but with little success. The only valuable recruits that were obtained were the public-school boys, some 4,500 to 5,000 of whom were formed into camps for the harvest and did service that was much appreciated, and again the camps of Boy Scouts, who in their turn did first-rate work for the farmers with whom their camp was placed. A certain number of "conscientious objectors" were told off for agricultural work, but the feeling against them in most rural districts was too strong to permit of their employment, and such of them as were engaged in camps proved of little use.

The greatest part of the accessory labour required in order to carry out the agricultural programme of 1917 and 1918, was provided by women. The supply was organized by the Women's War Agricultural Committee in the counties and by the Women's Branch of the Food Production Department. In the first place the employment for part or whole time of the women resident in the villages, who, in England at any rate, had largely ceased to work on the land, was revived, with the result that over a quarter of a million were at work in 1918 as compared with less than 100,000 before the war. Some assistance was given to these workers by the supply of boots and other outfit for farm work. Considerable camps were also formed of college students for temporary labour in the harvests of 1917 and 1918, and these women did excellent service in flax-pulling and other seasonal operations. But the chief effort was to provide a mobile force of women's labour from sources that did not usually furnish land workers, and at the beginning of 1917 the Women's Land Army was organized. The recruits were very carefully examined for fitness; indeed, something like 75% of the first 47,000 who volunteered were rejected, though by 1918 a considerable improvement in the material coming forward became manifest. Most of the women had to be trained, even if only for a few weeks, and in addition to the facilities provided by certain agricultural colleges and farm schools, over 600 special training centres were established. A minimum wage was laid down, at first 18s. and later 20s. a week, and in addition an outfit of the necessary clothes was provided. Depots had also to be established where the women who were waiting for employment or temporarily unengaged could be housed, and the women were eventually distributed between farm work, the Forage Department of the War Office and the Timber Supply Department.

At first considerable prejudice had to be overcome on the part of farmers, and again great difficulties were experienced in assuring proper accommodation for the women on the farms, but by the winter of 1917–8 some 7,000 were at work, and the number increased to 16,000 in the harvest of 1918, until the workmanlike costume of the landswomen, with their breeches and smock, became a familiar feature of all country life in England and Wales. On the whole these women proved of most service as milkers and in charge of stock and horses, for which many of them showed a special aptitude. Others again developed into very efficient drivers of motor tractors.

After the war and the return of the agricultural labourers on service, the demand for whole-time women's labour to a large extent disappeared. Moreover, a large proportion of the landswomen, especially the educated women, had taken on this kind of work for patriotic reasons, and had no call to the life of an agricultural labourer, so that the Women's Land Army was disbanded in 1919 and very few of the workers so recruited remained in 1921 upon the land. Undoubtedly, however, a certain number of women whose circumstances permitted were led to take up farming as a profession, and the whole movement, over and above the indispensable work it actually accomplished at a critical time, led to the diffusion through the community of a much better understanding of agriculture and rural life.

Tractors.—After labour, the provision of implements and especially of tractors proved the main difficulty of the Food Production Department. At the outset, in the early spring of 1917, with the immense urgency of getting land ploughed forthwith for the harvest of that year, it was necessary to buy every and any tractor available. Something under 500 were at work in three months, together with about an equal number of privately owned tractors which were controlled by the Department in order to get a maximum of work out of them. The Department engaged the ploughmen and operated the tractors, a charge being made to the farmers of 15s. to 20s. per acre for ploughing and half that rate for cultivating. Naturally the service did not pay its way; many of the tractors were far from efficient, and with the limited training that had been possible the drivers were at first unable to get a good average acreage worked per day. As experience of the various types of tractors accumulated it was decided to concentrate the main effort on the production of the Ford tractor, the specifications of which were placed by Henry Ford at the disposal of the Government. It was found possible neither to manufacture any of the British types nor to undertake the production of the Ford tractor in England, so entirely had British engineering works been turned over to the output of war material. Instead, orders were placed with Mr. Ford, and delivery began early in 1918. By the end of the year the Department was operating 4,200 tractors, despite the withdrawal of the large numbers of earlier types, and a further 3,000

had been sold to farmers from the supplies ordered by the Department. In the year 1918 650,000 ac. were ploughed and 580,000 ac. were cultivated by the Department's tractors; and in many districts where the means for arable farming had run low the ploughing programme could have been carried out in no other way. Nor was it the ploughing only that was forwarded; the difficult harvest of 1918 was in many cases only won through the capacity of the tractor to get the binders over a large acreage in a short time. Great as were the expenses attending the tractor programme, it was justified not only by the immediate results but by the education it afforded the British farmer in the use and value of mechanical traction, an education which might have required a generation under peace conditions.

In addition to tractors, the Department obtained sanction for the purchase of 30,000 horses, and formed gangs of teams to work under the district committees in parts of the county where the programme of ploughing-up grass land was beyond the strength of the farmers themselves. The numbers purchased were limited by the skilled ploughmen available to go with them, but something like 10,000 horses were working under the orders of the Department at the end of 1918, and an equal number had been lent to farmers. The steam-ploughing tackle existing in the country was also organized, and the owners engaged to keep their machines at work not only through the winter but also overtime and on Sundays. Facilities were given for the manufacture of further sets of tackle, until there were 90 more at work by the autumn of 1918. A very great share in the programme of extra cultivation was accomplished by the energy of the steam-tackle owners. Indeed, between their first meeting in March 1917 and the end of that year over 1,000,000 ac. of ploughing and cultivation had been accomplished, and 23,000 ac. had been mole-drained. The Department also purchased in America, and loaned or sold to farmers, large numbers of other implements, the manufacture of which in Great Britain had been to a large extent suspended in favour of munitions. Something like 5,000 binders, as many harrows and proportional numbers of other implements, including nearly 500 threshing-machines, were thus obtained by the Department and disposed of to farmers.

Fertilizers.—The effect of two and a half years of war and the increasing shortage of tonnage had begun to be manifest early in 1917 in a very marked disorganization of all the sources of supplies needed by the farmers—fertilizers, feeding-stuffs, seeds and minor but still essential articles like sulphate of copper and binder twine. The Food Production Department took charge, and achieved remarkable success in both extending supplies and regulating distribution to ensure equality of treatment and the saving of transport. In nearly all cases the organization was carried out through the trade concerned, the members of which formed associations and agreed to pool their resources and limit prices. Practically the only nitrogenous fertilizer available was sulphate of ammonia; shipping was no longer available from Chile for nitrate of soda, of which an earlier large Government purchase could not be moved and had eventually to be resold. Prior to the war the production of sulphate of ammonia in the United Kingdom had exceeded 400,000 tons per annum, of which about 70% was exported, while the home consumption for agriculture did not reach 70,000 tons, and indeed was not more than 78,000 tons in 1916. The propaganda and distribution scheme of the Food Production Department secured the use of as much as 234,000 tons in the year June 1917–June 1918. Basic slag was similarly dealt with, grinding facilities were obtained, and the consumption was increased by something like 200,000 tons. Owing to the shortage of shipping it was impossible to maintain supplies of phosphate rock for the manufacture of superphosphate, but some alleviation of the scarcity was obtained by the diversion of shipping to North Africa, and over 750,000 tons of superphosphate were distributed for the year ending June 1918.

Thus the work of the Food Production Department did succeed in putting at the disposal of farmers in the harvest of 1918 a substantially greater amount of fertilizers than they had been in the habit of consuming prior to the war, and this at a time when the sources were diminishing had no governmental stimulus been applied and when most of the production would have gone for export with the relatively enormous prices that were ruling outside the United Kingdom. There has been but little recognition of the amount the British farmer gained from the control over fertilisers that was exercised from 1917 onwards.

Little need be said about the steps that were taken to ensure the supply of seeds and other articles of agricultural consumption. The most striking result was the way in which the great dearth of seed potatoes from the 1917 crop was met. More than 15,000 tons of seed potatoes were distributed in England and Wales, and, above all, the newly-formed allotments that had been so eagerly taken up in that year were furnished with the seed potatoes they needed. The opportunity was taken early in 1917 to enforce a declaration of germinating capacity and purity of all seeds sold; and this action, necessitated at the time by the scarcity of material and the resulting commercial temptation to sell inferior seed, so commended itself both to farmers and the trade that it was embodied in a permanent fashion in the Seeds Act of 1920.

Allotments.—In no respects perhaps was the Food Production Department more successful in helping out supplies than in the stimulus and assistance it gave to the creation of allotment gardens, particularly in urban centres. The powers conferred upon the Department by D.O.R.A., which were delegated to town and urban district councils, enabled them to take possession of any unoccupied land for the purpose of letting it as allotments, and even of cultivated land with the sanction of the Agricultural Executive Committee. These powers were freely exercised, and perhaps an equal amount of land was made available for allotments by voluntary agreement. Because of these private agreements it will never be known exactly how many allotments were provided during the war period, but over 250,000 were added in England and Wales under the D.O.R.A. powers alone, and so rapid was the further growth that it was estimated in 1918 that the total number of allotments had been more than doubled. On the outskirts of all large towns the new movement was very much in evidence in the spring of 1917; unoccupied land of all kinds, building plots, waste land awaiting development, portions of commons, even parks and recreation grounds, were being divided up into plots of a sixteenth of an acre and hastily prepared for growing vegetables. It was often late in the season before the work began, particularly for heavy land such as the clays round London, but fortunately the season proved favourable and good results were obtained for the zeal and energy which had been put into the cultivation of what was often very unpromising material. The Food Production Department assisted in the supply of seed potatoes and other supplies; advice and instruction were organized in conjunction with the Royal Horticultural Society, which enrolled the professional gardeners everywhere into a panel of voluntary instructors. It was estimated that by 1918 the number of allotments had increased in England and Wales from something like 800,000 to over 1,200,000, and the increase was continued after the Armistice. The number relative to the population varied considerably, but in and about Leicester there was an allotment to every three households.

The benefit of the allotment movement to the community is difficult to overestimate. There was in the first place the actual addition in the food supply, which in England and Wales alone was set at 800,000 tons of food in 1918. This home-grown supply without doubt helped to steady prices in 1917. Again, the growth of fresh vegetables by urban populations, who under the prevailing conditions would have had some difficulty in buying them, contributed a very valuable factor in a war-time dietary. The development of allotments did contribute to keep down the growth of deficiency diseases like scurvy and probably of tuberculosis, to which the food conditions of 1917–8 were favourable. Lastly, very many people obtained a considerable relief from the war strain by the physical exercise in the open air and the new interests developed by their allotments. To many people the war-time allotments revealed a deep-seated pleasure in the cultivation of the land, which had been obscured to them by

residence in a town, and the strength of this feeling was made manifest by the widespread movement that grew up after the war for the retention and extension of the allotment gardens.

Of course, the close of the war necessarily led to the displacement of many of the allotments which had been formed on land that could only be temporarily allocated for the purpose. Much of it had only been handed over on private agreements and was resumed for building or other industrial purposes. Recreation grounds and park lands could not be permanently alienated from the enjoyment of the general public. Even land which had been occupied under the D.O.R.A. powers of the Board, and of which possession could be retained until March 23 1923, had often to be given up because its retention would have involved enormous claims for compensation when the land was immediately required for building purposes. Widespread as was the demand for security of tenure in allotments it was impracticable either to gratify it now, or to repair the want of foresight when the great towns were growing, by making allotments at the expense of the community on land which had already acquired a building value of £1,000 an acre or upwards. It might still be possible to provide for allotments on such land while it was vacant and awaiting development, but only on condition that the occupiers would have to be prepared to move on at comparatively short notice when building became imminent. Many authorities in 1921 were exercising with considerable forethought their powers to acquire land for allotments, and were acquiring land conveniently accessible outside the zone of immediate development. Round many cities and towns a belt of allotment cultivation could be seen to be extending, though the cultivators might actually live at some considerable distance in the thickly populated inner area.

Incidentally the Agriculture Act of 1920 gives an allotment-holder compensation for disturbance on similar lines to that enjoyed by occupiers of larger buildings.

The growth of the allotment movement may be measured from a very full inquiry that was made of the numbers at the end of 1920. According to an early return in 1890 there were then 448,586 allotments in England and Wales of under one acre, to which should be added certain railway allotments estimated as 39,115 in 1886.

At the end of 1920 the numbers in England and Wales were as follows:

	No. of allotment holders	Acres
Land managed by county councils under Act of 1919	329,471	46,963
Land entered upon by councils under D.O.R.A.	198,299	14,369
Land occupied by councils and used temporarily under D.O.R.A.	56,456	4,141
Other land used as allotment	598,157	95,754
Totals	1,182,383*	161,227

Owing to the fact that in six cases the allotment land was let to associations of allotment-holders, the gross total of holders should be increased to about 1,330,000. It should be noted that one-half in numbers and considerably more than half in acreage of the allotments in England and Wales were still provided in 1921 by private owners.

Control of Agricultural Prices.—The pressure of the war and the increasing difficulty in obtaining supplies necessitated a resort to the fixing of prices for agricultural commodities, which materially affected the business of British farmers during the critical years from the beginning of 1917. The Food Controller was appointed in Dec. 1916, and the Act under which he was appointed gave him very complete powers to fix the prices of commodities and to take over stocks, to control distribution and otherwise deal with all articles of food produced within or entering the country.

As might be expected, considerable discussion and differences of opinion arose as to the methods to be adopted in dealing with agricultural produce. From the crudest point of view the Food Controller might be taken as the agent of the vast majority of consumers, anxious therefore to reduce prices, whereas the Departments of Agriculture would be regarded as the guardians of the interests of the agriculturists. Such an opposition of interests was, however, rarely allowed consciously to weigh. The divergences of opinion grew from the fact that the Agricultural Departments were more seized with the necessity of increasing production, and apprehensive of the way in which restrictions upon price might so interfere with the business of the farmer as to limit the total output of food. It may be useful to put on record some of the results of the control and the effect they had upon the course of production.

During the years 1917–9 control was exercised over the prices of all the main articles of agricultural produce—grain, meat, milk, cheese and butter, potatoes, eggs, fruit, certain vegetables, wool and hay, though in the two latter cases the control was exercised by the War Office and not the Food Controller. Two ends have to be satisfied in the control of prices of agricultural produce. Primarily the public have to be protected from excessive rises of price, due primarily to the scarcity and then to the speculation and repeated dealings amongst the middlemen that inevitably follow. The farmer himself, the prime producer, is rarely in a position to take advantage of the public need and, in the current slang, "to profiteer." The conditions of the farmer's business are such that he is waiting on the price that is offered to him in the open market. Most of his output consists of perishable materials which must be sold forthwith, and he is rarely united into associations that are capable of exercising any pressure to refuse to sell below an agreed price. The rapid enhancement of prices that follows scarcity is as a rule the work of the dealers between the producer and the consumer, and the farmer is but a passive recipient of the share that accrues to him through the competition of dealers for his produce.

The second end to be attained in price control is the encouragement of production. It is possible to fix a price in the interests of the consumer which may be regarded as leaving a fair margin of profit to the producer, but which is followed almost immediately by a restriction in supply. High prices are of course an evil from the point of view of the consumer, but in times of scarcity it is more important to get the food in quantity than to get it cheap. It becomes necessary, therefore, to fix such a level of prices as will encourage the producer to make a special effort to increase his output, and to this end it is never possible to base the price upon the average cost of production of the article. It is necessary to stimulate the production of the poorer farmers, whose skill may be inadequate or who are working under comparatively unfavourable conditions. As a consequence it follows that the prices will be such as give excessive profits to the more favourably situated producers. This is specially marked in dealing with agriculture—an industry which in the main is carried on by individuals working upon a comparatively small scale, an industry in which the processes are not standardized and for which accounts showing the actual cost of production are very rarely available.

Considerable feeling was at times engendered against the farmers in Great Britain on the ground that they were making very large profits out of the public need and the restriction of supplies, but looking at the question broadly, these excessive profits accrued inevitably to the men who by their skill or their situation were capable of comparatively cheap production.

From time to time attempts were made to establish systems of differential prices, according to districts. This was tried, for example, with milk, on the ground that the south-western counties could, as a rule, produce milk at a lower price than the mass of the country. Again, in 1918 differential potato prices were established by districts, according as they were regarded as adapted or otherwise to potato-growing on a large scale. Speaking generally, these differential prices proved to be comparatively ineffective and were the cause of great discontent and opposition amongst the producers. The main difficulty lies in the definition of districts within which the conditions of production are equal. County boundaries do not represent uniform conditions of soil and climate. The object could only be rightly attained by the scheduling of individual farmers into different classes and that is administratively impossible.

As a rule, the method of control adopted was to fix a maximum price beyond which the article must not be sold, and to enforce this maximum price by the action of inspectors. It was found in all cases of real scarcity that the maximum price became a minimum, and that the control amounted to the fixing of a flat rate of price for the article all over the country. Maximum prices having been fixed, there are then two alternatives: the Government may become the sole buyer of the commodity, or it may still leave distribution to the ordinary channels. It was found by experience that the Government can only become the sole buyer when it also controls the consumption of the article. The main examples of this type of action during the war period were wool and wheat. In the case of wool the Government held the whole stocks, both of foreign and home-grown wool, and made its allocation from these stocks to the manufacturers for defined purposes. In the case of wheat the Government assumed control of all the flour-mills and instructed them to accept delivery of the farmers' wheat at the fixed prices.

Where the processes of manufacture and distribution are not so simple, as in the case of wheat and wool, the method of making the Government the sole buyer of the output resulted in excessive administrative difficulties. An example is furnished by the potato crop of 1918, which on Nov. 1 was taken over by the Ministry of Food. The difficulties were accentuated by the fact that the crop was a large one, rather more than the demand would normally call for, and that it was not as sound as usual, so that in many cases the whole or part of the crop perished in the farmers' clamps before it could be distributed. Under normal conditions the farmer who has potatoes of inferior keeping powers makes a sacrifice in order to get them away rapidly. He also looks the crop over from time to time and rejects potatoes that are becoming diseased and therefore dangerous to the bulk of the crop. Once, however, the crop had passed into the Government's hands, the farmer naturally ceased to exercise the same care in handling it. The result in this case was a dispute as to the responsibility for the losses that occurred. The Ministry on the one hand alleged that the losses had been due to the initial unsoundness of the crop, for which the farmer must bear the responsibility. The farmer, on the other hand, alleged that had he remained in control he could have disposed of the crop and that the losses were due to the Government's delay in moving it to the consumer. When the Government attempts to replace by a new official organization the intricate machine which custom has built up for the distribution of any general article of consumption, the result is confusion and increased cost. The "trade" machine may be intricate and illogical, but it has been in the habit of working and it has been shorn of waste by competition.

If the Government does not constitute itself the sole buyer of the production, it yet follows that it must assume the control of distribution as well as of prices. Under normal conditions it is only by the offer of a price above the average that any locality distant from the source of supply, or otherwise unfavourably situated, can attract to itself the supplies that it needs. With a flat rate of price the producers will endeavour to sell as near home as possible. The near localities would thus become abundantly or even over-supplied, while the distant localities would have to go without. Not only must the Government control the distribution, but also it must fix prices all along the scale between the producer and the consumer. It is not sufficient to fix retail prices only to the consumer, nor, at the other end of the scale, producers' prices only. It was, therefore, found in practice necessary to fix both the price to the consumer and to the producer, and also the percentage that could be taken by each middleman in handling the commodity. This inevitably resulted in an increased margin between the prime cost obtained by the producer and the price finally paid by the consumer, because all the intermediaries between the producer and the consumer established their claim to a commission, whereas in practice some or other of them are generally cut out by competition, or have to take a lower toll than that for which they are able to make out a case.

Speaking generally, when a Government has to make a bargain, either with producers about price or with the members of a trade for their services, it fails to get good terms. The accounts of the weaker producers or agents are always put forward, and the price is determined according to their needs and their expenditure. Moreover, the parties always deal in terms of round pennies and round shillings, whereas in normal working profit and loss is determined by eighths or sixteenths one way or other.

The main difficulty, however, that besets the control of agricultural prices arises from the alternative nature of the farmer's business. As a rule he has more than one way of disposing of his produce. For example, he may find it more profitable to turn his wheat into food for hens and sell eggs or poultry than to sell the wheat itself. He has the alternative of selling his barley crop or grinding it into meal and feeding pigs with it. His milk can be sold as such or converted into butter, cheese or veal, according to which offers the greatest prospect of profit. It therefore follows that for no article of agricultural produce can the price be fixed without reference to the prices ruling for other products which may from the farmer's point of view be alternative. The farmer may even—though this is more difficult and acts more slowly—vary his method of dealing with the land. For example, at the time when the land was most in need of corn production and the Food Production Department was engaged upon a strenuous campaign to extend the area of arable cultivation, the farmer was able to obtain much greater profits from the production of meat and milk on grass land than from corn upon arable land, because a proper parity had not been established between corn and meat. In fact, the fixing of prices of agricultural produce should be preceded by a scientific examination of all alternative conversions of one product into another which are possible to the farmer. It is possible to construct a scale of parity which shall show the price relationship of such diverse articles as hay, corn, meat, milk and milk products. Prices should then be fixed in accordance with this scale of parity, weighting those articles which it is desired to produce in the general interests of the community by giving them a rather better price than the scale of parity would indicate.

The neglect of this principle led to many difficulties and much discontent in particular cases. For example, in 1918 the prices at which the British farmer was called upon to sell his wheat, oats and barley were a good deal below the prices at which he could buy other articles of cattle-food on which to feed his stock. The farmer was forbidden to use wheat and barley for stock if it was sound and fit for milling. On the other hand he could buy no feeding-stuffs so cheap, and corn which had been damaged in harvesting or was otherwise unfit for milling purposes was more valuable to the farmer as stock food than the price fixed for sound corn. Inevitably this state of things led both to carelessness in harvesting and storing corn and to a certain amount of evasion of the order forbidding the use of sound corn for feeding stock. That the extent of the evasion was not greater was due to the general state of public opinion at the time, but a more careful consideration of the question of parity of prices would have removed the temptation and resulted in more corn being available for the general public. Another example may be seen in the case of butter. It takes from 2½ to 3 gallons of milk to make a pound of butter, yet for various reasons at the time when milk was selling at 2s. a gallon or even higher prices, the price of butter was fixed at 2s. 6d. per pound. The result was the almost complete disappearance of home-made butter from the market.

A still more noteworthy example of the difficulties arising from price fixation and the alternative use of products is supplied by the later dealings with milk. Prices of milk were fixed at six monthly intervals from 1917 onwards and rose steadily from year to year as the shortage of labour and the cost of feeding-stuffs increased. The prices fixed were without doubt remunerative to the great majority of dairy farmers, as can be judged from the expansion of cow-keeping and the abnormal rise in the price of dairy cows. Eventually when winter prices were fixed in the autumn of 1919 the public definitely revolted and the demand for milk declined all over the country. The season was also such as to produce an unexpected abundance of milk. All wholesale milk-supply businesses must possess some alternative means of utilizing milk and generally adopt cheese-making in order to deal with their occasional surpluses. The Ministry of Food, in its anxiety to encourage winter milk production and yet unable to fix a cheese price in parity with the price of milk, had adopted the expedient of offering an allowance to wholesalers for all cheese made in the autumn months. With the refusal of the public to buy milk freely this cheese grew into quantities altogether beyond anticipation; at the same time the allowance did not make up for the wholesalers' losses on the contracts at maximum prices they had made with farmers. The situation became impossible, and eventually early in 1920 control had to be abandoned, with the result of a general breaking of contracts and a smart fall in price. A system of control of prices which will work well enough and secure even distribution during a period of scarcity lacks any power of adjusting itself to the other situation, which is always liable to arise, of supply outrunning demand. The public sooner or later revolts at the price, whereupon the producer demands from the Government a market as well as a price.

The establishment of fixed prices, by obliterating the variations which under normal conditions meet variations in quality, causes the deterioration of the general average of quality. Various examples were seen of this operation of a flat price. For example, in 1919 the finest grade of Cox's orange pippin apples had to be sold at prices below that which they normally obtained in pre-war times, because the maximum price for dessert apples, high as it was in comparison to pre-war prices, still made no allowance for the choicest grades. Nor is it possible under such conditions to remove these special articles from the control. If there are two prices the retailer immediately removes the whole of his wares into the higher category and the consumer is faced with the alternative of paying the higher price or going without.

Another example of the effect of the flat rate of price might be seen in the general deterioration of quality of all kinds of cheese made during the war years. The producer could get no higher price for fine quality, and since storage and therefore the development of flavour is inevitably accompanied by loss of weight, the cheese was sold as quickly as possible without regard to its quality. Again, the fixing of a flat rate of price for mutton and lamb of all kinds resulted in a great diminution in the number of sheep kept upon the arable land, like the South Downs and the Hampshire Downs. These flocks derive their returns chiefly from the sale of lamb at comparatively high prices, but when the extra price for lamb was unobtainable with their more expensive methods of production they became unprofitable. Between 1913 and 1919 the numbers of sheep in England and Wales taken as a whole declined by 11·7%, but the flocks in predominantly arable counties like Hampshire, Wilts and West Sussex lost about 40% of their sheep. The decline in sheep fell in the main upon the arable land sheep because they could no longer obtain the normal differential prices for their output.

One general conclusion may be drawn from the operations of controls during the later years of the war, a conclusion strengthened by a consideration of the parallel events in Germany and France where the pressure was greater—that State action has very little power to compel agriculturists to conduct their businesses along lines contrary to the interests or traditions of the farmers themselves.

For example, numerous orders and regulations were promulgated from 1914 onwards forbidding the slaughter of calves, even

to the extent of closing the markets to the sale of calves for slaughter and of forbidding the sale of veal. Though the measures had the approval of all the farmers' organizations they were systematically evaded and were wholly without effect in checking the increasing slaughter of calves. Again, the orders that forbade the use of barley and wheat for feeding stock in 1917 and 1918 were not observed whenever the farmer was in any real difficulty about getting food for animals. No farmer will see live stock starve and the agricultural conscience was salved by a consideration of the extraordinary mixtures of waste material that were being purveyed as cattle-food at higher prices than the farmer was allowed to receive for his sound wheat and barley. Again, in the rationing of the self-producer, the regulations declaring that a farmer might only retain so many of the pigs he killed at home, or so much of the poultry, milk, butter or cheese he produced, were simply ignored. It is impossible to enforce such regulations except by a system of espionage and inspection that is impossible in war-time for lack of men. Rationing was carried out most successfully in Great Britain, and the great force behind it was the public sense of its need and the feeling that it was being administered with perfect fairness and no favour. Nor was the pinch of scarcity ever severe enough to break down the general *moral;* the people at large did feel hungry and were irked by the restrictions in their diet, but they could carry on and were not impelled to illicit traffic in order to obtain food. But since the farmer saw no dire need he felt no particular compulsion to change his ordinary way of living. It is not that the farmer is less patriotic than his fellow-men, but the war was far away from his countryside, and he is an individualist by temperament and habit, less subject to the crowd suggestion that draws the city dwellers into a common action, and with his accustomed routine as the most compelling factor in his psychology.

Should the occasion ever again arise it will be well to recognize that the agricultural community cannot be driven or subjected to the external control that proved successful enough with other industries; it must be organized from within to coöperate with the State. In this particular case agriculturists felt that their importance to the nation had been ignored in the early years of the war, and when the time came to regiment them in the common effort there was always a tinge of opposition in their attitude to the measures that were then forced upon them.

Speaking broadly, it may be said that, whatever criticism may be passed on the working of the control of prices in the United Kingdom during the war period, whatever may have been the defects in the system that have been noted above, these faults were inherent in the nature of the task and were not products of the administration. The farming community often felt itself oppressed, the consuming public often regarded itself as exploited, individual hardships were inflicted and in other cases ill-deserved profits were lightly piled up, but the control did work and did prevent an intolerable state of war between consumers and producers. Control there had to be, and one may look back upon it as a reasonably successful improvisation, characterized by the national qualities of fair play and compromise.

AICARD, JEAN FRANÇOIS VICTOR (1848–1921), French poet and dramatist (*see* 1.434), published after 1910 a collection of poems for children (1912) and *Hollande, Algérie* (1913), as well as various volumes of war poetry, a novel *Arlette des Mayons* (1917), and two volumes of adventure stories, *Un Bandit à la Française* and its sequel *Le fameux chevalier Gaspard de Besse*, both in 1919. He died in Paris May 13 1921.

AINLEY, HENRY (1879–), English actor, was born at Leeds Aug. 21 1879, and was educated for business; but a meeting with George Alexander and an engagement for a "walking-on" part turned his thoughts to the stage, and he joined F. R. Benson's touring company for two years. He then appeared at the Lyceum theatre, London, in 1900 as Gloucester in *Henry V.*, and in 1902 at the St. James's theatre as Paolo in Stephen Phillips's *Paolo and Francesca*. He played Orlando in *As You Like It* both at the Comedy theatre in 1906 and at His Majesty's theatre in 1907. In 1910 he appeared there again in many Shakespearean parts, and in 1914 he played Leontes and Malvolio in Granville Barker's production of *The Winter's Tale* and *Twelfth Night* at the Savoy theatre. After serving during the World War he began management at the St. James's theatre with Tolstoy's *Reparation* in 1919, following it up by a production of *Julius Caesar* early in 1920. In 1921 he played Prospero in *The Tempest* at the Aldwych theatre, and John Beal in Lord Dunsany's *If*.

AIR BOMBS.—Although the Hague declaration of Oct. 18 1907 contained a clause prohibiting, for a period extending till the next peace conference, the "discharge of projectiles and explosives from balloons or by other new methods of a similar nature," this declaration was only ratified by Great Britain, Austria-Hungary, the United States and Turkey. France, Germany, Italy, Japan, Russia and Spain did not sign it, and it was therefore regarded as "practically without force" (British official *Land Warfare*, 1912, p. 24). The only limiting condition of aerial bombardment was, therefore, that applying to all bombardments, viz.: The prohibition of bombardments of undefended localities. The word "undefended" was not more closely defined; and it could be, and by some far-seeing authorities was, presumed that aerial bombardment of localities would certainly figure as an element of the "next Great War."

In the article AIR DEFENCE will be found an account of the principles of defence against air bombardment, as they were evolved in the World War of 1914–8. The present article deals with the bombs themselves, as material weapons, and with their accessories.

Projectiles dropped from aircraft, officially termed "Aerial Bombs," may be classified as High Explosive Bombs (H.E. bombs), Incendiary Bombs, and Bomb Parachute Flares.

1. High Explosive Bombs.—The principal use of H.E. bombs is to destroy material of all kinds; they are also used occasionally against personnel. They are a species of common shell, but differ from gun shells as, owing to the absence of shock of discharge, their envelopes require less strength, and consequently the proportion of weight of charge to weight of projectile is higher. With regard to their striking energy, bombs and gun shells, when fired at high angles, are comparable; but the striking energy of low-trajectory gun shells, other things being equal, is far beyond that of bombs dropped even from an extreme height. The field of action of a bomb is not restricted, as is that of a gun shell, by its extreme range, but depends upon the flying capacity of the aircraft employed; but the ballistic conditions under which a gun is used give an accuracy of fire which, in the case of bombs dropped from aircraft, is reduced to a minimum.

High explosive bombs are classified as *Light Case* and *Heavy Case.* Light case bombs, pear-shaped receptacles of mild steel, weighing when filled from 16 lb. to 100 lb., were made in great numbers in the early years of the World War. They were all of the same type. The case was made in two parts; the heavier, the nose end, was a hemispherical casting; the body was conoidal, tapering towards the tail end and the two parts were joined by an angle steel ring. In the 65-lb. bomb, for example, the nose end was ·25 in. and the body ·064 in. thick. As time went on the type developed; fig. 1 shows a

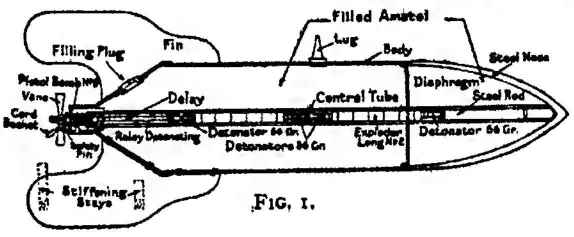

FIG. 1.

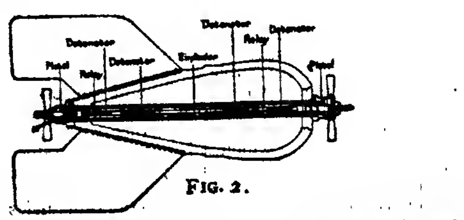

FIG. 2.

230-lb. bomb made of mild steel, ·128 in. thick in the body and increasing to ·375 in. in the nose. It carries 140 lb. of 40/60 amatol;

Light case bombs have practically no fragmentation and depend for effect on their charge alone. Heavy case bombs are made of single castings of steel or iron such as the *heavy case 112-lb. bomb* shown in fig. 2. Its cast-iron body varies from ·5 in. to 1 in in thickness and it carries about 28 lb. of 80/20 amatol. The fragmentation of these bombs is of the highest importance.

Bombs are usually provided with a central tube running their whole length, fitting into screwed sockets for which the bomb is tapped at nose and tail, except when the bomb, like the light case 230-lb. bomb, is provided with a sharp nose, when a tail socket alone exists. This central tube is divided into two parts by a steel ring called the *diaphragm* for convenience in loading and keeping components in their place. In the *heavy case 20-lb.* and *50-lb.* bombs, the tail is prolonged outside the bomb proper by a light construction called a *fairing*, to provide a suitable shape for aerial flight. The 20-lb. bomb is peculiar in having only a nose socket and in the shape of its central tube. *Lifting lugs* are attached to many bombs. They are made of wrought iron and are riveted to the case so as to be in the same vertical plane as the centre of gravity of the filled bomb, when the latter is suspended in a horizontal position. At first bombs were released when horizontal; but now they are frequently suspended vertically from an eyebolt attached to the nose fuze or screwed into the nose socket. When a bomb is thus released it turns over in flight and falls nose first. *Lifting bands* of steel are sometimes used in place of lifting lugs. Four *vanes* or *fins*, placed in quadrature, are riveted to the case of all bombs about the tail end, to ensure steadiness in flight. The interiors of bombs are varnished or lacquered; they are then filled with high explosive.

High Explosives used in H.E. Bombs.—Trinitrotoluene, known as trotyl and T.N.T., is used as the main charge of a bomb or as a topping to a charge of amatol, which on account of its hygroscopic nature has to be protected from damp. T.N.T., when compressed into pellets, is also used in exploders and relays. Amatol is used as a main charge for bombs. It is a mixture of ammonium nitrate and T.N.T.; at first it consisted of 40 parts ammonium nitrate and 60 parts T.N.T. (40/60 amatol); later on, 80 parts ammonium nitrate and 20 parts T.N.T. (80/20 amatol) was the mixture adopted. Tetronitromethylaniline, known as tetryl, Composition Exploding or C.E., when compressed into pellets is used in exploders and relays. Fulminate of mercury is used for detonators.

Bomb Components.—Bomb components consist of fuzes, exploders, relays, detonators and igniters. Those selected for a given purpose are called an *assemblage*. The assemblage varies with the bomb and the purpose for which it is to be employed; but in every case an H.E. bomb is detonated on impact by the action of the striker of a fuze, which explodes a cap or patch of cap composition, detonating a relay or exploder, which detonates the main charge of the bomb. Exploders are hollow cylinders of sheet brass or paper filled with compressed pellets of T.N.T. or C.E. They are provided at one or both ends with metal envelopes or sleeves for the reception of the particular detonator with which they are to be used. Exploders vary in length and other details. Relays are exploders of a special kind, usually filled with pierced C.E. pellets; they are always next the fuze, to which they are sometimes attached by screwed thimbles called *adapters*.

Detonators are copper tubes of various sizes and are charged with from 45 gr. to 60 gr. of fulminate of mercury according to the use for which they are intended. When they are to be fired by a striker they are closed by a cap. Igniters are a special form of detonator, which carry between their charge and the cap a piece of match designed to cause a certain delay (up to 15 secs.) between the moment of impact of the bomb and its explosion. The match composition consists of nitrates and chlorates of potash, etc., mixed with shellac and methylated spirit.

Fuzes.—Both nose and tail fuzes are provided for H.E. bombs. The former are all on the percussion principle and are usually called direct-acting fuzes (D.A. fuzes). The first to be used by the British was a modification of the No. 18 gun percussion fuze made for a tapered fuze hole. The motion of the striker, however, was controlled by a collar carrying two small vanes, called arming vanes. The vanes rotated as the bomb descended, eventually screwing the collar off the striker and leaving it free to act in the same way as it would in No. 18 after undergoing the shock of discharge when fired in a gun. A tapered fuze hole being found an unnecessary refinement in the nose bushes of bombs, the latter were tapped cylindrically and fuzes with corresponding threads were adopted. The latest development is the D.A. pistol (see fig. 2) which is an ordinary percussion fuze fitted at the top with a cover to which the vanes are attached, as is also a hanging eyebolt for the suspension of the bomb. At the bottom end the fuse is attached by an adapter to a detonator and relay and the assemblage thus complete can be screwed into the bomb. In certain special nose fuzes the action of the vanes is utilized to screw the striker into position. Safety devices exist in all fuzes. Tail fuzes are all of that type to which the term pistol was originally given. (See figs. 1 and 2.) The striker at its upper end terminates in a screw upon which works a collar with vanes attached. As the bomb falls the collar screws off and releases the striker, which is then only held in position by a spiral spring; on impact this spring is compressed and the striker is forced down upon a cap which explodes the bomb. If desired, however, a match burning a certain number of seconds may be interpolated between the cap and the charge, thus forming an igniter which secures the desired delay action.

When a nose fuze is employed the striker is on impact driven on to a detonator which causes a practically instantaneous explosion; but all tail fuzes must of necessity have a slight delay, for they only act after the speed of the bomb has been reduced considerably by meeting with some serious resistance, and this results practically in a delay of at least a quarter of a second, which delay can, as already explained, be extended up to 15 secs. by the use of igniters. It is evident, therefore, that a bomb set in action by a nose fuze has no chance of penetrating a target before explosion takes place; there is but a small crater formed and fragments of the bomb are scattered over a wide area. A nose fuze, therefore, is used with heavy case bombs in the attack of personnel and light structures, such as aeroplanes in transit, where crater effect is not required. With tail fuzes, on the contrary, bombs falling in suitable ground will bury themselves before exploding, producing considerable craters but scattering no fragments. Tail fuzes in connexion with light case bombs are therefore employed in the attack of railways, dumps, buildings, and for general local destruction.

In the attack of certain buildings a combination of a nose and tail fuze is adopted. The shearing pin of the former is such as not to be broken as the bomb passes through the roof, while the tail fuze has a delay which will cause an explosion inside the building. If in such a case a tail fuze only were used, should the bomb break up on impact, the delay action might entail incomplete detonation or there might be no detonation at all. When bombs are made of cast iron both nose and tail fuzes are always employed.

Carriage of Bombs.—Filled bombs are stored with all sockets, etc., plugged; components are packed in their own receptacles. Before the various detonators, relays, fuzes, etc., which constitute the assemblage, are inserted in the central tube of a bomb, the latter is tested in the dropping gear; when all is proved to be satisfactory the bomb is made "live"; but all safety devices are kept in operation till the moment of ascent. If a machine lands with bombs unexpended, all safety pins and other devices are made operative before the bombs are removed from the carrier.

Sighting of Bombs.—If a machine be flown directly on a target at a known constant height and with a known constant speed, a sighting apparatus can be employed from which, however, accurate results cannot be expected. Its use depends upon the following theoretical considerations: a bomb, when released, will continue to travel with the velocity of the machine and will pass over a horizontal distance before striking earth, which will depend on this velocity and the time taken to fall from the height at which the machine is flying. If then a right-angled triangle be formed with an altitude equal to the given height and a base equal to the horizontal distance passed over by the bomb, the slope of the hypothenuse will give the direction of the line of sight which must be employed.

The sighting apparatus is fitted with a horizontal wire which acts as a foresight and with three other similar wires which act as backsights, each for a given speed and height. Thus an observer using the backsight will have his line of sight so directed that when it passes through the target he knows he must release the bomb.

The heights and speeds provided for are: a height of 6,000 ft. and a speed of 90 m. an hour; a height of 10,000 ft. and a speed of 80 m. an hour; a height of 15,000 ft. and a speed of 70 m. an hour. The foresight is capable of fore-and-aft movement by which corrections for wind and density of the air can be given. Two fore-and-aft wires in the apparatus, placed vertically one over the other, serve in preserving the proper direction of flight.

Typical Bombs.—The following are typical bombs for the purposes named:—The 20-lb. is a small heavy case bomb, capable of carriage by light machines; it is used in the attack of personnel, aerodromes and road transport. It is made of steel, its actual weight being 24 lb.; it will take a charge of 4 lb. 9 oz. of 40/60 amatol or 4 lb. of 80/20 amatol. The 50-lb. bomb is a medium heavy case bomb for general use especially against material, and can be carried by the smaller bombing machines on long-distance raids. Its actual weight is 49½ lb.; it carries a charge of 10 lb. 80/20 amatol; it is made of cast iron, ½ in. thick in the body and ¾ in. thick at the nose; the overall dimensions are 28½ in. long by 7 in. maximum diameter. It is sometimes carried vertically slung from the eyebolt of the nose fuze, sometimes horizontally when it is attached to the dropping gear by means of a steel band. The 112 lb. bomb is a larger heavy case bomb (see fig. 2) used for similar purposes in larger machines. The 230-lb. bomb is a large light case bomb, used for crater production in the attack of railways and buildings (see fig. 1).

In addition to these types of bomb, special bombs have been designed for special purposes. Thus the 336-lb. bomb was designed to effect demolitions by the distribution of heavy fragments. It carried a bursting charge of 70 lb. of compressed T.N.T. and the body was built up of bulged segments of steel 1 in. at their thickest parts. The 180-lb. bomb was designed as an armour-piercing bomb. It consists of a pear-shaped steel case varying in thickness from ·9 in. to 3·3 in. from tail to nose, being provided with a cap of mild steel on the same principle as a capped armour-piercing projectile for a gun, and carrying a bursting charge of 20 lb. of 40/60 amatol or T.N.T.

A light case 520-lb. bomb has also been made for easier production and for use against submarines. When used in the latter capacity it has a special fuze to obtain "depth-charge" effect, a purpose for which the 65-lb. bomb was used in the early part of the World War. The actual weight of this bomb is 525 lb. and it carries 340 lb. of 40/60 amatol. There is also a heavy case 550-lb. bomb, with a body of cast steel varying from ·75 in. to 1·5 in. in thickness; it carries 180 lb. of 40/60 amatol.

As carrying power is developed, bombs tend to become larger: thus in a recent professional lecture (see *Journal of the Royal Artillery*, March 1921) a bomb of 1,650 lb. was spoken of, and even heavier types may be seen in the near future.

2. *Incendiary Bombs.*—In British bombs of present make the following compositions are used:—Thermalloy, which consists of 90 parts magnetic oxide of iron, 27 parts aluminium and 25 parts sulphur; thermite, which consists of 76 parts magnetic oxide of iron and 24 parts aluminium; phosphorus; carcass composition, which consists principally of ground saltpetre, to which is added ground sulphur, sulphide of antimony, black powder and powdered aluminium, mixed with powdered resin, tallow and turpentine. The special match composition for igniters in incendiary bombs is approximately 34% chlorate of potash, 30% iron filings, 5% each of powdered aluminium and nitrate of barium and 26% shellac and methylated spirit.

The following are typical incendiary bombs:—The modified carcass bomb is made of tin plate, its overall dimensions being 19½ in. long by 5 in. maximum diameter. It is tapped at the tail for a pistol. It carries 3½ lb. carcass and 13½ lb. thermalloy composition, the total weight of bomb and pistol being 23½ pounds. It has two lifting lugs and is carried horizontal. During the loading of this bomb a former is employed to preserve the necessary cavity for the reception of the firing arrangement which consists of the *pistol*, the *special igniter* and the *adapter* and its *attachment*. The *special igniter* consists of a 28-bore Eley cap fitted with a copper sleeve containing a strip of instantaneous fuze, and the *adapter* is a screwed ring socket to which is attached a nozzle-ended celluloid tube loaded with 5 gr. of match composition. On preparation for action the igniter is pushed into the adapter, the latter is screwed on to the pistol which is then screwed into the bomb.

The caseless incendiary bomb is made of thermalloy moulded over an iron framework; its overall dimensions are 27·8 in. by 5 in. (side of square of maximum section). The total weight of the bomb is about 30 lb. of which 24½ lb. consist of thermalloy. The bomb can be stowed either in a vertical or horizontal position, and it is fired by a tail fuze and special igniter. It is fired in a similar manner to the modified carcass bomb, except that in addition to the pistol, special igniter and adapter, a length of instantaneous fuze is placed below the nozzle of the celluloid tube.

The baby incendiary bomb consists of three parts, the body, the cartridge and the cap or cover. The body is cylindrical and of thin plate tin, but is weighted at the bottom; in the centre of this weighted portion is placed a short pin or striker. A little above the latter are two suspending lugs for the cartridge, made by partially cutting out two small portions of the plate on opposite sides of the body and bending them inwards so as to form a support. The cartridge, which is of the ordinary sporting shape, has a percussion cap in the centre of the base and rests on the two lugs. The cap or cover is dome-shaped at the bottom, above which are three vanes with a circular disc on top of them. The assembled bomb weighs about 6 oz. and is about 6 in. long by 1 in. in diameter. The bomb is carried on the machine with the vaned cap downwards, but on release it turns over and falls with the vaned cap upwards. When falling from heights of over 30 ft. the lugs on which the cartridge rests are on impact sheared or bent sufficiently to permit it to set forward on to the striker, when the cap is exploded and the cartridge case ejected and the thermite ignited simultaneously. These bombs are always used in masses, and are packed in a special carrier which allows them to fall with a considerable spread; thus, to take a particular example, the 272 bombs packed in one form of carrier would, if released at a height of 5,000 ft., cover an area of 30 yd. by 80 yards. The carrier can be dropped complete if it is desirable to get rid of the bombs speedily, as in the case of a forced landing. With large bombing planes like the Handley Page, bombs can be distributed either by using several machines or by successive releases from a single machine. The small bombs provide a many-chance method of attack, which is not possible with the larger incendiary bombs, for with the latter a direct hit must be secured upon a combustible target and the chances are greatly against this combination being achieved. As, however, the small bombs descend in showers with a large spread and on impact further disperse their cartridges over the target area, the chances of a successful attack are considerable.

The 40-lb. incendiary and smoke bomb can be either burst on impact to produce a smoke screen or burst in air for the attack of kite-balloons, etc. It is made of tin plate ·025 in. thick and carries 30 lb. of phosphorus. Its overall dimensions are 1 ft. 10·75 in. long by 8 in. maximum diameter. It is tapped at nose and tail and has a central tube for a burster containing C.E. pellets and black powder. When used for smoke production a D.A. pistol is screwed into the nose and the tail is plugged, but when an air burst is required the nose socket is plugged and a special time fuze is screwed into the tail socket. The bomb when burst in air spreads out a shower of burning phosphorus over a circle of some 250 yd. in diameter. The lumps of phosphorus slowly burn out in falling and about half are used up in the first 2,000 ft. from the point of burst. If the latter be 3,000 ft. above the target the bomb will be practically lost. The special time fuze employed, the Medgally fuze, is set in action by a striker, normally held back by a spring in compression, which is released by a trigger when the bomb is dropped.

The Ranken Dart.—This dart, invented by Engr.-Com. F. Ranken, was used for the attack of Zeppelins and for other purposes. It consisted of a hollow tin cylinder, about the size of a large candle; the bottom was closed by a pointed bullet of steel or iron, and its top by a lid of tin through which passed a spindle capable of vertical movement and terminating at the end outside the dart in four flanges or vanes. The cylinder was filled with incendiary composition which was fired after the fashion of a Christmas cracker. For this purpose a strip of friction match had one end attached to the cylindrical body and the other to the spindle. Then if the dart fell upon a Zeppelin from above, its sharp bullet point would enable it to penetrate the outer covering upon which, however, the four flanges or vanes would catch; a jerk would thus be given to the spindle causing the match to be torn apart and ignited, and the dart, held fast in the cover of the Zeppelin, would burst into flames.

3. *Bomb Parachute Flares.*—These flares are used for reconnaissance at night, for illuminating and showing up ground held by the enemy, and for affording light to a pilot wishing to land in the dark. The flares are cylindrical paper tubes filled with aluminium composition and primed with magnesium composition; they are sometimes called candles. They are lighted by means of pieces of quickmatch attached to the primed end, the other end being fixed in a cup arrangement which is attached by a wire rope to the parachute.

Electric-Ignition Parachute Flare-Bombs are of two kinds almost similar in construction. One is used as a reconnaissance flare, the other as a landing flare to enable pilots to land in the dark. They are both launched by means of a launching tube attached to the fuselage of the aeroplane, and so designed that as the bomb leaves the launching tube an electric circuit is completed, and a platinum-silver wire bridge heated. This, by igniting a priming, sets a delay pellet in action and, after the bomb has dropped some 1,000 ft., a powder puff is fired, which both ignites the candles and projects the parachute clear of the cylinder. The reconnaissance flare (with a 9 seconds' delay pellet) burns for three to four minutes, weighs 6 lb. 13 oz., and has a parachute weighing 11 oz. and measuring about 5 ft. 6 in. across when open. The landing flare weighs 5 lb. 4½ oz., and has a parachute of the same size as the other but of lighter material, weighing only 3½ oz. The candles burn for from 2½ to 3½ min., and the delay pellet only gives one sec. delay so that the bomb opens after it has dropped some 20 feet. In both bombs the candle power is about 40,000. (J. R. J. J.)

German Air Bombs.—The general characteristics of air bombs being the same in all countries, British practice may be regarded as typical and foreign bombs need not be dealt with. Some notes on German air bombs are added, however, on account of the special interest attaching to these projectiles, which for the first time for many centuries brought war to the very doors of the British people.

The earliest types designed by the Germans were so far ineffective that as early as the spring of 1914 they were replaced by bombs of a type known as "Carbonite." These bombs, which were used throughout the earlier part of the war, were pear-shaped and solid, pointed, and had a propeller-actuated pistol of the same type as those described earlier in this article. Their special characteristic was the form of air-drag used: instead of fins, a sort of inverted tin cap was used, attached to the tail of the bomb by stays. The smallest of these bombs weighed 4½ kgm. (about 10 lb.), and the heaviest 50 kgm. (110 lb.). Small incendiary bombs of the carbonite type were also used. There was, further, a grenade-like projectile thrown by hand, which weighed 800 grammes (1¾ lb.), but this was criticized as being too small to be effective, as also was the 4½ kgm. H.E. carbonite bomb.

In 1916, these bombs were replaced by a different type known as "P. und W.," which continued in use to the end of the war. They were torpedo-shaped[1] and were fitted with slanting vanes which not only acted as an air-drag to keep the projectile nose down but also imparted rotation to the falling bomb, and so enabled the German designers to replace the propeller as an arming device by centrifugal bolts, on the same principle as those of gun fuzes. As the height at which bombs were released had by that time greatly increased, the additional time required for the arming of the fuze was of no importance. Time fuzes were also employed, chiefly for obtaining delay effects after impact.

The standard sizes of these "P. und W." bombs were the 12½ kgm. (27 lb.)—a thick-walled bomb with instantaneous fuze—and the 50, 100, 300 and 1,000 kgm. "mine" or thin-walled bombs, with bursters respectively of 23 kgm., 60 kgm., 180 kgm., and 680 kgm.

One other form of air projectile should be mentioned as, although it was never used on any large scale, it had a moment of notoriety

[1] Torpedo-shaped bombs were also used by the French, who named them "pisciforme" (fish-shaped) bombs, in contradistinction to "piriforme" (pear-shaped).

in the early stages of the war. [illegible] of steel sharpened to a point at one end. These darts, released in showers, were intended to be effective against personnel.

(C. F. A.)

AIR DEFENCE.—Even before aerial navigation and aviation had been developed to a practical point, the employment of aircraft in war for the attack of vulnerable places was discussed from time to time in a speculative way, and in the seven or eight years preceding the World War the types and characteristics of aircraft became so far definite that technical study could be brought to bear on the problem of defence, especially that of artillery defence. But this period of seven or eight years was short; military history could give no lead; practical experiments were almost impossible. Moreover, in the existing state of international law, liability to air attack was understood to depend not on whether a place was vulnerable, in the sense that its destruction would impair the capacity of the nation for carrying on the war, but on whether it was "defended," i.e. fortified in the conventional sense of the word, or at any rate held by a ground garrison against ground attack. Attention was therefore directed chiefly to the question of air attack on what according to the prevailing ideas were "military" objectives, and in view of the small numbers of aircraft then available such attacks were regarded as unlikely to affect the course of operations seriously.

In these conditions, and especially in the absence of all data based on practical experience, it is not surprising that defence against air attack was everywhere in a rudimentary state at the outset of the World War. In the war itself, on the contrary, experience, data and methods crowded upon one another from first to last, and through the clearer definition of the problems to be faced on the one hand and the constant process of trial and error on the other, it has become possible to formulate the main principles of air defence with some approach to precision.

I. General Considerations.

Air defence, as discussed in the present article, deals with the arrangements which deny to enemy aircraft access to vulnerable points. By "access" is implied the gaining of a position either directly over the objective or sufficiently close to it for the success of the attack. Amongst "vulnerable points" are included bodies of troops and their *matériel* in the field, centres of population, large magazines, arsenals, harbours, ports, dockyards, ships and convoys at sea, big industrial centres, and the like. As with a fleet, the primary duty of the air forces is to seek out the enemy air forces and destroy them; but the problem in the air is far more difficult than on the sea, as a third dimension has to be taken into account, *i.e.* that of height. When we remember what difficulties have been introduced into naval war by the introduction of the submersible warship, slow as this is and small as is its up-and-down range, and when we realize further that, in the air, opposing craft can pass at great heights both above and below each other, move at speeds that are enormous relatively to any rate of movement on or under the sea and have to cope with extraordinary difficulties in detecting one another's proximity, it will be seen that the task in front of the air forces of any nation is the most difficult of all.

There is no "command of the air" while the enemy disputes it. Therefore, against attacks by air, it is a logical necessity to provide ground defences, and to limit the radius of the air units allotted to coöperate with them. But though defence against attack by air, as on the ground, may be active or passive, yet to be effective it must be both. Further, the conditions under which aircraft move, by day and by night respectively, are so widely different, that the conditions of the defence must be correspondingly varied to meet them.

It is not intended here to deal with operations launched over long distances against enemy aerodromes and depôts, such being the rôle of the air forces alone, but solely with the local defence of areas occupied by "vulnerable points" of the kind which have been enumerated above.

The instruments of air defence are:—(*a*) the machine-gun on the ground; (*b*) the machine-gun in the aeroplane; (*c*) the [illegible] guns on the ground; (*d*) the searchlight, the sound locator, the observer post; (*e*) the aerial obstacle; (*f*) local protection on the ground, *i.e.* against bomb splinters and machine-gun fire, and camouflage.

Each of these weapons supplements a deficiency in one or more of the others; none is complete without one or more of the others acting in conjunction with it. From this it follows that, in any anti-aircraft organization, coöperation in effort can only be effected by organizing units of the air force, artillery and engineers under a single command, as in a formation of all arms in ground warfare.

The following are some of the forms which attacks by aircraft take:—bombing by airships, aeroplanes [illegible] in formation; [illegible] machine-gun [illegible] torpedoing ships at sea [illegible] escorted by "scout" (*i.e.* air-fighting) machines. To [illegible] be added, though they only indirectly affect the problems here discussed,—photographic or visual reconnaissance, by aeroplanes or seaplanes, singly; and aerial engagements, by aeroplanes in formation on hostile patrol, *i.e.* ready to engage air-fighting groups of the enemy, or by aeroplanes, singly or in groups, attacking machines which are engaged in observation duties (especially artillery observation) in connexion with ground operations.

Anti-aircraft units are concerned primarily with hostile attacks the objectives of which are on the ground or sea; the defence of objectives in the air is a secondary matter, but nevertheless important when air-force units are not at hand to undertake the duty themselves.

It may not be amiss at this stage to mention a few of the peculiarities of sound and light. Although these properties are generally known, their full importance in relation to air defence is seldom recognized by those who have little experience in anti-aircraft work. Sound travels at a certain known rate, namely about 1,100 ft. per second. Aircraft are generally first detected by ear. By the time the sound of a machine reaches the ear, the machine making it will have moved some distance away from the spot where it made the sound. A path of sound is deflected by the different velocities of the various air currents through which it passes on its way to the ground. A machine in the air is only visible to an observer on the ground by reason of light rays reflected from the surfaces of the machine, reaching his eye in sufficient intensity to enable him to detect it. Thus a machine flying "straight into the sun" is invisible to an observer also facing the sun. A spherical or cylindrical surface reflects light chiefly in the direction from which the illumination comes; hence, in the case of a balloon or airship, the observer sees the target best when he and a searchlight are on the same side of it. A flat surface reflects light towards an observer further from the source of illumination than its own position; thus an aeroplane flying steadily in a searchlight beam is generally seen best when it is between the observer and a searchlight. It does not follow that because aircraft are invisible to observers on the ground the ground is invisible to an observer in the machine, and *vice versa*. The greatest difficulty is frequently experienced in gaining the correct focus for the eye, and, having gained it, to maintain that focus. This is a difficulty common to the observer both on the ground and in the air, but whilst the former has only to look upwards, the latter has in addition to look all round and below his machine. Neither has the assistance of intermediate objects by means of which the focus of the eye can be altered and held at definite stages. By day the observer in the air is deaf, by night he is deaf and blind. A searchlight shining into the sky is only visible by reason of the particles of "dust" or moisture in the path of the beam. In a perfectly clear or clean atmosphere the beam is invisible.[1]

[1] Unusually clear atmospheric conditions with a few high clouds were responsible for popular rumours prevalent during the war in 1914–8, to the effect that a new invisible searchlight had been discovered which simply threw a disc of light far away up in the sky, and was otherwise quite invisible.

II. Conditions affecting the various Instruments of Air Defence.

(*a*) The *machine-gun on the ground*, on account of its comparatively short range, can only deal with targets flying at low heights, *e.g.* up to 3,000 or 4,000 feet. On the other hand, the ease with which it can be handled enables it to cope with the rapid change in angular velocity of low-flying targets in a way which the heavier guns cannot do. Low-flying machines move over their ground targets with a very rapid angular velocity, and owing to their small height they are often invisible from the ground objective until at a close range. Every unit of an army, therefore, requires anti-aircraft machine-gun equipment for its own local protection.

(*b*) The *machine-gun mounted in the aeroplane* can attack its target at close range, and, if its own aeroplane is superior to the target in speed and in climbing and manoeuvre power, can maintain that attack until the combat ceases. It is therefore of great importance in air defence.

Mention has already been made of the difficulties of seeing objects other than on the ground, and of hearing; and to overcome them it usually becomes necessary to direct the pilot and observer by signal (visual or wireless) from the ground, to assist them in finding the target which has been selected for attack.[1] Other serious handicaps to the observer in the air are the unstable platform for his gun and the difficulty of estimating the range to his target.

(*c*) The *heavier gun on the ground* acts in coöperation with the machine-gun in the air, and in substitution for it when weather conditions or other reasons prohibit the use of the aeroplane.

The gunnery problem is an extremely intricate one owing to the difficulties involved in range finding, the rates of change in angular velocity, the ease with which a target can change its height and course, and the fact that the target can only be engaged for a very limited space of time. The difficulties of the artilleryman originate from the time of flight of his projectile. On the other hand, he is not hampered as is the airman by the unstable platform and by the noise made by the engine.

(*d*) The *searchlight* has three rôles to fulfil in air defence. (1) It points out the selected target to the defending aeroplanes. At night the pilot is deaf and practically blind, and, unless he carries a searchlight in his machine, he must depend on those on the ground to show him where the target is moving. (2) It illuminates it for the artillery. The artilleryman on the ground is blind, and cannot use his sights unless his target is well illuminated so that he can see it. (3) It exerts a moral effect deterrent to the attack. It is necessary to read the personal narratives of night-flying pilots, and to listen to their conversations, to appreciate the great moral effect which the systematic and unhesitating use of searchlight beams has upon them when they are approaching their objectives on the ground. They know that once the searchlight succeeds in laying on them they become the target for every gun and aeroplane within reach — an experience to be avoided as far as possible.

There are peculiarities in a searchlight beam which handicap the detachment to a large degree; the principal one is the frequent inability of a man standing close to a projector to see a target in the beam from it. This is sometimes due to a general prevalence of a local mist which diffuses light in all directions in the neighbourhood of the projector, but it may also be due to the blinding effect of a secondary cone of light close to the base of the main searchlight beam, which prevents the man close to the projector from detecting the light reflected from the target. At distances, however, varying from 6 to 20 ft. to one side of the projector, the effect of this secondary cone of light is generally so slight as to cause no interference. Projectors have accordingly been provided with long control arms fitted with wheels or handles at the end, so that the man whose duty it is to manipulate the beam can do so with the minimum of outside assistance.

An aeroplane can, by "side slipping" or otherwise executing some unexpected manoeuvre, generally escape from a single illuminating searchlight, owing to the differences in the reflecting surfaces of an aeroplane when viewed from different angles. If, however, three beams manned by good detachments succeed in training on it, they can generally hold it whatever the gymnastics attempted by the target. On the other hand, if a target is illuminated by a comparatively large number of beams, say eight or ten, some of which must be at a considerable range from the target, there is a marked tendency for the latter beams to drop below the target altogether; although the detachments at those projectors are unaware of the fact that their beams are now useless, and may even interfere with the vision—and consequently the work—of detachments nearer the target.

An incident which took place during the German airship raid on London on the night of Sept. 2–3 1916, has been attributed to a reason of this nature. The Schütte-Lanz airship SL11, which was eventually burned that night and fell at Cuffley, was entering the area over London from a northerly direction. London itself was lying in what looked like a lake of mist, and the searchlights, which could hear the attack approaching over them, were seeking for it through the mist. Presently the airship was "picked up," and immediately from all quarters of the defences searchlights could be seen moving across to get on to it, until there may have been any number up to 20 beams shining in its direction.

The airship seemed to hesitate, and then swung round until she was steering north again. She was seen to empty one or more of her water ballast tanks and suddenly disappear. The searchlights lost her entirely for some minutes. Though, as is well known, she was eventually detected again and then held until she fell, there is little doubt that the searchlights were, in tho first portion of the engagement, hampering each other in their work owing to the exposure of too many beams.

In the same engagement a searchlight near Kenton was quite useless owing to a dense mist surrounding it and the gun station near by. The local reflexion of the light by the mist was so great that it prevented either gun or light detachment from seeing the target.

During the first years of the war discussions were often heard as to the advisability of throwing out searchlight beams, on the assumption that the target might not know where it was, and might therefore pass away without dropping any bombs; in other words that the exposure of searchlights invited the arrival of bombs. The answers to these suggestions are simple, viz. :—

(i.) The searchlights are there to be used, because guns and aeroplanes are blind without them. Guns and aeroplanes cannot defend efficiently without seeing their target.

(ii.) There is no justification for the assumption that the enemy has lost his way and does not know where he is.

During the spring of 1917 a general display of searchlights round London was arranged to test their efficiency as a moral deterrent on airship commanders. Every searchlight in the London area was given a prearranged arc through which the beam was to be moved slowly and regularly at a given signal, the movement to be continued indefinitely until the signal was cancelled or enemy aircraft became audible or visible to any of the detachments. The intention was to expose all the beams (some 120) simultaneously as soon as an attack was heading towards the London area, but whilst it was still sufficiently far away to give the airship commander plenty of time to think matters over, and remind him of the aeroplanes and guns which were waiting for him, and of the fate of some of his predecessors. On the two occasions when this scheme was put into force the attacks stopped short of the defended area and never came near it, though the German official communiqué announced on each occasion that they had dropped bombs on London.

A searchlight and its detachment are very vulnerable when within range of shell and machine-gun fire. On some occasions aircraft have occupied themselves in deliberately bombing searchlights, though the instances have been rare in England, and in no case was harm done either to the searchlights or to their personnel. On the other hand, in the areas where ground fighting was in progress, searchlights formed a vulnerable target for machine-gun fire from low-flying aeroplanes, though actual casualties were comparatively few.

The *sound locator* is an instrument which is intended to indicate the angle of elevation, and the bearing in azimuth, of aircraft audible but invisible from the ground.

Many types of sound locator were invented and tried by the various nations involved in the war, but none was eminently satisfactory. The fact of the matter was that but little was known of the vagaries of the paths of sound waves in the atmosphere. During and since the war, however, students have begun to appreciate and learn a few of its peculiarities, though at the present time knowledge of the subject is still little more than in its infancy. The pattern of sound locator most commonly used in the war was one with four trumpets, two for obtaining the direction in elevation and two for obtaining it in azimuth. In order to convey the information to the searchlight itself in as instantaneous a manner as possible, the locator was provided with a "ring sight," on the edge of which the searchlight beam was kept in contact by a "layer," who gave suitable directions to the men at the projector.

[1] By day the visual signal may be given by gunfire. By night it is more often made by the searchlight. For this purpose the Germans in Belgium erected large illuminated "arrows" composed of incandescent lamps in troughs of wood, designed to revolve on the roofs of concrete shelters.

A defect of this type was its inability to eliminate certain sounds which had nothing to do with aircraft, such as those from petrol tractors, motor-bicycles, etc., on the ground in the neighbourhood. The Germans in Belgium had to give up using their instrument at a searchlight near Bruges, because of the noise made by the frogs in the dykes all round it.

Another pattern of sound locator has been constructed in cliffs on the shore by cutting a concave surface in the face of the cliff, and providing an appliance for collecting the sound waves at their point of maximum concentration, in such a way as to indicate approximately the direction of the source of the sound. This pattern was used on the British coasts and warned observers of the approach of machines from Belgium when the latter were as far away as 15 to 20 miles. These locators also, however, were liable to error; and on one occasion a fleet of motor-boats caused an alarm which was only prevented from becoming public by the perspicacity of the local anti-aircraft commander.

The functions of the *observer post*, which may or may not be equipped with detector apparatus, are of great importance. The duty of the observers is to detect the passage of aircraft and report their movements to the authority controlling the air defences. On these reports depend the warnings to the civil and military authorities within the defended areas. Such duties demand considerable physical strength to bear the severe strain incurred by watching and waiting; and a high degree of refinement in hearing and eyesight, owing to the necessity of detecting and identifying aircraft at great distances. The speed of aircraft in the attack is the factor which determines the minimum distances of the posts from the objective, and those distances may involve the disadvantage of great isolation for many posts. The necessity of good and speedy means of communication between such posts and the controlling air defence authority to which they belong is obvious. However excellent an observer's training may be, a report based solely on what he has *heard* must be open to doubt, should it attempt identification of the class of the aircraft in question.

(*e*) The *aerial obstacle* consists of some form of wire impediment hung from balloons, and intended to be such a menace to a flying machine that it will either pass beside the obstacle or, more probably, fly at a higher level than the balloons supporting it.

The Italian authorities claimed extraordinary success with the contrivances used in their defences. The French authorities were not so optimistic over the type adopted by themselves, and there is no proven case of success with the pattern used in Great Britain.

The Germans at Bruges and Zeebrugge flew kites and balloons by wires of a very high tensile strength, and one Handley Page bombing machine with its crew was destroyed at Bruges by these means. The balloons were about 15 ft. in diameter, and were used when wind power was insufficient to raise a kite. The kites were of at least two patterns, but both were of the double box-kite type. The lower ends of the wires were wound on vehicles provided with gauges, oil baths, and lightning "earths." They were managed by a few small boys, pressed into the German service at the rate of a few francs a night. It was calculated that the wire provided an obstacle up to about 3,000 feet.

In Great Britain balloons moored by wire cables were arranged in lines, and at some distance below the balloons was a bridle connecting all the cables. From this bridle at equal intervals were suspended long thin wires of considerable tensile strength.[1]

Any arrangement of obstacles suspended from balloons must be particularly vulnerable, both from the shell fire of the defence and from any machine-gun fire brought to bear by the attack.

Many other forms of obstacles have been suggested from time to time, and perhaps one of the most ingenious was that of an aerial minefield. The inventor proposed to attach a small charge of explosive, sufficient to destroy an aeroplane wing, to a revolving vane by a length of fine cord. The charge was fitted with suitable percussion firing arrangements. The vane was attached for the purpose of delaying the fall of the explosive through the air. Charge, cord, and vane were neatly packed together so that considerable numbers could be carried in a box provided with a simple release. The procedure proposed was to send up a group of machines loaded with these "mines," on patrol well outside the defences, on any occasion when conditions were so favourable that a raid was probable. The "mines" were to be released across a broad belt through which the attack would probably pass, as soon as a signal was made from the ground that it had reached a suitable point on its course. The idea, however, was never carried into effect—probably owing to the danger involved to friendly machines,—but nevertheless it had possibilities which gave considerable promise, especially for use over the sea.

(*f*) *Bombproof and Splinterproof Protection.*—Local protection for personnel, animals and stores involves the provision of shelters proof against the bombs themselves and their splinters. A bomb with a stout and heavy point, and provided with a means to keep it revolving so that the point travels first, will, if launched from a great height, penetrate most practicable forms of shelter. A stout double roof of concrete with the sides sloping fairly steeply, and provided with a "sandwich" of some resilient material between the roofs, will probably give protection to what is beneath it, provided that the foundation supporting the roofs is a good one.

Many bombproof shelters made of concrete or big stones cemented together were constructed in France and Belgium by all belligerents, but they were generally of small capacity, and provided for particular detachments whose duties necessitated their remaining in the vicinity at all times. It is not, however, possible to provide such protection universally; in most cases all that can be done is to minimize the danger as far as is practicable, and to accept the fact that a direct hit on, or an explosion very close to, the person or animal will finish the matter as far as they are concerned. A little-known fact is that the open spaces in a big city like London may amount in total area to nearly ten times that on which houses are actually built, the chance that a bomb will fall on a house being therefore far less than is generally recognized.

The heaviest bombs used by both sides in the war made craters about 35 ft. in depth when dropped on ordinary soil and open ground. These bombs were fitted with fuses with a slight delay action. A light bomb with a very sensitive fuse was used by the Germans with deadly effect against men and animals. The crater made by it was practically negligible, all the fragments flying outwards and upwards. Protection against this type of bomb was afforded by low parapets of sandbags or sods, close to which troops could live; but horses were extremely difficult to protect against these so called "daisy cutters." In the open, protection during a bombing attack will generally be best found by lying down—in a depression if one be available.

In houses it is difficult to say which position is the safest; a bomb with a delay-action fuse will probably blow the whole house up from roof to cellar, while one with an instantaneous fuse will probably blow the roof in. On the whole, it would appear that the safest position of all is near the chimney breast in a room on the first floor, and below the level of the window sill. Such a spot may give protection from débris falling from the roof, and from splinters from a bomb bursting in the road outside, but is of course not likely to be of any use if the whole house is blown up.

Torpedo nets arranged in tiers about 10 ft. above each other may provide a certain amount of protection against small bombs fitted with instantaneous percussion fuses, but they are costly and difficult to erect.

Camouflage.—Concealment of the ground target may take more than one form. The landscape may be studied from the air, and the vulnerable points treated in such a way with painting and netting and so on, as to assimilate their appearance as far as possible with the surrounding country. Again, attempts may be made to hide an important point with smoke clouds during a raid, but unless the work is very carefully done the smoke may invite attention to the possible objective rather than conceal it. In any case it involves much careful organization, and may in the end prove very expensive. Lights and dummy buildings may be placed in exposed positions so as to form attractive targets for hostile bombing machines, at a safe distance but not *too* far from the point actually sought by the enemy. Thus a carefully arranged target of green, red, and white lights may successfully simulate and so protect an important railway junction.

Concealment of the principal leading-in marks has frequently been suggested; but success would only be likely with objects which were of small size, and therefore probably of comparatively small importance. For a big objective such as London, where there are such prominent guides in the nature of rivers, railroads and valleys, the expense of concealment would be enormous and the probability of success negligible. Moreover, the developments of wireless teleg-

[1] A curious incident occurred during an air-raid alarm in London during the war. To the astonishment of the detachments one complete series of balloons came down with unexpected suddenness, all being deflated by the rupture of their ripping panels. On examination, it was found that moisture had condensed on the ripping ropes and frozen there, until each cord was about as thick as a man's forearm. The weight had gradually increased on all with remarkable regularity until the ripping point was reached, when each balloon in the series was deflated almost simultaneously. There was a heavy mist that night, and the temperature at the ground level was above freezing-point.

raphy for directional and position-finding purposes would almost entirely neutralize any such work if it were attempted, on account of the size of the target. (See also CAMOUFLAGE.)

III. *Forms of Attack.*

The effects of bombing are moral and material. There is no doubt that the moral effect is far greater than the material—particularly in thickly populated districts where self-control, as a general rule, will be found lacking in the population to a greater degree than amongst armed forces in the field. No result decisive to a campaign has been brought about by a raid of any kind of itself alone. This fact will probably be true of aircraft bombing operations, provided that a country has taken suitable precautions in peace against the chance of an overwhelming attack at the very outbreak of war.

Written evidence was found during the war of the nervous apprehension reigning in a certain German town after the British special raiding force known as the "Independent Force, R.A.F.," had been operating for a comparatively short time. One of the inhabitants described a night of terror in which Allied aeroplanes had come in the early night and dropped their bombs and gone away. No sooner had the inhabitants come out of their shelters to go to bed than they were again summoned under cover, and the bomb dropping was repeated. Again they went to bed, and again they had to take cover—the performance continuing in this manner for some three or four hours. As a matter of fact one solitary Allied aeroplane paid a single visit to the town that night; the rest of the raid was purely imaginary, and the result of demoralization! Over another large town six long air raids took place during eight nights. One effect was that the clothing output from that district was temporarily reduced by 80%—a serious matter for the army, as a large proportion of the force was depending on the district for its clothing.

Bombing operations over disciplined forces in the field constitute on the whole a form of annoyance rather than a potential danger, provided that store and ammunition depôts are so designed as to be separated from each other, and subdivided within themselves, in such a way that a fire arising in one section may be properly isolated and prevented from spreading to its neighbours. Interference with movements of troops and stores by rail can be, and has been, caused by low-flying bombing machines.

Airship Attack.—Airships form targets of great size, and, if filled with inflammable gas—as were those of the Central Empires during the war—are objects of considerable danger to their crews. If and when a suitable non-inflammable gas is discovered which can be produced cheaply for commercial purposes, the airship will become a serious factor in air-defence considerations. It possesses greater endurance, radius of action, carrying capacity, accommodation, and facilities for observation than "heavier-than-air" machines. Meteorological conditions, however, will always militate more against the free use of airships than of aeroplanes, which possess higher powers of manoeuvre and performance.

During the war bombing operations by airships were not intentionally undertaken by the Germans over land targets by day, but ships at sea were frequently made the objects of such attention between dusk and dawn. Airships intending to attack land objectives in the British Is. used to leave their sheds by day, and make their landfall while still over the North Sea. There they would wait until it was dark enough to cross the coastline without prospect of serious interference, and make for their various objectives—as a rule more or less independently, but sometimes in pairs. The return journeys were made independently.

It has been held that at night it is hardly necessary to attack with more than one airship at a time, but there is no doubt whatever that simultaneous attacks by two or more airships on the same course add enormously to the difficulties of the defence.

The German raid on London during the night of Sept. 23–4 1916 affords a notable instance of airships setting out to attack in pairs, but failing to carry out their intention. L31 and L32 sailed on the task in company and reached Dungeness together. Thence L31, commanded by a bold and skilful pilot, set her course straight across London at high speed, and eventually won through. Her consort hesitated, and was lost.

L31 passed over Purley and Croydon, and dropped a very brilliant flare as she turned on a northerly course. This undoubtedly had the effect of distracting the ground defences from herself; for she was scarcely seen as she passed over the metropolis, and bombed it heavily without damage to herself. She reached home in safety.

L32 waited near Dungeness for about 40 minutes, and then flew north over Tunbridge Wells, instead of following L31. She avoided London, and dropped her bombs between Westerham and Ockenham. Near Billericay she was destroyed by fire.

Although there would appear to be much to commend such a course, "fleet" movements of airships in formation with the intention of bombing were not carried out by the Germans. However, it does not necessarily follow that a big attack of airships, either by themselves or convoyed by aeroplanes, will not form part of an extensive bombing operation in the future. The arrival of such an aerial flotilla over a capital city at the very outset of a war would do much to spread despondency and alarm; and if such a fleet succeeded in getting away unscathed, the attack might suffice to overturn all government in the state attacked.

Aeroplane and Seaplane Attack.—Bombing aeroplanes[1] by reason of their speed, difficulty of destruction from the ground, and comparative ease of handling in unfavourable weather, form the most serious factor in air attack.

The first aeroplane raid on London by day took place about noon on Nov. 28 1916. This was carried out by a two-seater machine carrying about half a dozen light bombs and flying at a high altitude. It was a courageous effort. Engine trouble brought the pilot to the ground on French territory, where he was captured with his observer. London was covered with clouds of dust which prevented all but a very few from ever seeing the machine. The success of the effort made it all the more surprising that it was never repeated; subsequent attacks in daylight were all made by machines flying together in considerable numbers and not singly. The most notable was that which took place on July 7 1917.

Before Sept. 1917, only a single attack on London was made by aeroplane by night. In that particular case (May 6–7 1917) the attack was made by a solitary machine which dropped most of its bombs on Hackney Marshes.

With these two exceptions, aeroplane and seaplane raids on England by day and night were limited practically to coastwise towns and shipping at anchor till the beginning of Sept. 1917, when aeroplane attacks on London by night were commenced seriously. These seem to have been made at first by machines in groups of three to five in number, but at the end of the same month, the groups appear generally to have split up on reaching the English coast, each machine taking its own line independently from that time onwards.

Machine-gun fire from low-flying aeroplanes and seaplanes will be encountered wherever targets present themselves: troops in action, in camp, or on the march, transport in movement, troops crowded on shipboard. But here again the principal effect will be moral rather than material.

Where ships lie at anchor in open roadsteads, or in harbours which offer a direct line of approach from the sea of moderate length, seaplanes will find targets vulnerable by the marine torpedo. The launching of the torpedo involves a close approach by the torpedo-carrying machine to the surface of the sea, and complete occupation for the crew of the machine. These facts render it necessary that such machines be escorted by one or more fighting machines, whose duty it is to protect them from attacks by air and if possible from fire from the shore and ships. Various methods of active protection suggest themselves—the destruction of the machine, harassing its aim, or deflecting the torpedo during the launching process.

Photography of the ground for intelligence purposes forms a highly important feature in aircraft work. With good lenses, photographic machines can do their work at immense heights, thus rendering their detection by the defence a matter of considerable difficulty.

Aeroplanes on hostile patrol constitute an armed guard whose duty it is to seek for enemy machines. Such patrols form targets for air defence formations when they are within range and the air forces proper are not at hand to take up their challenge.

Friendly machines acting as auxiliaries to ground operations—especially artillery machines observing the results of gun fire—are

[1] The paragraphs which follow are applicable also in the main to seaplanes. Nevertheless the typical differences between the two classes are not without importance from the point of view of the preparations against attack by one or the other. The principal difference is that seaplanes require no landing ground or special arrangements for landing on ships. They can also take in their fuel from ships. On the other hand they find difficulty in "taking off" in rough water. Their powers of manoeuvre are, however, comparatively limited. They come chiefly into the consideration of coastal air defence, owing to the necessity they are under of landing on water. But amphibious machines are certain developments of the near future, and wide canals such as that between Bruges and Zeebrugge have served as landing places and enabled seaplanes to operate from a point inland and safe from interference from the sea.

at a serious disadvantage if attacked by enemy aircraft, as their duties tie them to a comparatively small area at a fairly low height. To defend each of such machines by an aerial escort would absorb too great a number of fighting aircraft, and so the duty falls most frequently on the anti aircraft artillery and such machines as are allotted for air defence work—*provided that* the latter can be directed to the spot in sufficient time to provide the protection required.

IV. The Defence in General.

It will now be realized that air defence is required both in the actual theatre of active operations in the face of the enemy, and in areas far to the rear of the fighting line, so long as the enemy has machines capable of reaching those distant points and returning again from them. Bombing attacks may be met anywhere, *i.e.* both in the forward area of ground operations—the "Front"—and also in store depôts, bases, ports, and large cities far removed from them. Low-flying machines with bombs or machine-guns may be encountered far in rear of the "fighting line," but principally in or near it and over the communications immediately behind it; so that, as a broad general rule, the nearer the "line" the greater will be the proportion of low-flying targets, and *vice versa.* Torpedo-carrying machines will be met with over the sea; and photography machines anywhere between the "line" and points far in rear of it on the lines of communications.

In order to place defending aeroplanes in positions favourable for engaging their targets, it is necessary to obtain information of the attack in sufficient time. This leads to two great essentials in any scheme of air defence, namely:—(*a*) intelligence, and (*b*) communications.

(*a*) *Intelligence* can be treated under three headings:—(1) during peace, and before the beginning of an attack in war; (2) during an attack; (3) immediately after an attack.

Intelligence before the beginning of an attack includes information obtained during peace of all the resources of a possible enemy; his preparations and probable intentions; with the numbers, details and performances of his machines both civil and military. On such information will the whole scheme of air defence of a country and its forces in the field depend. In peace such information can be collected, compiled, and assimilated in a careful and comparatively slow manner. But directly a state of war arises, speed in the collection and transmission of that intelligence to those whom it most concerns, *i.e.* the executive in the air defence services, becomes the prominent factor. The authority responsible for the collection of that information has to add comparatively suddenly to his ordinary peace-time duties that of rapidly tracing the movements of both hostile and friendly aircraft, as by no other method can an officer check information sent to him by his observers. Only on the efficiency of the preparations made for the use of telephone, telegraph, and other signals can he hope to issue the warnings which will be required by the population to enable them to take cover during a raid. The state of war may even be heralded by the air attack itself, and there may only be a matter of a few hours for the transition from "intelligence duties during peace and before an attack" to "intelligence during an attack."

It will be best to consider a concrete example, which will show perhaps more than anything else the necessity for speed.

Take an imaginary city with an average radius of 12 m., with its centre situated 30 m. west of the sea. One night a ship 60 m. east of that city reports a number of aeroplanes as having been heard passing high overhead, going west at an estimated ground speed of 100 m. per hour. The message, which is probably sent "in clear," is picked up by some coastguard station, which sends it to the local senior naval officer and so to the military garrison commander near at hand. These officers, after digesting the report, and confirming it if possible, send it on through their respective headquarters to the central organ of the system. Thence it goes to the railways, to the police, and to air defence headquarters, who give the alarm to the railroad men, to the civil population, and to the squadrons, guns, and lights, etc., of the defences, respectively.

The defending squadrons will probably be situated from 15 to 20 m. from the centre of the city, *i.e.* about 40 to 45 m. from the source of the report. At the squadron aerodromes the pilots, who are waiting ready to start up the machines, "taxi" over the aerodrome, and then "take off" and begin to climb to predetermined heights, as the real height of the attack cannot be known at the moment.

A little time-table will show the time probably left to them to get up to, say, 10,000 feet.

	minutes
Time taken by attack to travel 40 to 45 m., say . .	27
Ship to shore	5
Coastguard to local H.Q.	2
Local H.Q. to main H.Q.	2
Main H.Q. to Air Defence H.Q.	2
Air Defence H.Q. to units	1
Starting up machines, "taxi-ing" and taking off .	5
Total (say)	17
Leaving the machines to get their heights in . .	10

A single report of this nature would suffice to send out an alarm far and wide, and turn the defence posts over a vast area into seething points of activity; whilst there might be nothing whatever to show that those machines were hostile, or that if hostile they were going to attack the city in question. The initial probability was that they were hostile; and as they happened to be going west at a point 70 odd miles east of the city, the time required to get the defending aeroplanes into position would leave no option but to assume that the attack was coming to that city. Yet the attack in this instance might easily turn aside as soon as the coastline was made, in order to proceed to some other objective; there was no certain indication beforehand of the real one, and there may never be.

The foregoing example shows that the observer system of a defensive organization for a big "vulnerable point" must extend to a radius of from 70 to 100 m. from the probable main objective of hostile attack by air, if the executive is to have sufficient time to get its defences into a state of readiness for action, and the civilian population and railways properly warned of the approaching danger.

As soon as the attack enters the area in which anti-aircraft posts exist, each of such posts within sight or earshot of the attack becomes a potential source of information. It remains then for the commander of the air defences to organize a system of speedy intelligence within his own command, which can be supplemented by reports collected from police and railways, which may or may not assist in checking the reports received from the defence posts themselves. This system continues its work until such time as the attack withdraws to a point outside its boundaries, when intelligence is again required from outside sources until it is certain that the engagement is over.

Directly after the attack it becomes of importance immediately to check the commander's ideas of the battle, to supplement them with local details of what actually happened, and to compile as complete an account as possible, showing:—Nature and numbers of aircraft employed on each side; routes followed by attack and defence; casualties to personnel and material; number and nature of bombs dropped; expenditure of ammunition; size, speed, and manoeuvres of enemy machines; new features of machines, if any; efficacy of communications; weather conditions, etc. This report is of high importance and may enable a commander, if it is compiled and issued rapidly, to dispose his forces afresh in sufficient time should features in the attack show this to be necessary.

In this connexion, it is important to note certain peculiarities of air-defence information. A report on the position of aircraft *in movement* is incorrect the instant after the observation is made, unless the time of the observation is given. The value of the report decreases with every moment that elapses after the observation. To be of value at all it must specify whether the aircraft was seen or only heard; if the former, whether friendly or hostile; and the time of the observation. To be of real value, it should contain data as to the direction of flight, the number and type of the machines and their height. One of the outstanding curiosities of the air raids over England was the remarkable inaccuracy of the reports rendered by eyewitnesses which were received at the various headquarters. To men who have been in the services the hypothesis that the man "on the spot" knows what is going on and therefore knows best what should be done, will be familiar. The history of anti-aircraft operations during the war abounds with instances showing the fallacy of that hypothesis.

During the aeroplane raid of June 1917, over Sheerness, Gravesend, Wrotham, and Folkestone, two independent reports were received of an airship approaching London in broad daylight from

a point between Gravesend and Wrotham. They were the only intimations of any airship being present. One of the reports came from an officer, and one from a searchlight detachment; all had been used to seeing airships at night and knew what they were like. They were closely questioned, and there is no doubt that they were mistaken, but none of them was ever shaken in his conviction that he had seen an airship.

The gun detachment at Hyde Park were threatened by an angry crowd one afternoon in June 1917, because they would not open fire on a British machine flying high overhead. An air raid was actually in progress over East Kent at the time.

Bombs were reported one night as dropping in places up and down the eastern portions of Lincolnshire and Yorkshire, but a duty officer sitting over a map in London could only trace the noises to echoes of a serious explosion which had taken place a short time before in Lancashire; so he assumed the responsibility of declining to give an alarm; he was right.

An airship was reported as visible and audible over the scene of the great Silvertown explosion in east London within a few minutes after the last explosion there had taken place; it was identified with a curious wisp of smoke which many spectators had noted in the glare of the flames. The sound of the engines was purely imaginary. Thin long clouds were frequently reported as airships on moonlight nights.

These few examples will show the unreliability of reports concerning aircraft, and bring into prominence the enormous responsibility resting on the shoulders of the "duty officer," who, sitting miles away from the scene in a closed room, has to decide whether an observer really has seen or heard what he has said he did.

In making observations on the movements of large cylindrical airships, a common cause of error is due to the lack of an appreciation of the effect of perspective. An airship travelling horizontally and straight away from an observer may give the impression of falling vertically, nose downwards. An obliquely approaching airship may appear to be gaining height, and *vice versa*, although travelling at a constant height. Further, the observer on the ground is unable to assist himself by comparison of the size of the machine with other objects, the sizes of which may be familiar, placed at gradually increasing distances from him, and between himself and the airship.

The vagaries of the path of sound emanating from aircraft have proved extraordinarily deceptive. An officer accustomed to living in a shelter on a roof in the heart of London was able, while inside the hut, to detect sounds of aircraft which were quite inaudible to him when he was outside it. Local slopes and wooded country lead to confusion in the intensity and direction of the source of sound.

During the raid of May 23–4 1917 on the London area, airships were reported independently as "almost overhead" by three experienced anti-aircraft detachments in the neighbourhood of Hoddesdon and Hatfield, though no airships came nearer than within 25 m. of them; the mistake was probably due to peculiar and dense cloud formations which lay over the London area at the time. During the same engagement, bombs dropped between Braintree and The Wash were reported as clearly audible from Putney Heath and south-west of it.

In a civilized country, warning of an approaching attack by air is required by both civil and military populations. Here again the organization must be based on "areas." It is not possible to decide beforehand the objective of attack by air, but it is possible to fix the degree of probability of attack on the different vulnerable points in any country. In each of such vulnerable points certain precautions are necessary, such as the evacuation of the workers from an explosive factory, the dowsing of bright lights, or the control of railway traffic. These precautionary measures take time to bring into force but it is nevertheless desirable to bring them into force only at the very last moment, in order not to delay output or cause unnecessary alarm and congestion. It becomes necessary therefore to keep a quick and careful record of the enemy aircraft movements, to divide up the country into "warning districts," and to provide a good system of distributing the warnings.

The movements of the attack are recorded by the "intelligence" system. The sizes of the warning districts depend on the speed with which the attack may move, as well as on the time required to bring the precautionary measures into force. The system of distributing the warnings will rest with those civil authorities who act as guardians of the public safety, who will probably use the civil telephone system.

Warnings and orders will normally be divided into: (a) preliminary warnings as to the approach to the area of an attack; (b) definite military orders as soon as the attack has entered the area; (c) messages cancelling (a) and (b).

As regards railways, special arrangements are necessary. Complete stoppage of railway traffic creates such disorganization that weeks may be taken to recover from it. Failure of train service causes the assembly of huge crowds of would-be passengers at railway stations, and so the formation of "vulnerable points" in which a single bomb would cause immense destruction of life. The dislocation of the traffic suspends the punctual delivery of goods, and upsets transport arrangements throughout the whole country traversed by the railway system, as well as in the ports to which it is connected. The control of the traffic therefore remains in the hands of the railway authorities, who are advised by the military authorities of the assistance the system may afford to hostile aircraft under certain circumstances. Both the railway and military authorities render each other mutual assistance in the interchange of information regarding the progress of an attack by air.

(*b*) *Communications.*—The rapidity with which aircraft move, and the uncertainty of their objectives, render necessary a very complete system of communications. Without such provision the intelligence gained cannot be collected or information and orders distributed in sufficient time to meet an attack before it arrives over its objective, or to enable precautionary measures for the public safety to be taken.

Signals may be sent by wire, wireless, and visual means. Means of communication are required between:—

Points on land, Ships on the sea, Machines in the air,	and	points on land. ships on the sea. machines in the air.

Signal by wire is only possible between stationary points, *i.e.* those on land or the shore and anchored vessels afloat. Visual signalling between machines in the air and points on the ground is limited chiefly by atmospheric conditions, but also by the necessity of concealing the position of machines in the air. As between points on the surface of the earth, intervening ground features as well as atmospheric conditions may interfere.

In order to minimize the inevitable congestion which arises where the same wire circuit is used for the dual purpose of collecting and distributing information, independent methods must be provided for the two processes wherever this can be arranged. As far as possible information should be collected by wire circuits, but after verification it may be distributed by any method available. Wireless is of value between machines in the air to enable formation commanders to communicate with each other and with the machines under them. Wireless signal facilities are also required to enable machines to check their navigation reckonings, and to assist them in locating landing grounds, particularly when fog or cloud prevail. For the communication of intelligence before the latter has been thoroughly investigated its use is a source of danger, owing to the ease with which wireless messages can be "picked up" and to the large proportion of inaccuracies to be found in messages concerning aircraft.

These broad principles apply to all "back" areas; but in "forward" areas, where shell fire renders the maintenance of wire circuits almost impossible, resort to wireless alone may be necessary, if the passage of aircraft intelligence is essential in the area affected. That the highest standard of accuracy and rapidity is required to make the service of communication efficient for crises in which minutes are precious goes without saying.

V. *The Application of the Various Instruments of Defence.**

In order always to be as economical as possible, air defences must not be disposed too far from the area they are intended to defend. As the attack can come from any direction, they must be disposed all round that area. To dispose ground defences along the boundary of a state with aeroplanes on patrol on either side of them, in order to keep the invader out of the state

at the outset, is to be "strong everywhere," and consequently "strong nowhere." Such a policy involves dispersion of available strength over unimportant localities, reduction of control, loss of cohesion in effort, extravagance, and the achievement of a minimum of efficiency. The close defence of the localities which are important to the state is the only sound policy.

For the defence to be effective, the attack must be met and defeated at the right height and outside the line from which it can achieve its object. Such at least must be the aim of the defence, however difficult it may be of achievement. That is to say, the defence must be outside the objective of the attack. This necessity plunges the matter at once into difficulties with what is known in the army as the "chain of command." An army works by definite boundaries shown by real or imaginary lines on the ground. The air knows no boundaries. It follows, therefore, that those units of air defence formations which are tied to the ground must be sited and organized for purposes of command with no regard to those imaginary territorial boundaries necessary to the ordinary army of the ground, and solely with regard to the whole area in which the vulnerable point or points are situated.

In one respect the sea has an important bearing on the nature of aeroplane attacks. The risk of being shot down on the return journey while still over water, with little or no hope of rescue, tends to make a circumspect pilot fly high over his objective, even if this be some distance inland, as he must evade detection till he has gained such a start over the pursuers as will enable him to pass the sea in safety even with a damaged engine. This was apparently the policy of the Germans during the raids on London in Sept. 1917. Whether, in any given case, the pilot will thus sacrifice some of the effectiveness of his attack in order to give himself better chances of a safe return, will depend on his personal character, the traditions of his corps and the free hand or limiting instructions that he receives from his superiors. From the point of view of the defence this has its drawbacks. It is difficult to decide *a priori*, or even during the progress of the attack itself, as to the probable height of the enemy when the basis of the decision is practically conjecture. Another effect of the seacoast on anti-aircraft defences may be to limit them in area. The defences must extend over an area outside the vulnerable point; but, in cases of ports on the open sea, that area is limited to the ranges of gun and searchlight on the edge which borders on the sea.

Some typical instances of the use of the various instruments of defence may now be considered. The defence has to provide against attacks both by day and by night. By day the instruments of defence and their adjuncts are: the machine-gun in the air, the heavy gun on the ground, the sound locator, and the observer post. By night the machine-gun in the air must be manned by a crew specially trained in night fighting, and in addition there is the searchlight. By day and by night the object of the defences is to break up the enemy attack and destroy it in detail. By day the massed attack must be broken up by gunfire before the aeroplanes on the defensive are launched against it; this entails guns outside the defensive aeroplane patrols, which again are outside the vulnerable point. Then in support of the aeroplanes (*i.e.* in rear of them) more guns again are required to repel such of the attackers as succeed in penetrating the aeroplane patrol area. And lastly, throughout the area of the vulnerable point itself, provision must be made for attacking by gunfire any hostile machine which may succeed in penetrating so far.

The attack will probably be audible and visible throughout the greater part of its course. In certain conditions of thick cloud or haze it may be invisible from the ground, but this fact, though increasing the difficulties, does not alter the disposition of the defences.

By night the attack is broken up in an entirely different manner. Both attacking and defending machines being in darkness, the attack is, as it were, reconnoitred by the searchlight, and the targets selected by the latter are isolated for engagement by the apparently simple process of keeping them illuminated. Unless the searchlights succeed in their object, the attack is invisible.

It is not possible as a rule to illuminate several targets in a searchlight beam simultaneously, although during the war as many as five have been held in the beam simultaneously for a few minutes; nor is it likely that any method of illuminating a formation of, say, 22 machines simultaneously, for any length of time, would be practicable. The outer ring of guns, therefore, would normally remain inactive by night unless the absence of a defending aeroplane gives an opportunity for a gun to engage an enemy target.

By day and by night the aeroplane in defence can only move a certain maximum distance on patrol without running the risk of allowing an attack to slip past in rear of it; the aeroplane also requires a certain minimum distance on one side or other of its patrol line in which to manoeuvre and bring its enemy to battle. Suppose for the purposes of illustration these measurements be taken at 15 and 10 m. respectively. The aeroplane patrol area, and the battle and pursuit area, must be kept as clear as possible of gunfire areas and areas containing vulnerable points of any size.

The width of the gunfire area will depend on the probable height at which the attack is delivered. Assuming that the latter is 10,000 ft. and that the gun can command a horizontal range of three miles at that height, the belts of gunfire may be taken at six miles in width. Observer posts must be between 70 to 100 m. away, as has been shown, in order to gain time for the defences to get into position, if they are to meet the attack as it comes in and not bring it to account merely as it is returning home.

In the case of a vulnerable area represented by a circle of a radius of 5 m., the area immediately outside that will be a belt for gunfire from 3 to 4 m. in width; the next a belt of 10 m. for the aeroplane battle and pursuit area; then one of 6 m. for the outer gunfire area; and a final belt from 45 to 75 m. wide covered with a network of observer posts, each of which can be from 10 to 15 m. from each other. This arrangement provides for the problem of defence by day.

By night it is necessary to consider the disposition of the searchlights, and it will have been seen that one of their functions is to indicate the approximate position of attacking aircraft. To be of any value they must be able to do this throughout the vulnerable area, the adjacent gunfire area, the battle and patrol area, and for a sufficient distance outside the latter (say 4 to 5 m.) to enable the aeroplanes patrolling in defence to move into position to meet the attack. This gives the total area through which searchlights must be disposed, the projectors being at the angles of triangles whose sides measure approximately 2,500 to 3,000 yards. Owing to accidents on the ground, trees, houses, railway stations and the like, the actual distribution of searchlights throughout the area often appears to be indiscriminate; it is inadvisable as a rule to place a searchlight nearer than from 200 to 500 yd. from a gun. Again, by night, the difficulties of determining the height of the attack are so great, that it becomes necessary to dispose the aeroplanes in defence at different heights. Assuming this difference to be 1,000 ft., and that there are five machines one above the other, with the lowest at about 8,000 ft., the highest will be at 13,000 feet. The degree of endurance to be expected of a pilot flying on patrol at night may not exceed a tour of two hours in the air.

These data, combined with a knowledge of the average lengths of the summer and winter nights, will be sufficient to give some indication of the minimum numbers of machines and pilots required in the problem of night defence. The number by day is also affected by the probable frequency and size of the attacks.

It will now be easy to realize the enormous scale of defences required if any appreciable degree of efficiency is to be attained.

A simple diagram will illustrate this general disposition of defences.

Few "vulnerable points" are as symmetrical as those indicated in these diagrams, but the principle illustrated can be applied to areas of almost any shape.

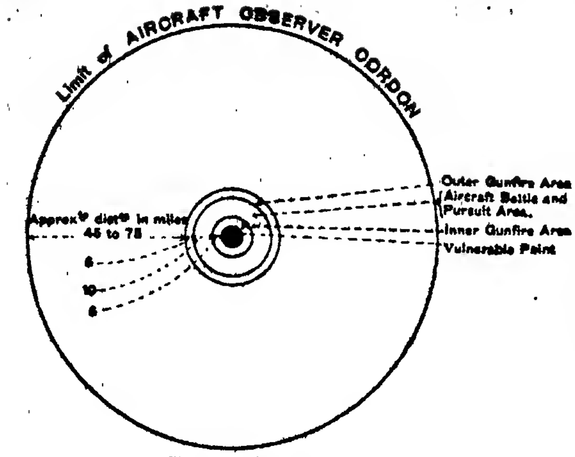

FIG. 1—Day.

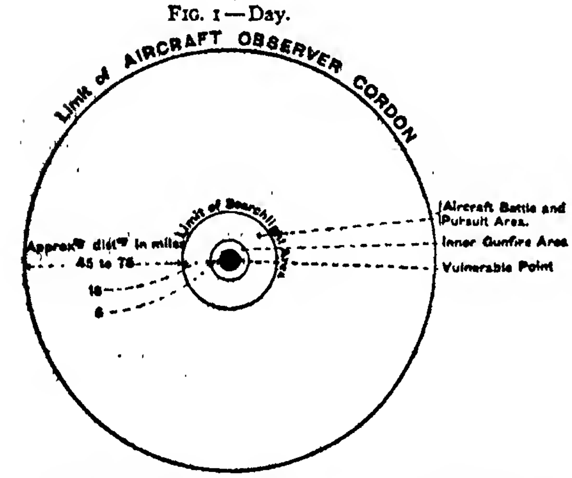

FIG. 2—Night.

By taking the maps of any state and applying these principles to the important towns, it will readily be seen that the matter is in reality considerably more complicated than it at first appears. For example, the defence area for Birmingham cannot be separated from that for Coventry. The defence of London is closely associated with that of Woolwich, and both of these are intimately linked with the defences of Gravesend and of Chatham; so that it eventually becomes necessary to look upon the whole district south of a line between the Wash and the Bristol Channel as a single area to be provided with defences under one command. Therefore this whole area will, for purposes of air defence, have an organization independent of all those ordinary commands and military formations whose activities are limited by conventional lines on a map.

The same line of reasoning applies to forces in the field with their "forward" areas, lines of communication, and bases; and necessitates the problem of air defence being considered with reference to the whole area of active operations, and not merely to that of all the independent vulnerable points within it.

The principle illustrated in the diagram will be found applicable to most cases, provided that consideration is given to the relative urgency of demands for gun and aeroplane defence combined, and of aeroplane defence alone. For the civil population, whilst applauding the courage and success of the airman, is ever apt to mingle with its praise a demand for a gun. A gun is tangible and comforting; it can be seen and heard; and so it produces on the population a moral effect which may be more than counterbalanced by the interference it may cause to the defending airmen.

An instance, already alluded to, in which the principle requires modification, is that of coastal towns and harbours, few of which can be situated geographically so as to admit of the all-round disposition of defence illustrated. Here the sea intervenes to cut off observer posts, searchlights, and guns, in addition to restricting the area of manoeuvre for the defending aeroplanes by night. This inroad into the defences offers the enemy an avenue of approach, and necessitates considerable strengthening of the batteries within range of and covering the sea in the neighbourhood. A certain amount of defence may be afforded from vessels afloat, but reliance cannot be placed on them for anything more than a temporary assistance, as they may only be present for uncertain periods.

All that can be done is to increase the intensity of the gunfire belt to seaward, and to provide aircraft detector posts and instruments with a directional value in azimuth rather than vertically. The latter serve as a partial substitute for the observer cordon by giving somewhat distant warning of the approach of aircraft.

The defence of towns and ports separated from enemy territory by sea alone thus requires maintenance in a state of instant readiness for action, and so calls for a greater complement of personnel than would be the case in defences situated inland.

The areas on either side of the dividing "line" between opposing forces in the field, up to a distance of some miles from the dividing line, were generally described during the World War as "forward" areas. The areas behind the forward areas were usually termed "back" areas; the latter term, however, was not generally taken to refer to places outside the "theatre of war," though from the point of view of aircraft action it was just as applicable.

In "forward" areas vulnerable points in the nature of men, guns, animals, and ammunition stores are numerous, but as a rule well distributed. In "back" areas they all tend to greater concentration. Protection is therefore more easily afforded in the former than in the latter, and so the better targets for bombing machines will be found as a rule in "back" areas.

The nearer the "line" the more intense will become the fire of hostile ground artillery; this precludes the free use of searchlights nearer than about 5,000 yd. from the "line," and necessitates the distribution of anti-aircraft artillery in smaller fire units than is possible at a greater range from the enemy.

Targets will be far more numerous in the forward area than in rear of it, throwing much more work on the anti-aircraft artillery situated near the line.

Applying the principle, as illustrated in the figures, to the problem in the field, a distortion of the diagram results, as in the cases of coastal towns. The outer ring of guns (fig. 1) is formed by the guns "in the line" and such as can be spared to protect the flanks and rear of the force. Within that ring, guns will be concentrated closely around vulnerable points such as munition dumps, hospitals, etc., whilst the defending aeroplane will patrol in the space which may be available between. The maintenance of communication between the forward guns in the shell area becomes a matter of great difficulty and may require provision of special apparatus.

By night the guns "in the line" must rest as far as possible, and employ themselves with observation duties. Searchlights in the aeroplane battle and pursuit area nearest the "line" must perforce be curtailed, and the aeroplane patrol lines withdrawn to points which will admit of sufficient searchlights operating between them and the attack.

VI. Some Possibilities of the Future.

Some limit to the speed of aircraft and the height at which they can fly must be assumed, and, as far as the possibilities can at present be imagined, heights up to 30,000 ft. and speeds of 200 m. per hour, together with powers of long endurance in the air, may come within the range of practicability during the next 20 years or so. A successful development of the helicopter would bring about a great change in the power of manoeuvre of aircraft, and enormously increase the difficulties of the defence. Detection of approaching aircraft will be rendered difficult by the silencing of the machinery; their destruction by fire will be hampered by the introduction of metal protection. Wireless aids to navigation will decrease the difficulties of the pilot in thick weather, improvements in the landing power and stability of machines will increase their immunity from storms; and all these conditions will call for a greater state of readiness in the defence. On the other hand, improvements in artillery will be necessary, and will follow as a natural consequence. Inventions for the detection of the locus of the source of sound will facilitate the accuracy of searchlight work. These factors, in their turn, will impose greater caution on the attack and give greater confidence to pilots patrolling in defence. Aeroplanes now used in defence will in the course of years become less localized in their work, and will develop a tendency to operate more and more like battle-fleets at sea. Such aerial fleets operating from their bases will be likely to carry their own armaments and searchlights, and to be accompanied by what we may call their "destroyer flights," which will assist them to seek out and find the enemy themselves.

The improvements which will produce this tendency will only mature gradually, and danger will lie in the endeavour of the ground or air services to assume entire responsibility for defence against air raids before being in a position to do so. There must be a long transition period during which coöperation between air and ground units must be the strongest link in the chain of

defence. Only in proportion as the air services become of a more stabilized nature, and anti-aircraft artillery improves, will the need for close coöperation diminish; it will never entirely disappear. The inability of the British navy to prevent short raids on the East Coast towns of Great Britain during the World War must not be forgotten; in like case, no country will ever be able to make good a defence against aerial raiding attack by aircraft alone. Consequently a nation must guard against exposure in the transition period to dangers which the air services or ground services of themselves alone cannot avert. Local ground defences will always be a necessity; and reliance on them will become greater owing to the many and devious paths of approach open to the enemy taken in conjunction with the reluctance of a nation to expend the huge sums necessary to provide aircraft to watch them all.

Every disease produces its own remedy; and in the end only the highest degree of excellence attainable by the arms of defence on the ground, acting independently of the units in the air, will procure the maximum of immunity for vulnerable points.

(M. St. L. S.)

AIRD, SIR JOHN, 1st. Bart (1833–1911), British engineer, was born in London Dec. 3 1833, the only child of John Aird, contractor for gas and water plant. He joined his father's business at 18, and was entrusted with the removal of the Crystal Palace buildings from Hyde Park and their reërection at Sydenham. He took part in many enterprises at home and abroad, such as the Hampton and Staines reservoirs, the waterworks of Amsterdam, Copenhagen, Moscow, Bahia, Pará, Calcutta, Simla and Berlin, and later (in the joint firm of Lucas & Aird, afterwards John Aird & Co.) the St. John's Wood railway, the Hull & Barnsley railway and docks, the W. Highland railway and the great Assuan dam across the Nile. He represented N. Paddington in Parliament as a Unionist from 1887 to 1905, and was its first mayor in 1900. In 1901 he was created a baronet. He made a fine collection of pictures by British painters, the illustrated catalogue to which was printed in 1884. He died at Beaconsfield, Bucks., Jan. 6 1911.

AIR FORCES: *see* FLYING CORPS.

AIR RAIDS.—Air-raiding by airships, and still more by aeroplanes, was carried out during the World War in most of its geographical areas. German bombers were particularly active in France, and many towns near the Rhine suffered severely in later times from the aeroplanes of the British Independent Air Force. But nowhere can the history of the continual see-saw of success between raiding and air defence during the war be studied better than in the German raids carried out over England in general and against London in particular. Their story during 1914–5, 1916, 1917 and 1918 will here be narrated.

1914–5.—Directly Great Britain came into the war, the German High Command began to encourage their public with prophecies of the havoc the Zeppelins were about to work in England. Disillusionment came quickly. The experience of some of the smaller airships, attempting to work by day over Belgium and Lorraine, was by no means encouraging. Three were destroyed at once, and it became evident that for airships to fly low in daylight over enemy territory was to invite certain disaster. Hence it was that, although reconnaissances over the North Sea towards England were begun by airships, the first actual attacks were made by aeroplanes.

In Dec. 1914 a couple of bombs were dropped in the sea off Dover, and three days later, on Dec. 24, the first German projectile hit English soil. A small bomb fell near the Castle at Dover and broke some glass. Both these aeroplane attacks were in the nature of a surprise, and the defences, such as they were in those days, could take no action. On the following day a seaplane dropped a few bombs at Sheerness, without effect. This time both the ground and aerial defences took action; but British aeroplanes came in for most of the anti-aircraft fire from the ground. A few half-hearted attacks by aeroplanes and seaplanes made during 1915 were ineffective, except that two women were killed at Margate in September.

The barren honours of the first attacks having fallen to the aeroplane, it was left to the lighter-than-air machines to cause the first serious damage and loss. In the evening of Jan. 19 1915, two naval airships approached the coast of the eastern counties between Yarmouth and Cromer. They separated and dropped bombs on both towns. One of the raiders went out to sea again at once; the other, handled with greater boldness, proceeded to King's Lynn, dropping bombs as it went. Four people were killed, including two women, and the material damage was estimated at £7,000 or £8,000.

On April 14 the redoubtable Mathy, boldest and ablest of all German air commanders, began his activities over England. Commanding *L9*, a new and improved type of naval airship, he made a considerable tour over the North. On this occasion he was not particularly successful, most of the bombs falling harmlessly in open country. At Walsall, however, he succeeded in singeing the hair of a woman who was washing a little girl by the fireside. The following night L9 returned, accompanied by two other ships, and caused some damage in Suffolk. The next four raids were on a similar scale. Bury St. Edmunds was bombed in moonlight from a height of some 3,000 ft., the airship trusting to patches of fog to escape. Southend, always a favourite "fortress" for attack, suffered twice, three people being killed. On May 17 Capt. Linnarz, very active about this time in command of one of the military airships, while over Ramsgate descried the lights of London, more than 50 miles away, for the first time; but his orders forbade him to go inland, and this most tempting of targets had to be left for another occasion.

The opportunity soon came. On the night of May 31 1915 Linnarz succeeded in bringing his ship over the metropolis, in reply, so the Germans alleged, for a bombardment of Ludwigshafen. This raid was carried out in full moonlight, a fact that shows how much there was to learn at the time in the art of air defence. The great size of the thickly populated area of London makes it an ideal target for promiscuous bombing. There was on this night only one raider, armed with an inefficient type of bomb, but 41 people were killed or injured, and more than £18,000 worth of damage was caused. The bombs all hit the eastern part of London north of the river; one of them fell into a tank at John Walker's whisky distillery in Whitechapel. Fortunately the tank contained water only.

Further raids in Yorkshire and Kent on June 4 had little result, but two nights later Mathy again attacked the north, this time doing much more harm than before. He found Hull, came down low over it, and killed 24 people, besides wrecking some 40 houses. The people of Hull, exasperated by this experience, broke out and smashed up a number of shops supposed to be German, but a better revenge was in store, for another airship, LZ37, that attempted to raid on the same night was totally destroyed by Lt. Warneford while it was returning home near Ghent, and fell in flames, one member only of the crew escaping alive. The first serious military damage in England was done by a single ship that raided the north on June 15. Some works in Yarrow were hit, 18 men killed and a number injured.

In commenting on the first raid on London on May 31, the Press had to come to the conclusion that it was in the nature of a trial trip, and this view was justified by the series of nine organized raids that took place in the latter part of 1915. The series opened inauspiciously for the Germans, a Zeppelin engaged in bombing Dover being hit by a new 3-in. gun that had just been mounted there. She struggled across the Channel, losing gas rapidly, and fell into the sea near Ostend, where she was finished off by bombing aeroplanes.

London was reached on four nights during this period. Twice the results attained serious proportions. On Sept. 8 Mathy, now in command of L13, an improved type of Zeppelin, came in over the Wash, steered straight on London and bombed the City deliberately and with considerable success. Fires broke out in many places, and the damage done amounted to more than £500,-000. Mathy also took part in the raid of Oct. 13, when his ship bombed Woolwich. On this occasion the casualties were 71 killed and 128 wounded. These losses were severe enough, but they were nothing to what the German public was led to

believe; it was during this time that many of the airship commanders began lying freely, and "bombing" places they never went near.

The anti-aircraft defences had not yet been able to take the measure of the attack, and the good shooting of the Dover gun, mentioned above, was the solitary success that can be claimed for the ground defences up to the end of 1915. A few aeroplanes had been allotted to home defence, but they were quite unsuited for their task on account of their poor climbing power and their inefficient armament. The pilots, also, had but little training, and night landing grounds were few and very far between, so that ascents during 1915 for the attack of airships led in nearly all cases to fatal or serious injury to British pilots, and the attempt was looked on as a forlorn hope.

1916.—The defences could do no better in the early raids of 1916. Nine Zeppelins manoeuvred over the Midlands on the last night of January, one getting nearly to Shrewsbury. Seventy people were killed. Out of 16 British aeroplanes that went up in pursuit, 8 crashed on landing. A month later 2 airships were able to sit over Hull and bomb it from a low height, without any interference from the defence. From this time, however, defence took an upward turn; the change for the better began to show about the beginning of April 1916 during the very next series of raids. L15, one of the five ships that attacked on March 31 1916, in attempting to reach Woolwich, was hit by the gun at Purfleet; it was then attacked in the air by Lt. Brandon, eventually falling into the sea off the coast of Essex. Mathy's ship was hit by a shell on the same night, but he managed to struggle home.

A wholesome dread of defended areas now began to be observable in the German tactics. For instance, during the last raid of this April series, Hull was undoubtedly saved from further bombing by some new guns just installed there.

Fifteen airship flights were made over England and Scotland during this April period. Edinburgh was bombed with little effect; nothing came over London, although some bombs were dropped as near as Waltham Abbey. British losses were 84 killed during the series.

Further raids at the end of April were organized in conjunction with the naval bombardment of Lowestoft and Yarmouth, the whole operation being timed to coincide with the rebellion in Ireland. A large number of airships took part, but the result was small. London was saved from bombing by its defences on April 25. One Zeppelin ran out of petrol and was eventually destroyed on the coast of Norway.

The shortness of the summer nights prevented further raids until the end of July, when four attacks were delivered, indicating an ever-increasing respect for the defences. Twenty flights over England produced infinitesimal results, if we except the loss, at Hull, of 10 lives. An abortive raid on Harwich was followed on Aug. 24 by an attack on London by Mathy, now in command of L31, a new Super-Zeppelin; he showed his usual dash, skilfully avoiding the defences by making use of clouds. He threw several 240-lb. bombs, the largest then known; they caused a few casualties and considerable damage in southeast London and round about Blackheath. The raid of Sept. 2 was carried out by 14 ships and was a determined attempt on London. The metropolis was undoubtedly saved by the brilliant action of Lt. Robinson of the R.F.C., who did not hesitate to attack the military airship SL11, although she was under very heavy gunfire at the time. As he fired his third drum of ammunition into her, she burst into flames and fell, a burning mass, near Cuffley. The sight of this disaster was too much for the other commanders, who turned tail and made the best of their way home. British casualties included only three killed.

The next series of raids, begun on Sept. 23 1916, was of great importance. The German command were not deterred by previous losses from again risking their best airships and pilots in the attack of London. They conceived, not unreasonably, that if London could be terrorized, they might touch the *moral* of the British Government, and so produce an appreciable effect on the conduct of the war. On Sept. 23 1916 the weather conditions over the North Sea were favourable for raiding. Eleven airships left German sheds, nine crossed the British coasts, and the main attack was directed on London by three of the newest Super-Zeppelins, coming in from the east and south-east.

Having crossed the Essex coast shortly before 11 P.M., L33 was over east London ten minutes after midnight. Here she dropped twenty bombs. London, however, was no longer the helpless mass of former days. The searchlights continually lit up the hull of the airship, which was at 12,000 ft.; she was badly holed by the guns, one of her engines was damaged, and she began to lose gas and fly clumsily. To add to her miseries, Brandon of the R.F.C. now brought his machine close up to her. For twenty minutes he stuck to her, pumping bullets into the fabric. As she laboured back towards the North Sea, the crew threw out everything they could lay their hands on, including the machine-guns. Her commander crossed the coast at Mersea Island, going out due east. But the certainty that his ship would fall into the sea was too much for him; he turned her about and came to earth three miles inland at Wigborough, near Colchester. A specimen of the latest type of Zeppelin thus fell nearly intact into British hands.

Mathy meanwhile brought his ship L31 in company with L32 up the English Channel and, turning in over the Kent coast, made straight for south London. On the way he dropped a few trial bombs to test his sighting. Approaching the defences, he handled his ship with great skill and succeeded in blinding some of the British searchlights, that were picking him up, by throwing out powerful illuminating flares. He passed straight over the centre of London, crossing the Thames near London Bridge. South London and the extreme north suffered severely; but, for some reason, Mathy threw no bombs in the central districts, where he could have done most damage. He got clear away this time, and went out to sea by Yarmouth. The handling of the companion ship, L32, was not of nearly so bold a character. Her commander began to hesitate as soon as he had crossed the coast of Kent, and he spent an hour circling about Romney Marshes. When eventually he started N. for London his courage again failed, and he kept edging off to the E. so as to avoid the central defences. His caution could not save him. As he crossed the Thames near Dartford he was picked up by lights and attacked by guns. In order to rise he dropped most of his bombs in open country. His efforts were of no avail. Brandon, who was still in the air, describes the ill-fated ship as being "hosed with a stream of fire." This was the attack delivered by Lt. Sowrey, also of the R.F.C., who succeeded in setting the ship on fire in several places; she fell in a mass of flames at Billericay, in Essex. The British casualties on this night were 41 killed, including one aeroplane pilot. The enemy would hardly see in this an adequate return for the loss of two new airships with their crews.

On the night of Sept. 25 four ships raided the north, bombing Sheffield, where 29 people were killed, and narrowly missed Manchester. Two other ships, whose commanders had already become noted for their caution, came up to the Norfolk coast but would not cross it. Mathy, on this occasion, took his ship on an entirely new line. Passing through the Straits of Dover, he flew up the Channel as far as the Isle of Wight, where he turned N. and went straight over Portsmouth. He dropped no bombs on the fortress or dockyard. Near Hastings he went to sea again on what was to be his last voyage to Germany.

Yet another serious attempt to bomb London was made on the night of Oct. 1. Eleven ships started from Germany. Three of them made an innocuous tour over Lincolnshire. Mathy in L31 came in over Lowestoft about 8 P.M. and as usual steered an excellent course on London. Soon after passing Chelmsford, however, he found that the outer defences on that side of the capital were ready for him. A searchlight picked him up. He therefore turned and steered N.E. for some 15 minutes. Turning again he flew S.W., in order to get into position for his favourite dash down wind over the city. After drifting a few moments towards Ware, he set his engines going and started for north London at full speed. Suddenly a heavy gunfire was opened on him, and he decided to abandon his attempt. He threw out all his bombs, at the same moment executing a Very

remarkable right-hand turn that must nearly have broken the back of his ship. The pursuing aeroplanes were close upon him. He did all that was humanly possible to save his ship. He tried flying towards the W. on a zigzag course, rising and falling, in order to escape from the lights that continually held him, and from pilots who would not be shaken off. An airship once caught in such toils has little chance of escape. The end came quickly. Lt. Tempest came up to the ship at 12,700 ft. and brought her down in flames at Potter's Bar. Thus perished Mathy, the bravest and most skilful, as well as the most successful, of all the German commanders. The fall of Mathy's ship had an immediate effect on three other raiders, who all made a sharp turn for home the moment they saw it. After his victory, Tempest crashed on landing at North Weald Bassett, but was unhurt. During the whole of this great raid the only British loss was one man killed. The defence of London had now definitely got the better of the lighter-than-air attack; after this period no German airship ever flew intentionally over the metropolis.

Deterred by the victory of the London defences, the German command turned their attention to the north for the final effort of 1916. They met with no better success. Of the ten ships that left Germany in the course of Nov. 27, eight came over land. One was destroyed on the coast near Hartlepool before midnight by Pyott of the R.F.C. She fell blazing into the sea. Although the pilot dived away at once to avoid the flaming mass, his face was scorched by the heat as she fell.

Another raider, L21, after a remarkable journey right across England to Cheshire, was caught in the early morning just as it was growing light, when she was leaving the coast at Yarmouth. Three British naval aeroplanes came up with her. Cadbury attacked first, but exhausted all his ammunition; his experience was destined to be useful to him on a subsequent occasion. Another pilot then tried, but his gun was frozen up and jammed. The third pilot, Pulling, then went right in to within 60 ft. of the ship, under a heavy fire from her machine-guns, and succeeded in setting her alight. It is a curious fact that machine-gun fire was kept up from the gondolas for a considerable time after the hull had begun to burn. She fell into the sea from 8,000 ft. and sank at once.

Other raiders, seeing the disaster near Hartlepool, turned for home again without attacking. Those who came in over land found that the ground defences were very different from what they had expected. The guns and lights were successful in keeping the raiders off their targets. The British losses were one man and three women killed.

During 1916 eighteen raids were made on England by aeroplanes and seaplanes. They were nearly all of the "tip and run" variety, and consisted in coming over the coastline, dropping a few bombs haphazard and getting away as soon as possible. The attacks were delivered with no apparent military purpose, and they had practically no effect.

The first aeroplane attack on London was made on Nov. 28 1916 by a single machine; the weather was misty and the first intimation was the fall of six small bombs between Brompton Road and Victoria station. The raiding machine had an engine failure on the return journey and was forced to land within the Allied lines near Boulogne. Lt. Ilges, the pilot, had set out to take photographs and bomb the Admiralty.

Before the beginning of 1917 the defences had quite definitely beaten the attack, so far as concerned operations by airships against London. Over the rest of England the airship commanders were tending more and more to avoid defended places, consequently the damage they could do was limited to objectives of secondary importance. It is a significant fact that of the nine Zeppelin commanders who attacked in Jan. 1916 three had been killed and two others taken prisoner, their five ships being destroyed by the action of the defences, before the end of the year.

1917.—The three airship raids of the first half of 1917, carried out under the conditions indicated above, produced little result other than the loss of two of the raiders, one being shot down while on the way home by a French gun near Compiègne, the other being destroyed by one of the defending aeroplanes near Harwich. On the night of May 6–7 a single German aeroplane appeared over the East End of London, and dropped a few small bombs. The attack, in itself, was unimportant, but it afforded an indication of what might come later.

Before the end of 1916 it had become evident to the German command that, if effective bombing was to be kept up on targets that were worth attacking, it would be necessary to try new methods. Early in 1917, therefore, they began equipping a squadron with special machines suitable for bombing England systematically. This formation, known as the 3rd Bombing Squadron, was distributed in aerodromes about Ghent, roughly 170 m. from London. The new machines, of the Gotha type, were capable of flying with a full load of bombs at 12,000 ft. and over. They carried a crew of three, pilot and two machine gunners. In May 1917 the squadron was ready for action, and as soon as the weather became favourable the attacks were to begin. The raids, with the exception of two minor attacks on Harwich, were aimed at London, but on the first two occasions unsuitable weather caused a failure, and the bombs were unloaded in other places.

The first attempt on London came on May 25 1917. The 3rd Bombing Squadron, 16 machines strong, left Belgium early in the afternoon and made the Essex coast about 5 P.M. On the Continent the sky was generally clear but there were thick banks of cloud over Essex. The task of navigating to London was found too difficult and the leader had to give up the attempt. He therefore turned S. over Essex and crossed the Thames about Gravesend, afterwards making a course S.E. Bombs were dropped on the Canadian camp at Shorncliffe, where there were 100 casualties. The worst effect was produced in Folkestone itself. One bomb fell in a crowded street and killed 33 people, mostly women who were out shopping. Over England the opposition to the raid was entirely without effect, but one raider was brought down in the sea by a British machine working from Dunkirk.

The second unsuccessful attempt was made on June 5; 18 machines, practically the full strength of the 3rd Squadron at that time, left the Ghent aerodromes about 2 P.M. They made the Essex coast as on the previous occasion, but this time they turned S. earlier. They bombed Sheerness with some effect, the town and dockyard both being hit several times. The guns at Sheerness succeeded in hitting one of the raiders, which fell into the river off Barton's Point. A large number of machines went up in pursuit. They were nearly all too slow and climbed too badly to do any good.

The third attempt on London was more successful. The whole of the 3rd Squadron started in the morning of June 13, taking the same course across the North Sea as before. A few machines were detached to bomb Margate and Shoeburyness. Probably this was done to confuse the defence arrangements. The main formation of 14 machines held on N. of the river to London, which was reached a little before noon. A few bombs were dropped in the East End and near the Royal Albert Docks; then, at a signal from the leader, the formation loosed 72 bombs over a small area having Liverpool Street station as its centre. The station itself was hit by three bombs. The casualties were severe—150 killed and 424 injured. One 100-lb. bomb hit a school in Poplar. On striking the building the bomb was torn in half before the fuse acted, and only half the charge exploded; even so, 17 of the children were killed. A few isolated attacks were made on the raiders without success. One machine got into touch with the enemy over Ilford, but the observer, Capt. Keevil, was killed and the pilot's gun jammed. Such gunfire as was brought to bear in the London area was badly directed and had no effect.

The next raid on London on July 7 was also successful. Twenty-four machines started; they were first seen well out to sea soon after 9 in the morning, flying at about 10,000 feet. Coming up to the coast, two machines were detached, as on the previous occasion, in order to attack Margate, where a couple of houses were wrecked. The main body of 22 machines, flying in diamond formation, crossed the Essex coast near the mouth of the Crouch river about 9.45 A.M., and they came on towards London,

gradually climbing, until they were about 13,000 ft. over Brentwood. The course of the raid ran by Enfield, where the formation turned S., over Edmonton and Tottenham. On the way to the City, St. Pancras and Shoreditch were bombed. The City itself received 16 bombs, one of them starting a small fire in the General Post Office.

The German formation was well handled in the way of making it a difficult target for the anti-aircraft guns. The machines flew in two divisions, which drew apart as they came under fire. The majority of the shell fired into the brown of the enemy burst harmlessly in the interval thus left. Individual machines flew with a switchback movement, alternately diving and climbing in order to make the task of prediction at the guns more difficult. The anti-aircraft guns fired a very large number of rounds, but produced no effect at all on the enemy. The aeroplane defences again showed a lamentable lack of plan. Eighty-seven machines went up, of all sorts and sizes. A few were efficient fighting machines. Many of them, for all the good they could do, need never have left the ground. No scheme existed by which a combined attack could be delivered. In consequence, the enemy were quite well able to beat off such isolated, though gallant, attacks as were made. They brought down two machines. All that the British pilots were able to accomplish was to finish off one lame duck, a machine that was in difficulties from engine trouble. It fell into the sea off the coast of Essex and the crew were drowned.

The failure of the defensive arrangements, or rather the complete lack of efficient arrangements, began to cause considerable agitation in the public mind. The Germans were touching the nerve centre, and the British Government found it necessary to order a complete reorganization. The London Air Defences were to be formed as a separate command. It was to include all the means of defence, both from the ground and in the air. General Ashmore was brought from France to take charge. On the formation of this new command several distinct problems presented themselves. Night raids on London by airships, although not very likely, were still possible; it was obvious that night raiding by aeroplanes would have to be faced. But the most threatening danger lay, for the moment, in day raiding by aeroplanes in force. To meet this, a line of guns was established to the E. of London some 20 m. out; and inside this line strong patrols of aeroplanes, working in formation, were organized. Careful plans were laid to ensure that the guns and aeroplanes would really coöperate and not interfere with each other. A system of signals and directing arrows on the ground was installed to assist the pilots in finding the enemy. Outer patrols of aeroplanes near the coast could deal with the homeward journey of the raiders.

The new arrangements were soon tested; on Aug. 12 a party of nine Gothas made the land near Harwich. After following the coast to the Blackwater, they turned inland for London. The communication system of the defence control worked well, and the squadrons immediately defending London were at the required height in plenty of time to meet the enemy formation. The German commander, however, would not face the defences of London itself, and turned his formation about before they reached the outer line of guns. A number of bombs were unloaded on Southend as the enemy made off, and 32 people were killed. The Germans were pursued out to sea, but an exasperating series of gun-jams robbed the British pilots of success, and the only bag was one Gotha that was flying badly and was brought down in the sea by a naval machine.

An attempt on Aug. 18 was frustrated by bad weather. Many of the German machines were blown over Holland, where some of the pilots, thinking they were over England, dropped bombs!

An abortive attack on the Midlands by eight airships on the night of Aug. 21 was followed by the last day attack on England on Aug. 22, when Capt. Kleine, commander of the 3rd Squadron, started out with 13 Gothas to bomb Sheerness and Dover. A number of naval machines turned the Sheerness bombers from their objective, and the German formation, harassed by the British pilots, wheeled south by Ramsgate. Here the anti-aircraft guns, working with great accuracy, shot down two of the raiders. A third was shot down off Dover.

The increased efficiency of the defences, both in machines and guns, decided the Germans to abandon day attacks, and they turned their attention to raiding with aeroplanes by night. Practically no answer had been found at the time to this form of attack, which had been carried on for more than a year on the western front in France. Searchlight staffs, in their then state of training, found great difficulty in picking up or holding an aeroplane in their beams. Gunfire, which could only be aimed roughly in the direction of the enemy, was so inaccurate as to be negligible. It was not thought possible to fly during darkness fast scout machines of sufficient climb and performance. Furthermore, it must be remembered that a pilot in the air at night can only see another machine when he is close to it, and that the noise of his own engine deafens him to other sounds. At the time there was no way in which the pilot could receive information from the ground. For these reasons it seemed difficult to find any means on which to base plans of defence against night aeroplane raiding.

The first group of night attacks came in the beginning of Sept. 1917, and one of these reached London itself. The raid on Sept. 2 was a quick affair at Dover and of little importance. On the following night, Sept. 3–4, about 10:30, hostile aeroplanes were reported near the North Foreland, and warnings were sent out by the central control a few minutes later when it was clear that they were coming up the Thames. Unfortunately there was serious telephone delay in getting the warning out at Chatham, and before cover could be taken a bomb had fallen on a drill hall in which a large number of naval ratings were asleep. No fewer than 130 were killed and 88 wounded.

Although on this night the defence was ineffective, certain points emerged which gave hope for the future. Three stout-hearted pilots went up in Camels, fast scout machines, and found that it was by no means impossible to handle them at night. In fact, being small and light, they were even easier to land than heavier machines, which would run on longer on the ground. The idea also was evolved of barrage fire, a curtain of bursting shell to be put up in the path of the raiders.

The last raid of this moon period, on Sept. 4, reached London. The attacking machines, between 20 and 30 in number, began to come up to the coast soon after 10 P.M. While isolated attacks were made on Dover and Margate the majority of the raiders made for London. The barrage fire, organized since the previous night, turned some of the pilots, but 10 raiders reached the metropolitan area, and bombs were dropped in widely separated localities. The City, Paddington, Stratford, Hornsey, Holloway and Regent's Park, all suffered. One bomb narrowly missed Cleopatra's Needle. Considering the magnitude of the raid, the damage caused was small, and the total casualties for the night included only nine killed.

Favourable weather and good moon conditions at the end of Sept. and beginning of Oct. 1917 produced a sustained series of raids, opening on the night of Sept. 24th with an attack on London by aeroplanes, in conjunction with an airship raid on Hull and the north.

The first aeroplanes were reported approaching Kent as early as 7 P.M., and by 8:10 P.M. some 21 machines in seven groups had come over the coasts of Kent, Essex and Suffolk. Dover was heavily attacked, the gas-works were hit and several houses were damaged. Nine at least of the pilots attempted to attack London itself, but considerable improvement had by this time been effected in putting up barrage fire, which was successful in turning back all but three of the attackers. Of these three, one dropped bombs about Deptford and Poplar, doing but little damage; the other two passed right over London from north to south. A bomb dropped in Southampton Row killed 13 people who had not taken proper cover; others fell near the Ritz Hotel and into the river opposite the Houses of Parliament. Although 27 English machines went up they failed to find any of the enemy; the gunfire brought down one of the Gothas, which fell in the river near Sheerness.

The attack on the north was carried out by 10 airships under Capt. Strasser. After concentrating off Flamborough Head six of them came over land. Although Hull was found, the raid had very little success. This was partly owing to the cloudy

weather that prevailed. But the main reason for the failure is traceable to the gradual improvement of the defences, which had driven the airships higher and higher on each successive raid. On this occasion none of them flew under 16,000 ft. while over the land. At this height the difficulties of navigation are greatly increased and the probability of successful bombing diminishes.

On the following night, Sept. 25, 10 aeroplanes attacked. Of the three that approached London, one was turned off by the barrage fire; the other two, coming in from the S., did a little damage in Camberwell, Southwark, and Bermondsey, where nine people were killed. The barrage fire at Dover was particularly successful on this night, and the attack on that place completely failed.

The attacks were continued on the 28th, when some 20 machines came over; the night was cloudy and a few only approached London; they were all kept off by the barrage fire.

The barrage was again singularly effective on the following night, Sept. 29. Out of the 18 or 19 machines that came over only four penetrated far enough to bomb London. Of the remainder a large number were turned back by the fire put up by the outer ring of London guns. The Dover guns again did well, keeping off attack and bringing one of the enemy down in flames. Thirty defending pilots went up on this night; none of them found the enemy, although one was so close to a German machine that the anti-aircraft guns had to stop firing on it.

On the next night, Sept. 30, the German pilots showed more pluck; of 25 that attacked, eight got over London and bombed places as far apart as Highgate, Edmonton and Woolwich. Considering their numbers, they were singularly unlucky in the results: six people were injured and the damage was under £8,000.

The last raid of the series on Oct. 1 was made by about 18 machines; a few penetrated the defences and dropped bombs. One attacked Highbury, damaging a large number of houses; another bombed Hyde Park and the neighbourhood. One bomb fell into the Serpentine, killing most of the fish there. Only one British pilot saw anything of the hostile machines.

During these raids a large proportion of the attackers had been turned before reaching their target. The defences had done fairly well, but they were still far from complete. The outer ring of guns was not installed on the W. of London, and it was plain that the German pilots were feeling round by the N. for this gap.

The barrage fire was expensive in ammunition and there was a doubt if the supply could be kept up. Doubts had even arisen as to the use of the barrage—one Cabinet minister describing it as "self-bombardment." A few casualties from the gunfire were inevitable until people realized that even the lightest cover would protect them from the fragments of high-explosive shell. In spite of casualties, however, it was plain that the public looked upon the barrage fire as a comfort. It is significant that a Christmas fund got up by the *Star* newspaper for the men working at the guns had to be closed down from over-subscription.

Progress had already been made in night flying, on fast machines, but the defending squadrons had not nearly reached the necessary efficiency in machines or pilots.

The "Aprons," a new defence devised after the raid of Sept. 5, were only beginning to be installed. These were screens of wire that could be raised to 10,000 ft. by Caquot balloons, and were designed to limit the range of heights in which the defending pilots would have to seek the bombers. The Central Control as organized in Sept. 1917 could give no information to pilots when once they had been sent on their patrols, but schemes to rectify this had already been initiated. On the whole, although the attack at this time had the best of it, there were reasonable hopes that this condition would not last much longer.

The airship raid of the night Oct. 19–20 1917, which became known in London as the "silent raid," has points of special interest. The weather conditions were the dominating feature both as regards the attack and the defence.

Eleven airships met on the evening of the 19th off the Yorkshire coast for an attack on the industrial centres of the Midlands. To avoid gunfire and aeroplane attack while over England, the ships flew at an immense height, well over 16,000 ft. At this altitude the efficiency of the crew is much impaired by height sickness and the intense cold. Another and fatal condition was produced by the weather. Near the ground the air was misty and there was very little wind, but at the height of the airships a strong gale was blowing from the N., and in this the Zeppelins drifted blindly S., the navigators being prevented by the ground mists from correcting their course. One airship passed over London without recognizing it and dropped a few heavy bombs; one of 50 kgm. fell in Piccadilly outside Swan & Edgar's shop and caused some casualties. Owing to the peculiar conditions of the night, sound carried very badly, and this ship crossed London unheard. Eight other airships, in the course of their southern drift, passed, without knowing it, within easy reach of the metropolis.

Realizing that, on account of the ground mists, searchlights would have no chance of lighting up a high Zeppelin, the defence ordered them to remain covered unless an airship could be heard. The London public were inclined to complain that the usual display of lights and barrage fire was lacking. The lights, had they been turned on, must have produced the worst results. They could not light up the enemy, but they would be sufficient to show the attackers where London was, and to enable them to correct their course for drift. As it was, London was saved from a combined attack and the raid ended in disaster to the attackers.

One airship only returned to Germany in the usual way; six got back after flying over Holland or across the Allied lines. The remaining four were destroyed during the following day on French territory.

Aeroplane raiding was resumed during the moon period at the end of October. An attempt on the 29th failed on account of bad weather; another on the 31st was carried out by 24 machines. Considering that a good many of them got over London, the effect was small—one woman killed and damage to the extent of about £23,000.

The weather in Dec. 1917 was generally unfavourable for long-distance raiding, and only three attempts were made on London. The defences showed steady improvement. Two Gothas were brought down by anti-aircraft gunfire during a raid in the early morning of Dec. 6 on which occasion the Germans lost a third machine in the sea on the way home. On the night of the 18th, improvements in the searchlight control and the special training of the night-flying pilots began to make themselves felt. Twenty-seven defending machines of the best performance went up, and three combats took place.

As a result, one of the Gothas was so damaged that it fell into the sea off Folkestone and was destroyed. On this night the new "Giant" aeroplane came over London for the first time. It dropped one 300-kgm. bomb in Lyall Street, near Eaton Square, making a large crater but doing little serious damage. The whole raid, however, cost London more than £300,000 in damage.

On Dec. 22 the last raid of the year was frustrated by unfavourable weather; one Gotha was forced by engine trouble to descend near Margate, where it was destroyed by the crew.

1918.—In the five aeroplane raids of the first quarter of 1918 there was a tendency to replace the smaller Gotha machines by the new "Giants." A Gotha was destroyed by a defending aeroplane on Jan. 28. During this raid a bomb dropped by a Giant fell on a building in Long Acre that was being used as an air-raid shelter, and 38 people were killed.

On the following night, Jan. 29, one of the Giant machines was pursued half round London by four of the defending scouts. The reason for its escape is curious. The British pilots saw over their sights a machine they imagined to be of Gotha size. The actual machine, being a Giant and very much larger, was therefore a good deal farther off than they thought, and they were firing at too long a range to be effective. The crew of the Giant became panic-stricken and were within an ace of landing when the British machines drew off.

Three Giants, unaccompanied by any smaller machines, attacked on Feb. 16; the only one that penetrated to Lon-

don demolished a house in Chelsea Hospital with a 300-kgm. bomb.

The raid of March 7 1918 was remarkable as being the only occasion on which aeroplanes attacked London in the absence of any moonlight. The navigators of the attacking Giants were helped by a bright aurora. This made the night unusually light, and gave a constant bearing of fair accuracy to the pole. Warrington Crescent was badly hit, most of the houses being wrecked.

To turn to the airships, the disaster of Oct. 19–20 1917 was followed by the destruction of four more ships by explosion in their sheds, and raiding was not resumed until the nights of March 12 and 13 1918. Both these raids were made at an immense height, and although Hull and West Hartlepool were bombed, the damage did not amount to much. The casualties comprised nine killed on the two nights.

Five airships of the newest and largest type, under Capt. Strasser, attacked the Midlands on the night of April 12. Although more than seven tons of bombs were dropped in the neighbourhood of big towns, the result was very small, and only five people were killed.

The end of the airship raiding came on Aug. 5–6 1918. Five ships came up to the coast of Norfolk, no bombs were dropped on land, but L70, the latest word in airship construction, was destroyed, with Capt. Strasser on board, by Major Cadbury, flying a DH4 machine.

In the great aeroplane raid of May 19 1918 the Germans made their maximum effort in this form of attack; between 30 and 40 Gothas of the 3rd Bombing Squadron took part, with at least two Giant machines. Thirteen of the raiders managed to get over London. The casualties included 49 killed, and £130,000 worth of damage was done in the London area alone. But the defence had by now made very real progress. Eighty-four aeroplanes, nearly all of excellent performance, went up in pursuit, and all landed safely. The anti-aircraft guns fired upwards of 30,000 rounds. The plans worked well in that the defending pilots were assisted instead of being hampered by the gunfire and searchlights. The Germans lost seven machines—three shot down in air combat, three destroyed by gunfire, and one from engine failure.

This success of the defence was final, and London was saved from further bombing. The Germans turned their attention to Paris, which now sustained a long series of raids.

A new system of defence control was in course of being installed in London at this time, but it did not come into full operation until Aug., and it was therefore never tested in an actual raid. It provided a method by which the defence commander could follow the course of raiding machines, and could instantly transmit information and orders to the pilots in the air by wireless telephone. It was calculated that this system would increase the power of the defence at least fourfold.

A proof of the efficiency of defence by aeroplanes, assisted by a good organization on the ground, was furnished by a squadron, manned by pilots trained in the London methods, that was sent to France in June 1918 to cope with night bombing near the line. In a very short time they accounted for 26 German machines, and they practically stopped bombing in their area, with no loss to themselves.

Conclusion.—We have now traced the way in which raiding and defence grew up together, and the eventual success of adequately equipped and organized defences. In addition to casualties—1,413 killed, 3,407 injured in all—and damage, the German raids on England produced actual results by no means negligible. A night raid stopped munition work over a large area. In order to establish a defence, men and material were kept back from France. This was particularly felt in the case of aeroplanes and pilots. Two hundred aeroplanes of the best performance and 200 highly trained pilots were available about London at a time when they would have been of the utmost value on the western front. The moral effect of raiding is found to depend not so much on actual damage as on the success or ill-success of defensive measures. In London, the barrage, the "aprons," and the aeroplane defence did much to allay fears that had arisen when there was apparently no answer to the attacks. (E. B. A.)

AIRSHIP: *see* AERONAUTICS.

AITKEN, JOHN (1839–1919), British physicist, was born at Falkirk Sept. 18 1839. He was educated at Falkirk grammar school and Glasgow University, and trained as marine engineer at R. Napier & Sons, Glasgow. He lived at Falkirk, where he carried out his great experiments on atmospheric dust in relation to the formation of clouds and mists (1882), on the formation of dew (1885, *see* 8.136) and on the laws of cyclones (1891). His instrument for counting the dust particles in the air (*see* 8.714, 18.279) has been utilized in principle by many later workers. He also invented new forms of thermometer screens and powerfully aided the development of meteorology. He was elected F.R.S. in 1889 and was awarded the Royal medal in 1917. He also received the Keith medal (1886) and Gunning prize (1897) from the Royal Society of Edinburgh, in whose *Transactions and Proceedings* most of his valuable contributions were published. He died at Falkirk Nov. 14 1919.

AKHWAN MOVEMENT, a religious revival or reform, confined mostly to the Nejd districts of Arabia. The term *akhwan*, or *ikhwan*, signifies "brethren," and the tenets of the brotherhood are those of Wahabism revived and intensified (*see* 28.245). The movement, recognized by Ibn Sa'ud, Emir of Nejd, had taken definite shape after 1910; and in 1921 it still seemed likely to have far-reaching effects upon the attitude of the people of Central Arabia towards other Arabian communities and even to the outer world.

ALABAMA (*see* 1.459).—In 1920 the pop. was 2,348,174 as against 2,138,093, in 1910, an increase of 210,081, or 9·8 %, as compared with 309,396, or 16·3 %, in the preceding decade. Although the proportion of urban pop. was greater than in 1910, yet in spite of the marked development of mining and manufacturing interests, more than three-fourths of the inhabitants were still rural and chiefly agricultural. The urban pop. (inhabitants of cities of 2,500 or more) was 509,317; the rural, 1,838,857. The growth of pop. in the chief cities is shown in the following table:—

	1920	1910	Increase per cent.
Birmingham	178,270	132,685	34·4
Mobile	60,151	51,521	16·8
Montgomery	43,464	38,136	14·0
Bessemer	18,674	10,864	71·9
Anniston	17,734	12,794	38·6
Selma	15,607	13,649	14·2

The distribution of pop. by race was as follows: whites, 1,447,032; negroes, 900,652; Indians, 405; Chinese, 59; Japanese, 18; all others, 8. During the decade 1910–20 the white pop. increased 17·8 %, while the negro pop. decreased 0·8 %, due to male negro migration to northern industrial centres.

Agriculture.—There were 256,099 farms in 1920; 262,901 in 1910, a decrease due to the negro migration noted above, but there was a marked increase in total production. The state Department of Agriculture estimated that in 1920 there were harvested 5,630,000 tons of commodities compared with 5,203,000 tons for the year 1910. The same department made the following estimates of the acreage, production and value of crops in 1920:—

Crops	Acres	Production	Value
Corn	4,277,000	67,234,000 bus.	$67,057,000
Cotton	2,868,000	660,000 bales	53,515,000
Cottonseed	—	296,700 tons	7,839,000
Peanuts	409,700	9,024,000 bus.	5,936,000
Hay	1,440,000	3,324,000 tons	27,123,000
Velvet beans	743,700	440,100 tons	7,914,000
Cowpeas	532,200	5,113,000 bus.	9,622,000
Irish potatoes	47,900	3,215,000 bus.	11,250,000
Sweet potatoes	179,800	17,585,000 bus.	16,939,000
Sorghum syrup	99,900	8,917,000 gal.	8,340,000
Sugar-cane syrup	59,700	10,298,000 gal.	10,643,000
Oats	366,000	6,833,000 bus.	6,740,000
Wheat	68,000	680,000 bus.	1,594,000
Soy beans	23,000	227,000 bus.	588,000
Tobacco	3,000	2,100,000 lb.	420,000
Total harvested	11,117,900		$235,520,000

The above estimates did not include the acreage grazed or "hogged" and not harvested, which the state department of Agriculture placed in 1920 at 1,344,000 ac. with an approximate value of $20,001,000. The Statistical Bureau of the U.S. Department of Agriculture estimated the value of all crops in Alabama in the year 1920 at $240,000,000.

Industries and Transportation.—Three new lines of material progress during 1910–20 were notable: (1) The use of hydro-electric power; (2) shipbuilding; and (3) the utilization of the canalized Warrior and Tombigby rivers from the heart of the inland mineral district to tidewater at Mobile. A private corporation completed a great dam across the Coosa river and was in 1920 delivering electricity for lighting and power purposes to the chief centres of population and industry in northern and central Alabama; and the same company in 1921 began another great dam across the same river which would increase greatly the power available. In the meantime the U.S. Government undertook the famous "Wilson dam" across the Tennessee river at Muscle Shoals. The impetus given to shipbuilding at Mobile continued after the World War; and the great shipyard at Chickasaw, a suburb of Mobile, was in 1920 steadily sending down the ways ships of heavy tonnage, made from steel fabricated in the Birmingham district and barged down the Warrior and Tombigby rivers. The growth of down-stream tonnage of coal, iron, steel and timber on the canalized Warrior river continued for a year or two under private enterprise; but the closing months of the year 1920 marked a new era when the first vessel of a fleet of Government-owned and -operated self-propelling barges made its way down the Mississippi river to New Orleans and into the Gulf, then to Mobile and up the rivers to Birmingham and Cordova in the heart of the Warrior coal-fields. A balanced tonnage, up and down stream, was steadily being developed in 1921 by the transhipment at Mobile of manganese ore from Brazil, for use in making high-grade steel in the Birmingham district, and by the establishment of an all-water freight rate from New York and other eastern points, *via* Mobile, to the various river ports.

Mineral Production.—The Geological Survey of Alabama reported a decrease in 1918, as compared with the preceding year, in quantity but an increase in value of most of the mineral products of the state. In 1918 the production of coal was 19,184,962 short tons valued at $54,752,329, with a coke production of 4,892,589 short tons valued at $28,394,272. The iron ore mined in 1918 amounted to 6,121,087 long tons with an estimated value of $15,334,561; the gross tons of pig-iron marketed amounted to 2,645,179, valued at $80,893,678. Another important mineral product was graphite, of the crystalline variety, the value of which in 1918 was $999,152 as compared with $719,575 in 1917. It is estimated that Alabama furnished over 60% of the domestic graphite used in the World War.

Education.—The impetus given to public education, under the administration of Governor Comer (1907–11) by the creation of a system of county high schools and by more liberal appropriations both for the common schools and for the institutions of higher education, lost none of its momentum under his successors. In the beginning of Governor Kilby's administration the Legislature passed an Act, approved Feb. 6 1919, creating a commission of five members, appointed by the governor, to make a study of the educational system of the state with the object of determining its efficiency. The commission in turn invited the U.S. Bureau of Education to accept the task. The result was a series of Acts passed by the Legislature in 1919, constituting the School Code of Alabama. Among the most important of these Acts was one providing for a state Council of Education to coördinate the efforts of the university of Alabama at Tuscaloosa, the Alabama Polytechnic Institute at Auburn, and the Alabama Technical Institute and College for women at Montevallo, by assigning to each special fields for higher education. The efficiency of the public-school system of the state was perhaps best shown by the steady reduction of illiteracy. The total number of illiterates in 1920 was 278,082, of which number 210,690 were negroes, 65,394 native whites, and 1,893 foreign-born whites. During the two-year period between the school censuses of 1918 and 1920, the percentage of literates in the total population, white and negro, between the ages of 10 and 21 years, increased 5.2 per cent.

Taxation and Finance.—Owing to the limitation in the constitution of 1901 of the rate of state taxation upon real and personal property to 0·65% upon assessed values, the Legislature in 1919, in an effort to increase revenues, incorporated in the general revenue bill among the license or privilege taxes a tax of two cents per ton on coal and three cents per ton on iron mined in the state, payable monthly. At the same session a graduated income tax, ranging from 2% to 4% was levied; but the Supreme Court decided that it was repugnant to the constitution and null and void. By a decision of the Supreme Court handed down Feb. 3 1921, the amendment to the constitution hereafter noted, authorizing the issue of $25,000,000 highway improvement bonds, was declared to have been irregularly adopted and not a part of the constitution; but as the decision was rendered by a divided bench of four judges to three, an application for a rehearing was pending, and if not granted, an effort was to be made to have the amendment re-submitted for adoption according to the strict terms of the constitution by an extra called session of the Legislature.

History.—During the period from 1910 to 1921 the Government of Alabama remained in the control of the Democratic party, with little more than nominal opposition by the Republican party, the educational, property and other qualifications for voters under the state constitution of 1901 having eliminated the bulk of the negro Republican voters. It was only in the presidential election of 1920 that there were indications of the development of a real white Republican party in the state. In that election that party polled practically one-third of the vote cast, 31·9%, thus securing the privilege of a primary for the nomination of candidates in the next election at the expense of the state Government. Before this time factional differences in the Democratic party were fought out in the primary elections under state supervision, and the general elections were merely formal ratifications of the choice made in the primaries. It was not easy to distinguish clearly between the two leading factions that developed in the dominant party, but perhaps the terms "Conservative" and "Progressive" sufficiently indicate the line of cleavage. The former insisted on the fullest protection to vested financial interests, and before the adoption of the Eighteenth (prohibition) Amendment to the Constitution of the United States, on a liberal policy of "local option" in the manufacture and sale of alcoholic beverages. The latter stood generally for strict control, by the state, of corporate capital, especially in the matter of railway rate regulation, and for prohibition of the liquor traffic. Several amendments to the state constitution of 1901 were adopted during this period, most of them dealing with matters of local interest to counties and cities. Two, however, were general in their scope: one providing for local option by counties and school districts as to increased taxation in the interest of public schools; the other authorizing the issue of state bonds to the amount of $25,000,000 for the construction of a complete system of highways, thus enabling the state to secure the national appropriations in aid of that policy. At its regular session in 1919 the state Legislature refused to ratify the Nineteenth Amendment to the Constitution of the United States providing for woman suffrage; but as soon as the requisite number of states had made it a part of the Constitution, Governor Kilby called a special session of the Legislature (1920), which promptly passed an Act providing for the registration of women voters and for otherwise carrying into effect the provisions of the Amendment.

The total number of men enlisted for the World War in the state and inducted into the army was 73,811. As this did not include National Guard commands or other volunteers, the Alabama Department of Archives and History estimated that approximately 10% should be added. Alabama subscribed a total of $99,838,400 to the Liberty and Victory loans.

Recent governors were Braxton B. Comer (Dem.), 1907–11; Emmet O'Neal (Dem.), 1911–5; Charles Henderson (Dem.), 1915–9; Thomas E. Kilby (Dem.), 1919– (T. C. McC.)

ÅLAND ISLANDS (*see* 1.469).—The alarm that had been felt in Sweden for some years at Russia's projected military works in the Åland Is. was intensified in 1915 when Russia openly began the construction of fortifications. Sweden protested against this breach of the Convention of Paris (1856), and Russia's assurance that the fortifications were merely temporary did not allay Swedish hostility towards Russia which at times threatened a crisis. The Russian revolution of 1917 diverted attention from the fortifications to the larger question of the sovereignty of the islands. In Aug. 1917 the Åland islanders took steps to consider reunion with Sweden, and as a plebiscite in Dec. showed 95% of the population in favour of the proposal, a petition to that effect was presented to the King of Sweden in Feb 1918. The King in reply echoed the hope of the deputation that a solution of their desires might be found "in concert with free and independent Finland." In the same month Sweden sent a military expedition to the islands to protect the population from outrages by the Russian Bolshevik garrison with which a small Finnish White force was unable to cope. The Russians were sent to Åbo and the Finnish troops to northern Finland *via* Sweden. On the arrival early in March of German troops by invitation of the Finnish Whites, the Swedish force withdrew. The German garrison remained until Oct.

1918. The Treaty of Brest-Litovsk (March 3 1918) and the subsequent treaty between Germany and Finland (March 7 1918) both stipulated that the fortifications on the islands should be removed and not subsequently rebuilt. But the work of demolition was repeatedly delayed. The Finnish Government opposed the Ålanders' wish for union with Sweden, but proposed to compromise by making the islands into a separate Finnish province. The Diet persisted in this policy, and passed a bill for self-government for Åland in May 1920. Meanwhile the appointment of a Finnish military governor caused resentment, which was aggravated (July 1918) by attempts to call the Ålanders for military service on the mainland. They refused to obey, at the same time expressing their willingness to serve in the islands under Swedish-speaking officers. Many of the inhabitants fled to Sweden in order to escape service. In Nov. 1918 the Ålanders appealed to the United States, Great Britain, France and Italy, relying on the right of self-determination. An appeal to Finland at the same time drew an equivocal reply. In Feb. 1919 the Ålanders submitted their case to the Supreme Council in Paris. Sweden supported their claim. The Peace Conference declined to deal with the matter, which was then referred to the League of Nations. A commission of three jurists appointed by the League reported (Sept. 1920) that the Council of the League was competent to make recommendations since the dispute did not refer to a matter left by international law to the domestic jurisdiction of Finland. The League thereupon appointed a commission to examine the question.

Opinion in Finland among both Finns and Swedes was strongly opposed to the cession of the islands, and it was argued that to yield to the demand for self-determination of a fraction of the Swedish population of Finland (about one-tenth) would be to reduce the doctrine to an absurdity. At the same time the opposition of the Swedes in Finland to the Ålanders' desire might be regarded as biased by unwillingness to lose the weight of their vote and so lessen Swedish influence in Finland. Finland also maintained that her sovereign rights over Åland were not affected by Russian domination in Finland or by subsequent events, and that Finland was not one of the "new" states that arose as a result of the World War; and that in consequence the Åland question was purely a domestic one in which no other state nor the League of Nations was competent to intervene. On the other hand the Ålanders showed themselves virtually unanimous in their desire for union with Sweden, to which they were closely allied in race, language and to a great extent in trade, and they maintained that their islands were sufficiently distinct from Finland geographically to give them the right of self-determination.

The commission, after visiting Stockholm, Helsingfors, and the Åland Is., presented its report to the Council of the League at its session in June 1921. On June 24 the Council announced its decision that the islands were to belong to Finland, but that they were to be neutralized from a military point of view and given full guarantees of unfettered autonomy. M. Branting, on behalf of Sweden, said Sweden would bow to the League's ruling under protest, and M. Hymans was appointed to preside at a committee of Finns and Swedes to discuss details of the guarantees.

For a general account of the islands reference may be made to Handbooks prepared under the direction of the Historical Section of the Foreign Office, No. 48, *Aland Islands;* also *Atlas de Finlande,* with text in French (1910). The Finnish side of the present dispute is set forth in *The Åland Question and the Rights of Finland* (1920). See also Sven Tunberg, *Les Îles d'Åland dans l'Histoire* (1919), and E. Sjaestedt, *La Question des Îles d'Åland* (1919).

(R. N. R. B.)

ALASKA (*see* 1.472).—The most important events in the history of Alaska in the ten years ending with 1920 were:—(1) the extension of surveys and investigations of resources over nearly half of the total area (586,400 sq. m.)[1]; (2) the change in the public land policy, which no longer prohibited the utilization of Alaska's coal, petroleum and water powers; (3) the granting of a measure of home rule to the people of Alaska; (4) the improvement of transportation by the construction of a Government railway from an open port on the Pacific to navigable waters on the Yukon river, by the construction of many wagon roads (total roads and trails 4,900 m.) and by the installation of many lights and other aids to navigation (total 547); and (5) the great advance of her copper and salmon-fishing industries, and of gold mining until 1916.

Public Land Policy.—The political history of Alaska has largely centred in a struggle for more liberal land laws. In early days it had been considered for the best interests of Alaska to transfer the lands to private ownership as quickly as possible without too close a scrutiny of the means employed. This policy was completely reversed as a result of the conservation movement inaugurated under President Roosevelt. The aim of the movement, as first defined, was to prevent waste of natural resources; but this issue proving too academic to make a popular appeal, it gradually veered to a protest against corporate control of lands and resources. Though supported in the beginning by the best element in the nation, it ultimately became involved in the bitter struggle between the Roosevelt and Taft wings of the Republican party. As practically all the lands of the Territory were still owned by the Government, the withholding of the most valuable of these from settlement and development played havoc with her industries. Curiously enough, the most ardent of the conservationists failed to recognize the urgent importance of conserving the salmon and halibut fisheries. As it was, the withdrawal of coal, oil and good timber lands as well as of water powers left the Territory with only metalliferous deposits and fisheries on which to base its industries. A very important by-product of the conservation movement was the development at Washington of a mania for the establishment of reservations in Alaska. In this way there were set aside for various purposes, exclusive of mineral or forest withdrawals, some 40,000 sq. miles. For many years the Alaska conservation issue remained at a deadlock between the executive and legislative branches of the Government. Meanwhile Alaskan industries languished. With an abundant supply of fuel close at hand, she was forced to import coal and petroleum at great cost; her pulp wood was rotting in the forest, her water powers were undeveloped. Only gold- and copper-mining and salmon-fishing increased. Finally during the Wilson administration a leasing policy for coal and oil lands and water powers was established by law. At about the same time the shortage of paper had a liberalizing influence on the regulations relating to the sale of timber from the national forest. In 1921 the new laws were too recent to allow an estimate of their effect.

Government.—The struggle of Alaska to attain representation in Washington, lasting nearly 40 years, resulted in 1906 in the authorization of an elected delegate to Congress. At each biennial election which followed, home rule was the only important issue, until finally in 1912 an Act was passed granting a territorial government. This continued the governor as a presidential appointee, and (unwisely, though in accord with American tradition) provided for a bi-cameral Legislature. The upper chamber, or Senate, consisted of two senators from each of the four judicial districts, serving four years. Sixteen representatives formed the lower chamber, or House of Representatives, four elected for two years from each judicial district. This equal representation for each of the judicial districts gave the less-populated areas of the interior an unjust preponderance in the Legislature, and in many instances worked against the best interests of the Territory as a whole. Congress in the organic Act expressly retained the right of repealing all laws enacted by the Alaska Legislature. Furthermore, the Territory was denied the right to enact laws relating to the excise, game, fish, fur-

[1] Most of the inland surveys and investigations, as well as a part of those made along the shore line, were done by the U.S. Geological Survey, which between 1910 and 1920 mapped about 50,000 sq. miles. The Coast and Geodetic Survey charted the general features along the entire coast-line and covered about 10% of it in detailed surveys of important harbours and principal routes of navigation. In 1913 the International Boundary Commission completed the survey of the Alaska-Canadian boundary.

bearing animals, or the existing Federal licence tax. It was provided that the capital should be at Juneau. The first session of the territorial Legislature was in March 1913, and the first law passed gave the franchise to women. Since that date the most important legislation has related to mining, hours of labour, workmen's compensation, banking and education. Heavy taxes were also imposed on the salmon-fishing industry, and from these the Territory derived a large part of its income. In 1916 the Legislature authorized a plebiscite on the prohibition of the sale, transportation and manufacture of all alcoholic beverages. The vote was in the affirmative by 7,958 to 4,431. As the Legislature had no power to change the excise law, a petition was submitted to Congress, which passed a dry law for Alaska in 1917.

Education.—The white schools of Alaska were in 1920 under territorial management and were supported by local taxes. Even most of the small settlements had schools, and five of the larger towns supported high schools. The Territory founded an agricultural and mining college at Fairbanks in 1918, but as funds were appropriated only for the erection of a building, the school had not been opened up to 1920. In 1919 there were 62 white schools in the Territory, with 147 teachers and 2,713 pupils. The education of Alaskan Indians and Eskimos was in the hands of Federal agencies. In 1919 there were in the Territory 70 Indian schools, too few to accommodate the children of the 25,000 natives. The Federal Government also made some provision for medical service for the natives, and maintained six small hospitals for the purpose. In addition to the Government schools, about 35 sectarian missions were maintained by various churches for the benefit of the natives. Many of these had boarding-schools and a few had hospitals.

Population.—In 1920 the pop. was 54,899, a decrease of 9,457, or 14·7 %, from 64,356 in 1910. The whites numbered 29,000, as against 36,400 in 1910; the Indians and Eskimos 25,000, as against 25,331 in 1910; and the balance was of Mongolian and other races. Juneau, the capital and an important mining centre, was the largest town, with a pop. of 3,058. Ketchikan, the most important fishing centre, had 2,458. Anchorage and Seward, on the Government railway, had respectively 1,685 and 652. Cordova, the coastal terminus of the Copper River railroad, had 955. Fairbanks, the chief mining town of the interior, had 1,155. Nome, on the Seward peninsula, had 852. The white population of Alaska steadily increased until 1915, when it exceeded 40,000. Subsequent losses were due to:—(1) enrolment in military service of about 3,500 men, few of whom returned; (2) high wages in the States; and (3) decrease in the gold-mining industry. While in 1915 about 9,600 men were employed in Alaska mines, there were only about 3,000 in 1920. In addition to the permanent residents of Alaska, between 25,000 and 30,000 men annually visit the Territory to find employment, chiefly in fishing, but also in mining. There were also 2,000 or 3,000 tourists each summer.

Mountaineering.—The mountain ranges include a number of the highest peaks on the continent, which have exercised a fascination for the mountaineer. Many unsuccessful attempts were made to reach the summit of Mt. St. Elias (18,024 ft.) before the Italian Duke of the Abruzzi finally succeeded in 1897. Mount Wrangell, Alaska's highest volcano (14,005 ft.), was ascended by Robert Dunn in 1908; and in 1912 Dora Keen climbed Mt. Blackburn (16,140 ft.). Several attempts were made between 1903 and 1910 to climb Mt. McKinley, the highest peak in North America. William Taylor and Peter Anderson, prospectors, reached the summit of the N. peak (20,000 ft.) in 1910, and Hudson Stuck and Harry P. Karsten the summit of the S. peak (20,300 ft). in 1912. Katmai volcano, in the central part of the Alaska peninsula, had been entirely dormant for more than a century previous to 1912. On June 6 of that year, without previous warning, the top of the volcano blew off and ejecta were thrown for at least 1,500 m., while the fine volcanic dust encircled the world in the upper atmosphere. Though one of the greatest eruptions in historic times, it caused no loss of life, because the ejecta fell chiefly on the sea and in uninhabited regions.

Railways.—At the close of 1910 there were 371 m. of railway in Alaska. This included 20 m. of the White Pass Railroad (narrow gauge) which ran inland from Skagway across the international boundary to White Horse in the Canadian Yukon (110 miles). This line, while primarily serving Canadian territory, gave access during the open season of navigation to the settlements on the lower Yukon. The Copper River & North-Western Railroad (standard gauge), extending from Cordova on the coast to the Chitina copper belt (196 m.), was completed in 1910. Another line, the Alaska Northern Railroad (standard gauge), was built for 71 m. from the town of Seward, and then went into bankruptcy. A narrow-gauge railway 45 m. in length, connecting the town of Fairbanks with the gold-mines, was completed in 1904, and was later purchased by the Government. About 130 m. of railway were laid in various parts of the Seward peninsula and subsequently abandoned. In 1912 Congress authorized a special commission to report upon the Alaska railway situation. The commission recommended that 733 m. of railway be built, estimated to cost $35,000,000. The project included two lines: one to extend from Cordova to Fairbanks, using the Copper River railroad, with a branch to the Bering River coal-field; the other to run from Seward (utilizing the existing stub line) through the lower Susitna valley to navigable waters of the Kuskokwim river, with a branch into the Matanuska coal-field. In 1914 authorization for not more than 1,000 m. of railway construction, the cost limited to $35,000,000, was granted by Congress. A new commission was then appointed, and after extensive surveys confirmed in general the former estimate of cost. In 1915 the administration announced the selection of a railway route from Seward to Fairbanks. The estimated cost of this was about twice as much as for the route from Cordova to Fairbanks. Railway construction was begun in 1916, and by 1920 383 m. out of a total of 467 m. had been completed. The entire system was to be finished by 1923. The choice of the more expensive route and a policy of using only construction of the highest type brought the cost, at war prices, up to $52,000,000, with a probability that it would cost several millions more.

Commerce.—The value of the total products of Alaska from the annexation in 1867 to the close of 1920 was more than $1,000,000,000. In 1919 Alaska produced minerals, furs, fish, etc., to the value of $71,000,000. During the same year the value of her imports was $38,925,000, of which $1,449,000 was for merchandise from foreign countries. In 1919 25 American vessels (tonnage 32,444) and 5 Canadian vessels (tonnage 4,870) were operated as common carriers to Alaska ports. These carried 295,490 tons of freight and 32,803 passengers northbound, and 278,200 tons of freight and 31,717 passengers southbound. In the same year a total of 370 private vessels (tonnage 118,169), chiefly engaged in fisheries, were operated in the Alaska service and carried a total of 465,000 tons of freight (north- and southbound). Nine river steamers were operated on the Yukon in the summer of 1919. These carried a total of 9,690 tons of freight and 1,370 through-passengers. One steamer was operated on the Kuskokwim river in 1919.

Mining.—From its small beginning at Juneau in 1880 up to the close of 1920 Alaska mining yielded a total value of $460,000,000. Of this 96 % is to be credited to gold and copper deposits. But the mines have also produced silver, platinum, palladium, tin, lead, antimony, tungsten, chromite, coal, petroleum, marble, gypsum, graphite, barite and sulphur; and development work was done on deposits carrying nickel, iron and molybdenite. The value of the total annual mineral production rose from $16,890,000 in 1910 to $22,000,000 in 1920. Alaska mines have produced $320,000,000 worth of gold, of which $220,000,000 is to be credited to the placers. The largest gold production of any one year (1906) was $22,000,000. Since 1916, when the value of the gold output was $17,200,000, gold-mining has steadily declined, being only $8,000,000 in 1920. This decrease was due to the world-wide stagnation of gold-mines caused by the economic conditions brought on by the World War, and to this primarily is due the loss of population already referred to. In the past about 60 % of Alaska's population has directly or indirectly been supported by the gold-mining industry. The U.S. Geological Survey estimated the value of the placer gold reserves of Alaska to be at least $360,000,000. This was in addition to the gold in vein deposits whose value could not be estimated. Auriferous lodes have been found in many parts of Alaska and developed in a small way. The only large gold lode mines were in south-eastern Alaska. Before the war there were near Juneau a number of large gold-mining enterprises operated at a lower cost than any others in the world. The small profits per ton were offset by the very large tonnage of ore. With the increased cost of labour and supplies mining greatly decreased at Juneau. Alaska copper-mining began in 1901, and up to the close of 1920 had produced 308,000 tons of metallic copper, valued at $127,000,000. Stimulated by the war demand and high prices, the mines made their largest output of copper in 1916 (59,900 tons). In 1920 the Territory produced 35,000 tons of copper, chiefly from four large mines. Copper ores are widely distributed in Alaska, but most of the deposits are as yet inaccessible. The richest copper-mines thus far developed were those of the famous Kennicott group in the Chitina district. There are high-grade bituminous coals and some anthracite in both the Bering River and Matanuska fields, the latter within reach of the Government railway. All Alaska coal lands were withdrawn from entry in 1906, and patent was refused to all but a few claims previously entered. This interdict lasted until 1913, when a coal-leasing law was enacted. Coal-mining was still in the development stage in 1921, the entire production up to that time being only 300,000 tons. The output of 1920 was 70,000 tons, chiefly taken from a Government mine in the Matanuska field. The total

estimated reserves of coal in the surveyed fields of Alaska were 19,590,000,000 tons, of which 12,610,000,000 tons were lignite. Oil seepages were found at four localities on the Pacific seaboard: namely, Yakataga, Katalla, Iniskin Bay and Cold Bay, and also at several places near the N. Arctic coast. Only at Katalla, 60 m. E. of Cordova, was there any considerable drilling; here there was some oil production from the only petroleum claim to which patent had been granted. The withdrawal in 1911 of oil lands from entry stopped all development. In 1919 an oil leasing law was passed, and the development of producing fields was expected to follow. The total Alaska oil production to the close of 1920 was 60,000 barrels. Meanwhile, the Territory was consuming about 5,000,000 barrels of imported petroleum products annually. The only considerable production of tin in North America was from the York district on Bering Sea, near Cape Prince of Wales. A total of 1,000 tons of metallic tin had been mined since operations began in 1900. Alaska had produced in all about 9,800,000 oz. of silver and 5,000 tons of lead. This had practically all been won from gold and copper ores, for no large deposits of silver and lead had been developed. The mining of platinum and related minerals began in 1916, since which time about 1,500 oz. of those minerals had been produced. Demands of the World War led to the mining of some antimony, tungsten and chromite ores, but with the decreased value of these metals after the peace these operations ceased. Quicksilver mining had been carried on in a small way for many years. There were in south-eastern Alaska extensive deposits of high-grade marble which had been quarried on a large scale.

Fisheries.—The total value of fish products which had been marketed (1867–1919) was $418,000,000. In 1919 the output of the fisheries brought in $50,282,000, of which $45,000,000 was for salmon. Two small salmon canneries were built in Alaska in 1879; by 1919 the number had grown to 134. The fishing industry in 1919 employed 28,500 persons, of which 3,875 were Indians. Ninety per cent were engaged in salmon canning. The canneries can be operated during only from two to four months of the year, and much the larger part of the labour is imported. About 90% of the salmon caught in Alaskan waters are canned. In 1911 a total of 44,000,000 salmon were caught in Alaskan waters. This was increased in 1918 to 101,500,000, but fell to 58,000,000 in 1919. The enormous catch of 1918 was due to the stimulus of the war demands, and was undoubtedly in excess of the number that can be taken without permanently impairing the industry. In the early days of the salmon-fishing there were no restrictions, but, beginning in 1902, laws were passed to regulate the fisheries. The latest law (1906) was a great improvement on those preceding, but is by no means adequate. As an additional precautionary measure, hatcheries were established. There were five of these operated in 1919, at which were hatched and liberated 95,580,000 young salmon. In theory this should suffice to provide for the annual catch, but in practice only a small part survive as adult fish. The importance to the nation of conserving the Alaska salmon fisheries is indicated by the fact that in 1919 a total of 133,680,000 lb. of salmon were shipped from the Territory. The halibut fisheries are being depleted even more rapidly than the salmon. About 14,000,000 lb. are caught in Alaska and adjacent waters each year. The industry employs about 900 men and 90 small vessels. The halibut is all shipped fresh; much of it to the E. coast markets, and some to Europe. The number of cod on the Alaska cod banks is enormous, but as yet they have been little exploited. The total annual catch is between 10 and 11 million pounds, and the number of men employed is only a few hundred. Herring are found in great abundance as far north as Bering Strait. Whale-fishing along the coast, once a very important industry, is now limited to a few shore stations, where the catch is chiefly utilized for making fertilizer. There has been some canning of crabs and clams. The Alaska crab, which is the same species as that found in the Pacific waters farther south, is especially delicious.

Forest Products.—The national forests of Alaska include all the best timber lands (total area 20,000,000 acres). These are estimated to contain 77,000,000,000 ft. (B.M.) of timber suitable for lumber and pulp. Up to 1921 these forests had been used almost solely for local use, though some spruce had been exported for the manufacture of aeroplanes and other articles which require great toughness of fibre. It was officially estimated that these forests were capable of furnishing 2,000,000 cords of pulp-wood annually. A pulp-wood industry was developed in south-eastern Alaska in 1920.

Agriculture.—Alaska contains extensive farm lands adapted to raising the hardier varieties of wheat, oats, barley, rye, potatoes and other hardy vegetables, and forage crops. The most promising agricultural fields were in the Tanana and Susitna valleys, both tributary to the Government railroad. Tests in this region showed that sugar beets can be matured that contain a high percentage of sugar. Extensive areas of agricultural land are also found in other parts of the Yukon basin, and smaller patches here and there in the Pacific coastal region. The best-developed farming area was in the neighbourhood of Fairbanks, where about 2,000 acres of land were under cultivation. Here a hardy variety of wheat was matured during five successive years, and part of the flour for local consumption was made in a small mill. There is an abundance of good grazing land in the interior, but the period of winter feeding is about eight months. Up to 1921 the only cattle introduced were small herds used for dairying. The Government recently began the experiment of introducing yaks into this region. The domesticated reindeer herds numbered in 1920 92,933 valued at $2,238,562 against 22,107 in 1910. This was the natural increase from the original 1,200 imported by the Government between 1892 and 1902. About 70% of the herd was owned by the Eskimo, for whose support the animals were first imported. Some reindeer meat had been exported, and the amount promised to increase.

Fur Industry.—Between 1867 and 1920 Alaska produced furs to the value of $90,400,000, of which $53,000,000 represents seal skins taken on the Pribilof Is. in Bering Sea. Up to 1910 the Government leased the seal-catching privileges on the Pribilof Is. to private corporations, which killed 2,320,028 seal and paid the Government $9,474,000 in royalties. The land killing of seal was properly restricted, but pelagic sealing by vessels of various nationalities destroyed an additional 976,000 seal. Pelagic sealing, being on the high seas, could not be controlled by the American Government; therefore a treaty was signed in 1911 between the United States, Great Britain, Russia and Japan, abolishing it and providing that the United States was to pay to Great Britain and Japan each 15% of the catch made on the islands. Since 1910 killing has been prohibited on the Pribilof Is. except by Federal agents. Thanks to these provisions, the seal herd has increased from 215,000 in 1912 to 524,000 in 1919. In the latter year the Government sold 19,157 dressed seal skins, for which $1,501,600 was received. The value of all furs shipped in 1919, besides the seal, was $1,500,000, of which over half is to be credited to the fox. Fur farming increased rapidly during the World War owing chiefly to the high value of furs. Most of the successful farms are on small islands, and practically all are devoted to the raising of foxes, though attempts have been made to raise both mink and marten.

(A. H. Br.)

ALBANIA (*see* 1.481).—Up to 1908 the policy adopted by the national Albanian leaders may be summarized as follows:—(1) To preserve the Ottoman Empire until such time as the Albanian national ideal, surreptitiously propagated by the various national societies resident abroad, had entered into the consciousness of the Albanian people as a whole (a process necessarily slow where 99% of the population was illiterate and in the face of the opposition of both 'Abdul Hamid and the Greek Patriarchate)—lest a premature disruption of Turkey might bring about the dismemberment of Albania herself at the hands of her Christian neighbours; (2) to press in the meantime by constitutional means for an autonomous administration of Albania.

Prominent among those in favour of these Fabian tactics were Ferid Pasha Vlora, the Sultan's trusted grand vizier, and his cousin Ismael Kemal. The keen appreciation by these statesmen of their country's predicament was amply proved by subsequent events. These events, however, they were unable to control. In July 1908 the Young Turk revolution became imminent. The Albanian mountain chiefs, throwing in their lot with the revolutionary movement, took the lead by telegraphing to the Sultan to demand the revival of the constitution of 1878. A few days later Maj. Enver Bey and the Committee of Union and Progress proclaimed the constitution at various places in Macedonia, and the II. and III. Army Corps threatened to march upon Constantinople. On July 24 the Sultan bowed to the inevitable. Six months later he was deposed after his attempt at counter-revolution had failed—an attempt undertaken with the aid of his Albanian bodyguard and with the

connivance of the Liberal union, headed by Ismael Kemal, who had already realized that the aims of the committee were little more liberal than the old régime's. The privilege of informing him of this decision of Parliament was reserved for another Albanian, Essad Pasha.

The Albanians had at first hailed the Turkish revolution with enthusiasm. It seemed to promise the fulfilment of their most cherished aspirations: autonomy and the introduction of means of education in the national tongue. Albanians had never been slow to avail themselves of any opportunity of educating themselves on national lines, as is proved by the phenomenal progress in education that had been made within Albania itself during the years 1870–86, when the establishment of Albanian schools was tolerated, as well as in the Albanian colonies abroad. The names of men like the brothers Sami and Naim Frasheri, the first a lexicographer and historian, the second a poet; of Wassa Pasha, founder of the society for the publication of Albanian books in Constantinople in 1879; and of Prenk Dochi, who became Abbot of the Mirditi in 1888, should especially be remembered in connexion with the obscure but heroic efforts on the part of patriotic Albanians to educate their countrymen prior to the revolution of 1908.

A "Bessa" (pledge of honour) was taken by the mountain tribesmen to suspend all existing blood feuds in honour of the auspicious occasion. It soon became evident, however, that not only was nothing to be hoped for from the Young Turks but that the triumph of the revolutionary movement was to prove a more formidable menace to the cause of Albanian nationality than the obscurantist tyranny of the Sultan. The Committee of Union and Progress had no sooner obtained a settlement of the international questions arising out of the annexation of Bosnia-Herzegovina and of Eastern Rumelia by Austria-Hungary and Bulgaria respectively, than they actively set to work to achieve their plan of Ottomanizing the subject races of Turkey. The Albanian schools, which had recently been able to open their doors through private contributions, were again closed, the Albanian newspapers were again forced to migrate to foreign lands, and the national movement was stopped. In the face of violent protests a decree was issued that the Albanian language might be taught with the Turkish instead of Latin characters and a number of school-books were actually published in this manner. But the Albanians saw through the device and would have none of it. Heaps of the books were burned in the market-places.

Insurrection of 1911–2.—At the same time an insurrectionary movement broke out among the Moslem tribes in the north, headed by 'Isa Boletin, a natural leader of rare prowess who rallied the mountain tribesmen disaffected by the attempt of the Young Turks to levy taxation from which hitherto they had been exempt. The Turks, however, retaliated by ruthless efforts to disarm the population. Whole villages were destroyed and —what the proud clansmen would less easily forgive—their chiefs were publicly flogged. In 1911 the insurrection assumed larger dimensions. While the Moslem tribes kept quiet the Roman Catholic Malzia and Mathe tribes, instigated by the Montenegrins, formed armed bands, and in the spring attacked with success the Turkish outposts on the Montenegrin frontier. In April Torgut Shevket Pasha tried to suppress the movement with a large army, but notwithstanding the superiority of his forces, met with several reverses. In May Russia warned the Ottoman Government not to extend hostilities against Montenegro, who was harbouring a large number of the refugees. In June Mirdita joined the rebels, proclaiming her own autonomy and setting up a provisional government. In the same month there was a great meeting of rebel chiefs, who drew up a statement of their grievances and a list of their demands under 12 headings, of which the most important were the recognition of Albanian nationality and the use of the Albanian language in the schools and in all local administration.

Balkan War, 1912–3.—The Turks attempted to bribe and cajole Mgr. Sereggi, Archbishop of Scutari, a brave and honest patriot, to intervene. He protested that he had not the authority; nor was it his business. The inevitable result was that the following year, when the Turks were fully engaged in the war with Italy, the insurrection broke out afresh. The Albanians of Kossovo joined in the revolt, seized Pristina, and published a manifesto demanding a dissolution of Parliament and the holding of fresh and fairly conducted elections. Southern Albania joined the insurgents and success followed success. In May Uskub was occupied. In view of trouble brewing elsewhere the Turks had no alternative but to give in. By the terms of the cessation of hostilities, Albania was recognized by the Turkish Government as an autonomous administrative province comprising the four Albanian vilayets of Scutari, Kossovo, Yannina and Monastir, and more or less the same conditions already granted on paper were definitely ratified. Of all these concessions, however, by far the most important was the recognition on the part of Turkey that Albania extended to the four vilayets. This was the first official delimitation of the frontiers of Albania.

The success of the Albanians was, no doubt, a considerable factor contributing to the outbreak of hostilities between Turkey and the Balkan League in the autumn of 1912. The latter were encouraged by the reverses sustained by the Turkish army under their German leaders, and the grant of autonomy, were it allowed time to consolidate the national organization of the country, threatened to jeopardize the aims of the league, which envisaged the partition of Albania. The latter suffered from possessing no effective central authority. Accordingly, when the war broke out in Oct., the Albanians were divided as to the right policy to pursue. The Roman Catholic Maltsors joined the Montenegrins; the Kossovo Albanians fought half-heartedly on the side of the Turks; the rest of the Albanians remained neutral. The Maltsors, moreover, withdrew from the struggle before the end of the hostilities, being enraged at the cruel treatment by the Montenegrins of their Moslem neighbours. In fact, apart from the defence of the two fortresses of Yannina and Scutari, the safety of which was considered a vital point to the life of Albania, the Albanians practically left the Turks alone in their struggles.

During Nov. the greater part of northern and central Albania was invaded by the Serbians and Montenegrins, and the greater part of Epirus was in the possession of the Greeks. Albania seemed lost. But at this juncture the prompt action of Ismael Kemal partially saved the situation. After consulting with the Governments of Austria-Hungary and Italy, the two Powers interested in the maintenance of an integral Albania, he landed in the nick of time at Durazzo before the capture of that town by the Serbians. Thence he proceeded on horseback to Valona and summoned there an assembly of representative notables from all parts of Albania. On Nov. 28 1912 the national flag, the black double-headed eagle of Scanderbeg on a blood-red ground, was hoisted over the town and a formal proclamation of independence was issued together with a declaration of neutrality. This act gave the Austro-Hungarian and Italian Governments the necessary lead for their diplomatic intervention. But owing to the championship of Russia of the allies' cause, the only immediate result of this was the menace of a general European conflict. It was left to England, the only Power with any pretensions to impartiality, to lend her best offices to bring about an accommodation, and it was owing to the untiring efforts of Sir Edward (afterwards Lord) Grey that eventually a peaceful but by no means altogether satisfactory compromise was arrived at. A conference of ambassadors was assembled in London, and on Dec. 20 the principle of Albanian autonomy was admitted. The allies agreed to leave to the Great Powers the task of delimitating the frontiers and defining the status of Albania and a clause was drafted to this effect for insertion in the Treaty of London (May 1913) between the allies and Turkey. On April 7 1913 Sir Edward Grey made the following statement to the House of Commons:—"The agreement between the Powers respecting the frontiers of Albania was reached after a long and laborious diplomatic effort. It was decided that the littoral and Scutari should be Albanian,

estimated reserves of coal in the surveyed fields of Alaska were 19,590,000,000 tons, of which 12,610,000,000 tons were lignite. Oil seepages were found at four localities on the Pacific seaboard: namely, Yakataga, Katalla, Iniskin Bay and Cold Bay, and also at several places near the N. Arctic coast. Only at Katalla, 60 m. E. of Cordova, was there any considerable drilling; here there was some oil production from the only petroleum claim to which patent had been granted. The withdrawal in 1911 of oil lands from entry stopped all development. In 1919 an oil leasing law was passed, and the development of producing fields was expected to follow. The total Alaska oil production to the close of 1920 was 60,000 barrels. Meanwhile, the Territory was consuming about 5,000,000 barrels of imported petroleum products annually. The only considerable production of tin in North America was from the York district on Bering Sea, near Cape Prince of Wales. A total of 1,000 tons of metallic tin had been mined since operations began in 1900. Alaska had produced in all about 9,800,000 oz. of silver and 5,000 tons of lead. This had practically all been won from gold and copper ores, for no large deposits of silver and lead had been developed. The mining of platinum and related minerals began in 1916, since which time about 1,500 oz. of those minerals had been produced. Demands of the World War led to the mining of some antimony, tungsten and chromite ores, but with the decreased value of these metals after the peace these operations ceased. Quicksilver mining had been carried on in a small way for many years. There were in south-eastern Alaska extensive deposits of high-grade marble which had been quarried on a large scale.

Fisheries.—The total value of fish products which had been marketed (1867–1919) was $418,000,000. In 1919 the output of the fisheries brought in $50,282,000, of which $45,000,000 was for salmon. Two small salmon canneries were built in Alaska in 1879; by 1919 the number had grown to 134. The fishing industry in 1919 employed 28,500 persons, of which 3,875 were Indians. Ninety per cent were engaged in salmon canning. The canneries can be operated during only from two to four months of the year, and much the larger part of the labour is imported. About 90% of the salmon caught in Alaskan waters are canned. In 1911 a total of 44,000,000 salmon were caught in Alaskan waters. This was increased in 1918 to 101,500,000, but fell to 58,000,000 in 1919. The enormous catch of 1918 was due to the stimulus of the war demands, and was undoubtedly in excess of the number that can be taken without permanently impairing the industry. In the early days of the salmon-fishing there were no restrictions, but, beginning in 1902, laws were passed to regulate the fisheries. The latest law (1906) was a great improvement on those preceding, but is by no means adequate. As an additional precautionary measure, hatcheries were established. There were five of these operated in 1919, at which were hatched and liberated 95,580,000 young salmon. In theory this should suffice to provide for the annual catch, but in practice only a small part survive as adult fish. The importance to the nation of conserving the Alaska salmon fisheries is indicated by the fact that in 1919 a total of 133,680,000 lb. of salmon were shipped from the Territory. The halibut fisheries are being depleted even more rapidly than the salmon. About 14,000,000 lb. are caught in Alaska and adjacent waters each year. The industry employs about 900 men and 90 small vessels. The halibut is all shipped fresh; much of it to the E. coast markets, and some to Europe. The number of cod on the Alaska cod banks is enormous, but as yet they have been little exploited. The total annual catch is between 10 and 11 million pounds, and the number of men employed is only a few hundred. Herring are found in great abundance as far north as Bering Strait. Whale-fishing along the coast, once a very important industry, is now limited to a few shore stations, where the catch is chiefly utilized for making fertilizer. There has been some canning of crabs and clams. The Alaska crab, which is the same species as that found in the Pacific waters farther south, is especially delicious.

Forest Products.—The national forests of Alaska include all the best timber lands (total area 20,000,000 acres). These are estimated to contain 77,000,000,000 ft. (B.M.) of timber suitable for lumber and pulp. Up to 1921 these forests had been used almost solely for local use, though some spruce had been exported for the manufacture of aeroplanes and other articles which require great toughness of fibre. It was officially estimated that these forests were capable of furnishing 2,000,000 cords of pulp-wood annually. A pulp-wood industry was developed in south-eastern Alaska in 1920.

Agriculture.—Alaska contains extensive farm lands adapted to raising the hardier varieties of wheat, oats, barley, rye, potatoes and other hardy vegetables, and forage crops. The most promising agricultural fields were in the Tanana and Susitna valleys, both tributary to the Government railroad. Tests in this region showed that sugar beets can be matured that contain a high percentage of sugar. Extensive areas of agricultural land are also found in other parts of the Yukon basin, and smaller patches here and there in the Pacific coastal region. The best-developed farming area was in the neighbourhood of Fairbanks, where about 2,000 acres of land were under cultivation. Here a hardy variety of wheat was matured during five successive years, and part of the flour for local consumption was made in a small mill. There is an abundance of good grazing land in the interior, but the period of winter feeding is about eight months. Up to 1921 the only cattle introduced were small herds used for dairying. The Government recently began the experiment of introducing yaks into this region. The domesticated reindeer herds numbered in 1920 92,933 valued at $2,238,562 against 22,107 in 1910. This was the natural increase from the original 1,200 imported by the Government between 1892 and 1902. About 70% of the herd was owned by the Eskimo, for whose support the animals were first imported. Some reindeer meat had been exported, and the amount promised to increase.

Fur Industry.—Between 1867 and 1920 Alaska produced furs to the value of $90,400,000, of which $53,000,000 represents seal skins taken on the Pribilof Is. in Bering Sea. Up to 1910 the Government leased the seal-catching privileges on the Pribilof Is. to private corporations, which killed 2,320,028 seal and paid the Government $9,474,000 in royalties. The land killing of seal was properly restricted, but pelagic sealing by vessels of various nationalities destroyed an additional 976,000 seal. Pelagic sealing, being on the high seas, could not be controlled by the American Government; therefore a treaty was signed in 1911 between the United States, Great Britain, Russia and Japan, abolishing it and providing that the United States was to pay to Great Britain and Japan each 15% of the catch made on the islands. Since 1910 killing has been prohibited on the Pribilof Is. except by Federal agents. Thanks to these provisions, the seal herd has increased from 215,000 in 1912 to 524,000 in 1919. In the latter year the Government sold 19,157 dressed seal skins, for which $1,501,600 was received. The value of all furs shipped in 1919, besides the seal, was $1,500,000, of which over half is to be credited to the fox. Fur farming increased rapidly during the World War owing chiefly to the high value of furs. Most of the successful farms are on small islands, and practically all are devoted to the raising of foxes, though attempts have been made to raise both mink and marten.

ALBANIA (*see* 1.481).—Up to 1908 the policy adopted by the national Albanian leaders may be summarized as follows:—(1) To preserve the Ottoman Empire until such time as the Albanian national ideal, surreptitiously propagated by the various national societies resident abroad, had entered into the consciousness of the Albanian people as a whole (a process necessarily slow where 99% of the population was illiterate and in the face of the opposition of both 'Abdul Hamid and the Greek Patriarchate)—lest a premature disruption of Turkey might bring about the dismemberment of Albania herself at the hands of her Christian neighbours; (2) to press in the meantime by constitutional means for an autonomous administration of Albania.

Prominent among those in favour of these Fabian tactics were Ferid Pasha Vlora, the Sultan's trusted grand vizier, and his cousin Ismael Kemal. The keen appreciation by these statesmen of their country's predicament was amply proved by subsequent events. These events, however, they were unable to control. In July 1908 the Young Turk revolution became imminent. The Albanian mountain chiefs, throwing in their lot with the revolutionary movement, took the lead by telegraphing to the Sultan to demand the revival of the constitution of 1878. A few days later Maj. Enver Bey and the Committee of Union and Progress proclaimed the constitution at various places in Macedonia, and the II. and III. Army Corps threatened to march upon Constantinople. On July 24 the Sultan bowed to the inevitable. Six months later he was deposed after his attempt at counter-revolution had failed—an attempt undertaken with the aid of his Albanian bodyguard and with the

In Nov. 1916 the Italians had occupied Valona. In the autumn of 1915 the Austro-Hungarians, after overrunning Serbia, occupied northern and central Albania. Essad retired to Salonika where he continued to pose for some considerable time as the true Albanian representative until he became finally discredited. Many Albanians adhered to the cause of the central empires. This was not unnatural since a victory for Germany would in all probability have given Albania an autonomous, if not an independent, government within wider frontiers than she could ever otherwise hope for. Under Bairam Tsuri, an unsurpassed *guerillero*, Albanian bands harassed the Allied lines of communication which ran from Santi Quaranta to Koritsa and Salonika.

On June 3 1917 Italy proclaimed the independence of all Albania under Italian protection. This proclamation was subsequently explained as not denoting a "protectorate," but it could hardly be interpreted as anything but a formal repudiation of the articles of the Pact of London. The French, who had occupied the Ersek-Koritsa road, replied by proclaiming the republic of Koritsa. After three months the republic was abolished, but the district remained under French rule until May 1918, when it was handed over to the Albanians. Then came the retreat of the Austrians in the autumn of that year. Thus the greater part of Albania fell under the occupation of Italy. An inter-Allied contingent on the other hand occupied Scutari, while Serbian troops seized Mt. Tarabosh and advanced their line considerably west of the 1913 frontier.

In March 1920 the inter-Allied command at Scutari handed over their powers to a small Italian contingent, which in May 1921 still remained in the town as representing the Allied and Associated Powers pending the formal recognition of the Albanian State and the confirmation of its frontiers.

Meantime important events had occurred which finally paved the way for the reëstablishment of Albanian independence. The Italians permitted the formation of a new national provisional government within their area of occupation, and Albania's case was duly presented at the Peace Conference in 1919. Her representatives included Turchan Pasha, who had acted as Prince William's prime minister; Dr. Tourtuli of Koritsa, the eminent specialist in tropical diseases; Mgr. Bumci, Bishop of Alessio; and Mehmet Bey Konitza, later Minister of Foreign Affairs and representative of the Vatra, an important national society of Albanians resident in America which had risen during the last ten years under the able organization of Faik Konitza and Mgr. Fa Noli, to take a leading part in the cause of Albanian independence. The general complications of the Adriatic question, however, prevented the Albanian case being concluded. President Wilson vetoed a proposal to partition the country. The Italians at the same time lost their initial popularity. It was generally understood that they had provisionally accepted a mandate for Albania. There were evident signs in any case of an intention on their part to remain in permanent occupation. They treated the local authorities with scant courtesy and seriously hampered the independent working of the central Government. The latter were also keenly aware that a permanent Italian occupation inevitably entailed the admission of at least part of the Greek and Serbian claims to their territory.

It was in these circumstances that fighting broke out between Albanian irregulars and the Italian troops, which had been greatly reduced in numbers and were suffering badly from malaria. The Italians accordingly concentrated within certain strategical areas, and thus enabled a new and more representative Albanian Government to be formed in Feb. 1920, first at Lyusna and then at Tirana, under the presidency of Suleiman Bey Delvina. Four constitutional regents were simultaneously appointed, namely, Mgr. Bumci, Dr. Tourtuli, Abdi Toptani and Akif Pasha—*i.e.* two Mussulmans, one Catholic and one Orthodox. Later in the year the Albanians under Bairam Tsuri again attacked the Italians, capturing many important positions and pressing them hard within the Valona area itself. Italy was in no mood for further wars. The economic and social condition of the country forbade any hope the Italian Nationalist parties still entertained of imposing by force of arms Italian rule in Albania. Moreover, Giolitti had assumed power with a large Liberal majority behind him, and he had made up his mind to tackle the Albanian question otherwise. The result was an agreement signed on Aug. 2 1920, by which Albania's independence was completely recognized by Italy and the evacuation of the country by the Italian troops assured.

The Serbs, who had attempted to profit by the occasion, had advanced on Tirana, but after some severe fighting had been driven back to their original positions. Yet in spite of these successes the Government of Suleiman Bey fell in the autumn. It was replaced by a Ministry under Illias Vrioni, pending the election due to take place in the following spring of a new Chamber, Mgr. Fa Noli was appointed Albanian representative at Geneva and in Jan. 1921 Albania was formally admitted to full membership of the League of Nations, all the parties (Italy, Serbia and Greece), at one time interested in her dismemberment, recording their vote in favour of the motion.

ALBERT I., King of the Belgians (1875–), was born at Brussels April 8 1875, the younger son of Philip, Count of Flanders (1837–1905), brother of Leopold II., by his marriage with Princess Marie of Hohenzollern. The other children of this marriage were: Baldwin (b. 1869), Henriette, afterwards Duchess of Vendôme (b. 1870), a daughter who died in infancy, and Josephine, afterwards Princess Charles of Hohenzollern (b. 1872). The premature death of Prince Leopold, only son of Leopold II., on June 22 1869, made Prince Baldwin heir presumptive to the Belgian crown, but on the death of the young prince on Jan. 23 1891, Prince Albert became next in the line of succession. He was carefully educated, and showed a marked taste for engineering and mechanics, studying both naval and aerial construction. He received his training in military matters at the École Militaire under Gen. Jungblut, and also became a thorough all-round sportsman, taking much interest in mountaineering and later in aviation. On Oct. 2 1900 he was married at Munich to Princess Elisabeth (b. July 25 1876, at Possenhofen), second daughter of Duke Charles Theodore of Bavaria. Three children were born of this marriage: Leopold, Duke of Brabant (b. Nov. 3 1901), Charles, Count of Flanders (b. Oct. 10 1903), and Marie José (b. Aug. 4 1906).

Prince Albert also travelled widely, paying a visit to America in 1898, and in 1908 visiting England in order to study naval construction. In April 1909 he went to the Belgian Congo in order to acquaint himself with colonial conditions, returning in Aug. of the same year.

On the death of Leopold II. on Dec. 1 1909 Prince Albert took the oath of fidelity to the Belgian constitution and became king under the name of Albert I. He occupied himself more especially with the organization of the army and in May 1913 gave his assent to the law which was designed to secure for Belgium an army of 350,000 men. He also interested himself in various social and legal reforms, while his scientific tastes did not prevent him from becoming a friend of art and

estimated reserves of coal in the surveyed fields of Alaska were 19,590,000,000 tons, of which 12,610,000,000 tons were lignite. Oil seepages were found at four localities on the Pacific seaboard: namely, Yakataga, Katalla, Iniskin Bay and Cold Bay, and also at several places near the N. Arctic coast. Only at Katalla, 60 m. E. of Cordova, was there any considerable drilling; here there was some oil production from the only petroleum claim to which patent had been granted. The withdrawal in 1911 of oil lands from entry stopped all development. In 1919 an oil leasing law was passed, and the development of producing fields was expected to follow. The total Alaska oil production to the close of 1920 was 60,000 barrels. Meanwhile, the Territory was consuming about 5,000,000 barrels of imported petroleum products annually. The only considerable production of tin in North America was from the York district on Bering Sea, near Cape Prince of Wales. A total of 1,000 tons of metallic tin had been mined since operations began in 1900. Alaska had produced in all about 9,800,000 oz. of silver and 5,000 tons of lead. This had practically all been won from gold and copper ores, for no large deposits of silver and lead had been developed. The mining of platinum and related minerals began in 1916, since which time about 1,500 oz. of those minerals had been produced. Demands of the World War led to the mining of some antimony, tungsten and chromite ores, but with the decreased value of these metals after the peace these operations ceased. Quicksilver mining had been carried on in a small way for many years. There were in south-eastern Alaska extensive deposits of high-grade marble which had been quarried on a large scale.

Fisheries.—The total value of fish products which had been marketed (1867–1919) was $418,000,000. In 1919 the output of the fisheries brought in $50,282,000, of which $45,000,000 was for salmon. Two small salmon canneries were built in Alaska in 1879; by 1919 the number had grown to 134. The fishing industry in 1919 employed 28,500 persons, of which 3,875 were Indians. Ninety per cent were engaged in salmon canning. The canneries can be operated during only from two to four months of the year, and much the larger part of the labour is imported. About 90% of the salmon caught in Alaskan waters are canned. In 1911 a total of 44,000,000 salmon were caught in Alaskan waters. This was increased in 1918 to 101,500,000, but fell to 58,000,000 in 1919. The enormous catch of 1918 was due to the stimulus of the war demands, and was undoubtedly in excess of the number that can be taken without permanently impairing the industry. In the early days of the salmon-fishing there were no restrictions, but, beginning in 1902, laws were passed to regulate the fisheries. The latest law (1906) was a great improvement on those preceding, but is by no means adequate. As an additional precautionary measure, hatcheries were established. There were five of these operated in 1919, at which were hatched and liberated 95,580,000 young salmon. In theory this should suffice to provide for the annual catch, but in practice only a small part survive as adult fish. The importance to the nation of conserving the Alaska salmon fisheries is indicated by the fact that in 1919 a total of 133,680,000 lb. of salmon were shipped from the Territory. The halibut fisheries are being depleted even more rapidly than the salmon. About 14,000,000 lb. are caught in Alaska and adjacent waters each year. The industry employs about 900 men and 90 small vessels. The halibut is all shipped fresh; much of it to the E. coast markets, and some to Europe. The number of cod on the Alaska cod banks is enormous, but as yet they have been little exploited. The total annual catch is between 10 and 11 million pounds, and the number of men employed is only a few hundred. Herring are found in great abundance as far north as Bering Strait. Whale-fishing along the coast, once a very important industry, is now limited to a few shore stations, where the catch is chiefly utilized for making fertilizer. There has been some canning of crabs and clams. The Alaska crab, which is the same species as that found in the Pacific waters farther south, is especially delicious.

Forest Products.—The national forests of Alaska include all the best timber lands (total area 20,000,000 acres). These are estimated to contain 77,000,000,000 ft. (B.M.) of timber suitable for lumber and pulp. Up to 1921 these forests had been used almost solely for local use, though some spruce had been exported for the manufacture of aeroplanes and other articles which require great toughness of fibre. It was officially estimated that these forests were capable of furnishing 2,000,000 cords of pulp-wood annually. A pulp-wood industry was developed in south-eastern Alaska in 1920.

Agriculture.—Alaska contains extensive farm lands adapted to raising the hardier varieties of wheat, oats, barley, rye, potatoes and other hardy vegetables, and forage crops. The most promising agricultural fields were in the Tanana and Susitna valleys, both tributary to the Government railroad. Tests in this region showed that sugar beets can be matured that contain a high percentage of sugar. Extensive areas of agricultural land are also found in other parts of the Yukon basin, and smaller patches here and there in the Pacific coastal region. The best-developed farming area was in the neighbourhood of Fairbanks, where about 2,000 acres of land were under cultivation. Here a hardy variety of wheat was matured during five successive years, and part of the flour for local consumption was made in a small mill. There is an abundance of good grazing land in the interior, but the period of winter feeding is about eight months. Up to 1921 the only cattle introduced were small herds used for dairying. The Government recently began the experiment of introducing yaks into this region. The domesticated reindeer herds numbered in 1920 92,933 valued at $2,238,562 against 22,107 in 1910. This was the natural increase from the original 1,200 imported by the Government between 1892 and 1902. About 70% of the herd was owned by the Eskimo, for whose support the animals were first imported. Some reindeer meat had been exported, and the amount promised to increase.

Fur Industry.—Between 1867 and 1920 Alaska produced furs to the value of $90,400,000, of which $53,000,000 represents seal skins taken on the Pribilof Is. in Bering Sea. Up to 1910 the Government leased the seal-catching privileges on the Pribilof Is. to private corporations, which killed 2,320,028 seal and paid the Government $9,474,000 in royalties. The land killing of seal was properly restricted, but pelagic sealing by vessels of various nationalities destroyed an additional 976,000 seal. Pelagic sealing, being on the high seas, could not be controlled by the American Government; therefore a treaty was signed in 1911 between the United States, Great Britain, Russia and Japan, abolishing it and providing that the United States was to pay to Great Britain and Japan each 15% of the catch made on the islands. Since 1910 killing has been prohibited on the Pribilof Is. except by Federal agents. Thanks to these provisions, the seal herd has increased from 215,000 in 1912 to 524,000 in 1919. In the latter year the Government sold 19,157 dressed seal skins, for which $1,501,600 was received. The value of all furs shipped in 1919, besides the seal, was $1,500,000, of which over half is to be credited to the fox. Fur farming increased rapidly during the World War owing chiefly to the high value of furs. Most of the successful farms are on small islands, and practically all are devoted to the raising of foxes, though attempts have been made to raise both mink and marten.

ALBANIA (*see* 1.481).—Up to 1908 the policy adopted by the national Albanian leaders may be summarized as follows:—(1) To preserve the Ottoman Empire until such time as the Albanian national ideal, surreptitiously propagated by the various national societies resident abroad, had entered into the consciousness of the Albanian people as a whole (a process necessarily slow where 99% of the population was illiterate and in the face of the opposition of both 'Abdul Hamid and the Greek Patriarchate)—lest a premature disruption of Turkey might bring about the dismemberment of Albania herself at the hands of her Christian neighbours; (2) to press in the meantime by constitutional means for an autonomous administration of Albania.

Prominent among those in favour of these Fabian tactics were Ferid Pasha Vlora, the Sultan's trusted grand vizier, and his cousin Ismael Kemal. The keen appreciation by these statesmen of their country's predicament was amply proved by subsequent events. These events, however, they were unable to control. In July 1908 the Young Turk revolution became imminent. The Albanian mountain chiefs, throwing in their lot with the revolutionary movement, took the lead by telegraphing to the Sultan to demand the revival of the constitution of 1878. A few days later Maj. Enver Bey and the Committee of Union and Progress proclaimed the constitution at various places in Macedonia, and the II. and III. Army Corps threatened to march upon Constantinople. On July 24 the Sultan bowed to the inevitable. Six months later he was deposed after his attempt at counter-revolution had failed—an attempt undertaken with the aid of his Albanian bodyguard and with the

credit for developing the irrigation system belongs to the C.P.R. company, whose scheme covers about 1,000,000 ac. in the area around Calgary, where a heavy thick black loam of from 4 to 8 in. in depth, with a subsoil of chocolate-coloured clay, constitutes a region well adapted to diversified farming. The source of water supply is the Bow river. The soils of northern Alberta are for the most part characterized by high percentages of organic matter and nitrogen, and are superior to those in the southero part of the province. Southern Alberta is of a true prairie character. Northern Alberta is to a large extent wooded, enjoying a greater rainfall, and is naturally better adapted for mixed farming. Alberta is adapted in varying degrees to the growing of small grains, including wheat, oats, barley, rye, peas and flax, which can all be grown successfully and profitably from Medicine Hat to Fort Vermilion. In 1918 the wheat production of the province was 23,751,514 bushels. The oat production in the same year was 60,322,717 bushels. Ninety-six different varieties of native grasses have been identified in Alberta and of these not less than 46 make excellent hay whilst there are at least 94 varieties of sedges and rushes, many of which make good hay and all make splendid pasture during the spring and early summer. The true grasses occur on the uplands, and grow with wild pea, vine and vetches. Native hay, western rye grass, blue grass, buffalo grass and bunch grass abound in luxuriaot stretches. These extend through the passes into the mountains and fill the valleys with a luxuriant growth of luscious plants for cattle. Such conditions constitute Alberta as a whole an ideal live-stock country.

There is still however much land devoted to ranching in the foothill country W. of the Calgary-Edmonton railway. This consists of rolling land with good grasses on the knolls, excellent live springs and running water and plenty of natural shelter. Beef is also raised on proprietary ranches of the prairie country, on leased lands in the eastern and central parts, and on the edges of the settled parts of the Peace River country. The superiority of Alberta ranch beef is accounted for by the superiority of the ranch grasses, the climate and the use of good beef bulls. The ranch cattlemen have olways bought the best bulls obtainable of the Shorthorn, Hereford and Aberdeen-Angus breeds. The demand for pure bred stock is very active, and the establishment of pure bred beef herds has been going on rapidly.

Building material and fuel in almost unlimited amounts are procurahle in the forests of northern Alberta, the timber lands extending hundreds of miles on the N. side of the Saskatchewan river. Poplar, birch, pine, white and black spruce, douglas fir and larch are among the commercial trees in these forests belts. South of the North Saskatchewan the timber is principally cottonwood and poplar. In the foothills aod river valleys considerable spruce is found. Saw-mills have been established at various points. The output for 1918 was valued at $473,694 and represented a capital investment of $1,500,000. Over 26,000 sq. m. of territory have been set aside as forest reserves and Dominion parks.

In the mountain section of the province large oreas have heen set apart by the Dominion Government for forest ond game preservation and for recreation. Good roads have been built through these reservations and they are carefully guarded against both fire and illicit hunting. Rocky Mountain park, with Banff and Lake Louise as the chief centres, contains 3,800 sq. m., while Jasper park on the Grand Trunk Pacific is about 600 sq. m. larger. There is also a small reservation at Waterton lake. The Dominion Government uoder the direction of the Commissioner of Parks has taken steps not only to prevent the total extinction of the buffalo hut has established parks for the protection and breeding of these and other native animals. The largest of these parks, 150 sq. m. in extent, is at Wainwright, where nearly 3,800 of the former monarchs of the plains are living secure from slaughter.

Fishing and Fur Trading.—The immense lakes of northern Alberta are heavily stocked with fish, the most important being whitefish and pike. Trout and pickerel are also abundant. The catch is used largely for local consumption but there is some export, and prospects of future large developments. Fur trading is still an important industry in the northern section of the province of which Edmonton is the centre. Otter, mink, ermine, wolverine, marten, badger, squirrel, bear, fox, wolf and lynx all enter into the production. Three companies, in additlon to many private traders, are engaged in the traffic.

Coal.—Vast beds of coal are found extending for hundreds of miles a short distance below the surface of the plains. It may olmost be said that the whole of the province is underlaid with coal, and it is estimated that 16% of the coal deposits of the world occur in Alberta. Anthracite is only found in ooe small pocket near Banff, which was opened some years ago but has not been operated for some time. Every other grade of coal ranging from the best bituminous to ordinary brown coal or lignite is found. Broadly, the better grades are found next to the Rockies where the carboniferous strata have been subject to the greatest pressure, the quality falling off as we proceed eastward. Owing to the general movement at the time of the formation of the mountains the strata of coal have been very much broken up. On this account coal-mining in Alberta, although the seams lie very close to the surface, is of a very difficult nature: the mines must be closely timbered right up to the working face. Over 5,000,000 tons are mined annually, to a value of over $10,000,000, the mines being equipped for an output of 15,000,000 tons.

Natural gas under heavy pressure is found at many points throughout the province and is extensively used for power, fuel and light. In the Athabasca region and near the B.C. boundary there are decided indications of petroleum and a limited amount of coal oil is now being refined. The tar sands of northern Alberta are a striking feature in the geological resources of the province. It is estimated that the area of tar sands amounts to at least 1,000 sq. m. which with an average thickness of 150 ft. would give 28·4 cub. m. or 4,700,000,000 tons of bitumen or 6·5 cub. m. of tar. The sands of the North Saskatchewan river have for years yielded some gold. The output of clay and stone in the province is valued at over $1,000,000 aonually. There are also large salt deposits in the northern part of Alberta. The annual mineral production of the province exceeds $15,000,000.

Manufactures.—There are large and prosperous manufacturing establishments which supply local needs and engage in export business. Large abattoirs and meat-packing plants are located at Calgary and Edmonton. Throughout the province there are flour and sawmills, brick-yards and tile works, cement works, stone quarries and other monufacturing enterprises.

Communications.—In former days the North Saskatchewan was chiefly depended on for carrying freight by steamboats, but transport has been largely transferred to the railways which extend throughout the province in every direction. The main line of the C.P.R. sends a branch N. to Edmonton and another S. to Macleod. From the Edmonton branch there are two offshoots starting at Lacombe and Wetaskiwin. Other branches diverge from the main line at different points, extending into the new districts. The great passes of the Yellowhead and Peace river have also been made highways of traffic. The Canadian National railway lines connect Edmonton with Winnipeg and Port Arthur on the E. and with Vancouver and Prince Rupert on the W., the latter going through the Yellowhead pass. The same system has also a line to Calgary from the E. as well as extensions westward into the coal fields. Two other railways, built principally for colonization purposes, open up vast stretches of new country and are proving of inestimable value in connexion with the Peace river district and the northern country. These are the Edmonton and Great Waterways, and the Edmonton, Dunvegan and B.C. railway; the latter has been taken over by the C.P.R. from the Government of Alberta. Sternwheel steamers ply on the rivers and lakes of the northern section during the summer months.

Alberta was the first province of the Dominion to own and operate a telephone system of its own. In the year 1911 the province owned and operated 3,500 m. of long-distance lines and about 2,500 m. of rural or farmers' lines, and this service has been annually extended. (W. L. G.*)

ALCOCK, SIR JOHN (1892–1919), British airman, was born in Manchester Nov. 6 1892. He received his technical training there at the Empress motor works and obtained the flying certificate of the R.A.C. in 1912. He joined the R.N.A.S. at the beginning of the World War, being appointed instructor at Eastchurch and, later, chief instructor to the aeronautic squadron. He then went to the Turkish front, winning the D.S.O. for an attack on three enemy seaplanes, and also establishing a record for long-distance bombing flights. He was taken prisoner by the Turks in 1917 and released after the Armistice. On June 15 1919 Alcock, as pilot, with Lt. A. W. Brown as observer, won the prize offered by the London *Daily Mail* for the first successful flight across the Atlantic. For this achievement both airmen were knighted. On Dec. 18 1919 Alcock was killed by the crashing of his aeroplane at Côte d'Evrard, north of Rouen, in France.

ALCOHOL (*see* 1.525).—Alcohol intended for potable purposes has always been subject to a heavy duty in all countries. In the United Kingdom the duty on alcohol was raised in 1920 from 30s. to 72s. 6d. a proof gallon. Owing to its prohibitive price, duty-paid alcohol cannot be used for the many purposes for which it is essential, quite apart from the production of light, heat and power. Its earliest employment in industry was as an illuminant, and dates back to the early part of the 19th century.

In 1853 exhaustive experiments were carried out in England with a view to ascertaining whether it would be possible so to treat alcohol as to allow it to be used industrially without, at the same time, any risk of the revenue being defrauded. These experiments resulted in the legislation of 1855, when the use of duty-free alcohol mixed with 10% by volume of wood naphtha, known as methylated spirits, was authorized for manufacturing purposes only. From 1861–91 methylated spirits prepared in this way were allowed to be sold by retail in Great Britain in small quantities for domestic purposes such as cleaning, heating

and lighting; but use in large quantities, or in manufacture, was only possible under special authority and under excise supervision. The Netherlands legalized the use of denatured alcohol in 1865; in 1872 France permitted its use under a special tax, and in Germany its employment was authorized in 1879, the other European countries following, Austria in 1888, Italy in 1889, Sweden in 1890, Norway in 1891, Switzerland in 1893, and Belgium in 1896. In the United States the tax on distilled spirits was repealed in 1817, but was reimposed at the outbreak of the Civil War in 1861, and it was not until 1907 that denatured alcohol became tax-free for general purposes. Alcohol was used in Germany for many years before the World War in increasing quantities as a source of heat, but its application for light and power started about 1887. In 1895, in order to bring down its price, a distillation tax was imposed, from which a refund was paid on alcohol used for other than beverage purposes. About this date the output of alcohol in Germany and its use in stationary internal-combustion engines increased rapidly. The chief source was the bounty-fed potato, and the industry was an agricultural one worked on coöperative principles.

The first competition in connexion with alcohol as a fuel for motor vehicles took place in France in 1901, followed in the next year by German investigations, but its employment for this purpose did not make much headway. The subject received little attention in the United Kingdom, owing to the relatively high cost of home-produced alcohol as compared with that of imported petrol; and the use of alcohol in England for generating mechanical power was neither contemplated nor provided for by the Legislature before 1920, when, as the result of the consideration of the position by the Government, following on a report by a Departmental Committee appointed towards the end of 1918, clauses were inserted in the Finance Act of 1920 legalizing the use of alcohol for power purposes.

Whilst alcohol is applied in motor engines in a similar manner to petrol, its vapour mixed with a proper proportion of air being drawn into the cylinder where it is compressed and ignited, it cannot be used with maximum efficiency by itself in engines such as are fitted to modern motors because it requires a higher degree of compression than petrol engines are usually designed to stand, and also because, unless special arrangements are made, a motor engine will not start readily from the cold with alcohol alone. For these reasons alcohol has not been used to any extent in petrol motors. Mixing with benzol and/or petrol, or with ether in varying proportions, enables it, however, to be employed successfully in them, until such time as engines specially designed for its use are available. In the event of its production being a commercial possibility it should, therefore, form a valuable addition to the liquid-fuel resources of the world (*see* FUEL).

In the appended table are given some comparative figures in connexion with commercial petrols and alcohol, taken from H. R. Ricardo's paper on "The Influence of Various Fuels on the Performance of Internal-Combustion Engines," published in 1921.

Alcohol and Petrol as Fuel.

Alcohol 95 Vol. %		0·815	442	11,130	0·705	32·5	0·565

Alcohol is produced by fermentation from vegetable substances containing starch or sugar, from fermentable sugars produced by the hydrolysis of cellulosic bodies, and synthetically from calcium carbide and from the ethylene contained in coal and coke-oven gases. These vegetable substances may be divided into foodstuffs and non-foodstuffs. If foodstuffs are to be employed it must be possible to grow them in excess of food requirements, and at a cost low enough to ensure that the price of the alcohol shall be about the same as that of other liquid fuels. Foodstuffs could not be grown in the United Kingdom at sufficiently low prices, nor in sufficient quantities, to produce alcohol commercially and on a large scale.

Investigations started in 1920 by the British Government, in connexion with the production of alcohol for power purposes, have shown, however, that there are large areas of suitable land in the British Empire where the cost of production would be comparatively low, and where it might be possible to grow vegetable substances in excess of food requirements, and in sufficient quantities to produce alcohol for local consumption to replace expensive petrol. It is in this direction, which is being actively followed up in the dominions and colonies, that the production of alcohol for use in internal-combustion engines is most likely to advance so far as the British Empire is concerned.

The use of non-foodstuffs, or cellulosic materials, such as grasses, reeds, straws, peat, waste wood, sawdust, etc., is not yet possible, for, although research work is in progress to discover a process that could be worked on a commercial basis in those regions where such materials exist in sufficient abundance, it has not so far led to any definite results. It would appear, however, that the production of power alcohol within the British Empire from waste materials, which can be collected and treated at low cost, offers the best chance of the solution of the problem of the supply to the United Kingdom of an alternative liquid fuel for internal-combustion engines.

Its manufacture from carbide is only possible where very cheap power is available, and its conversion from the quantities of ethylene removable from coal and coke-oven gas, even should a cheap process be worked out, is not likely to add very materially to the world's liquid-fuel supplies.

Whilst the use of alcohol for power purposes, mainly in connexion with stationary and agricultural engines, was common in Germany before the war, its employment in Europe and also in the United States for motor engines has not made much headway, nor was it apparent in 1921 that any active steps were being taken outside the British Empire to develop it for the purpose on any considerable scale. In France, where large stocks of alcohol were left over from the manufacture of explosives during the war, it was unable to compete with petrol as regards price, and was only being used in comparatively small quantities, and mixed with benzol. The German production of alcohol had fallen off very much since the war, and little if any was being used for motors, benzol being the fuel principally employed. The manufacture of alcohol from the sulphite lyes of the wood-pulp industry was contemplated, but carbide, although produced in increasing quantities, was not considered as a possible raw material owing to its greater importance as a source of the fertilizer cyanamide. An alcohol monopoly law was passed in July 1918. With cheap water-power Switzerland has considerable capacity for producing carbide and alcohol from it, but even in that country the ultimate cost of alcohol made in this way was so high that its production after the war had not paid. In Sweden, where wood pulp is made in enormous quantities, the manufacture of alcohol from the waste sulphite lyes is carried on, and it was estimated that in 1920 the probable capacity was in the neighbourhood of 8,000,000 gal.; the actual production, however, amounted to about 2,750,000 gal. only. Norway also produces sulphite lyes and alcohol from them on a smaller scale.

There are several distilleries in the United States devoted to the production of industrial alcohol, with an estimated capacity of about 90,000,000 gal.; in 1919 about 100,000,000 gal. were made, representing, however, only about 2½ % of the estimated United States liquid-fuel requirements for 1920. Some attention is also being given to the manufacture of alcohol for power purposes in Hawaii, Porto Rico and the Philippines; and in Cuba, from the molasses produced as a by-product in the sugar refineries. (F. L. N.)

ALDEN HENRY MILLS (1836–1919), American editor, descendant of John Alden, was born at Mt. Tabor, Vt., Nov. 11 1836. After graduating from Williams College (1857), under the *régime* of Mark Hopkins, he completed the course at the Andover Theological Seminary (1860); but he never took orders. He first contributed to the *Atlantic Monthly* two essays on "The Eleusinia" (1859–60), and then a paper on "Pericles and President Lincoln" (1863). These fruits of his classical studies show the influence of De Quincey, who was the subject of another essay in the *Atlantic* (1863). He delivered twelve lectures before the Lowell Institute in Boston, 1863–4, on "The Structure of Paganism." He was managing editor of *Harper's Weekly* from 1863 to 1869, and then became editor of *Harper's Magazine*, which position he held until his death in New York, Oct. 6 1919.

He was author of *God in His World* (1890); *A Study of Death* (1895) and *Magazine Writing and the New Literature* (1908).

ALDRICH, NELSON WILMARTH (1841–1915), American politician (*see* 1.536), died in New York April 16 1915. While chairman of the National Monetary Commission, he pro-

[1] The lower calorific value plus the latent heat of evaporation at constant volume.

posed, in 1911, far-reaching changes in the banking laws of the United States with a view to the creation of central reserves, a system afterwards adopted in the Federal Reserve banks. He retired from the U.S. Senate in 1911, after 30 years' service.

ALEXANDER, King of the Hellenes (1893–1920), second son of King Constantine and Queen Sophia, was born Aug. 1 1893, and ascended the throne of Greece, June 12 1917, on the dethronement of his father by the Anglo-French forces during the World War (*see* CONSTANTINE). He, not unnaturally, looked upon his position at first as a mere temporary arrangement. The Government itself was meanwhile in the responsible hands of Venizelos, who had the confidence of the Allies. But the defeat of Germany, and Venizelos's diplomatic triumphs at the Peace Conference, seemed to breathe a new spirit into the young King. From the day of his triumphal entry into Adrianople, he evidently took a more active personal interest in the prospect of being the ruler of Greater Greece. This change in his attitude was indeed so marked that his royal parents in exile in Switzerland were said to be greatly disconcerted; but it gave him an entirely new popularity among the people. His sudden death on Oct. 27 1920, by blood-poisoning from the bite of a pet monkey, put a sudden end to all such expectations, and it seriously disarranged Venizelos's plans. King Alexander was buried amid widespread demonstrations of popular grief; but a fortnight later, in the general election, the Venizelist party was defeated. It is practically certain that, could this election have been postponed for a few months and a suitable successor to the throne found, King Constantine would never have been able to return, as he did, to Greece. But postponement was impossible after Venizelos's pledges to the Greek people; and, in the absence of any other serious candidate for the Greek throne, the old sympathies for Constantine won the day.

In Nov. 1919 King Alexander had insisted, against the advice of Venizelos, on making a morganatic marriage with a beautiful young Athenian lady, Aspasia Mano; and after his death a daughter was born to her in Paris on March 25 1921.

ALEXANDER I., King of the Serbs, Croats and Slovenes (1888–), was born at Cettinje on Dec. 4 1888, the second son of Prince Peter Karagjorgjević (later King of Serbia), and of Zorka, third daughter of Prince Nicholas of Montenegro. His mother died in 1890, and during his early years he of course shared the exile of his father, who lived at Geneva. In 1899 he was sent to be educated at St. Petersburg, and in 1904 entered the *corps des pages* at the Tsar's court. It was not till 1909 (nearly six years after his father's election to the Serbian throne, in succession to the murdered King Alexander Obrenović) that the young prince came to reside permanently in Serbia. Soon after his return his elder brother, Prince George, was obliged to renounce the succession (March 1909), owing to his unbalanced temperament and various incidents that occurred during the Bosnian crisis; and Alexander was thereupon formally recognized as crown prince. On the outbreak of the Balkan War he assumed nominal command of the First Army, and won his spurs at the battle of Kumanovo, subsequently serving with distinction throughout the campaigns against Turkey and Bulgaria. On June 24 1914 King Peter, whose health had completely broken down, appointed him as prince regent, and he thus held the position of commander-in-chief when the World War broke out. He remained permanently at army headquarters, and shared with his soldiers all the privations of the retreat through Albania. On reaching the coast he fell ill and underwent a serious operation, but when already convalescent resolutely declined the proffered assistance of an Italian destroyer which had been sent to convey him across the Adriatic; he remained till all the refugees had been transported into safety, and eventually found his way on foot to Durazzo. After the exiled Serbian Government had established itself at Corfu, Prince Alexander and Mr. Pašić paid visits to Paris and London, where the Prince was received with warm ovations. On April 5 1916, in receiving an important deputation of British sympathizers (led by the Archbishop of Canterbury, the Lord Mayor, Lord Milner and Sir E. Carson), he publicly identified the dynasty with the cause of unity, expressing his conviction that in the final victory "our Yugo-Slav people, united in a single state, will also have their part." During the rest of the war he remained at Serbian headquarters, and shared his army's victorious advance in Oct. 1918. On Dec. 1 delegates of the Yugo-Slav National Council in Zagreb formally recognized him as regent in all the Yugo-Slav provinces of the former dual monarchy, and he assumed the title of "Prince-Regent of the Serbs, Croats and Slovenes." The attempt made upon his life on June 28 1921, after he had taken oath to the new Yugo-Slav constitution, was the outcome not of any personal unpopularity, but of the subversive aims of the Communists and other revolutionary groups, who hoped to create confusion in the new state, owing to the lack of a direct heir to the throne. On Aug. 16 1921 Prince Alexander succeeded his father as King of Yugoslavia.

ALEXANDER, BOYD (1873–1910), British soldier and explorer, was born at Cranbrook, Kent, Jan. 16 1873. He was educated at Radley, and afterwards entered the army, joining the Rifle Brigade in 1893. In 1897 he led a scientific expedition to the Cape Verde Is., and in 1898 went on his first African journey to the Zambezi and Kafuk rivers. He was appointed to the Gold Coast constabulary in 1900, and took part in the relief of Kumasi. In 1904 he led a scientific expedition to Fernando Po, where he ascended Mt. St. Isabel and discovered various new species of birds. The same year saw the commencement of his most important work—the Alexander-Gosling expedition across Africa from the Niger to the Nile, which occupied three years. During this period he surveyed the shores of Lake Chad and explored a considerable part of eastern Nigeria, returning to England by way of the rivers Ubangi, Shari and Nile. For his various discoveries he received gold medals from the Royal Geographical Societies of London and Antwerp, besides honours from other learned societies. He returned to Africa in 1908, and was killed by natives at Nyeri, in Wadai, April 2 1910. Alexander published *From the Niger to the Nile* (1907), besides many articles and papers in scientific and geographical periodicals.

See Herbert Alexander, *Boyd Alexander's Last Journey*, with a memoir (1912).

ALEXANDER, SIR GEORGE (1858–1918), English actor (*see* 1.564), died at Chorleywood, Herts., March 16 1918. He was knighted in 1911. Among his later productions at the St. James's theatre were R. S. Hichens's and J. B. Fagan's *Bella Donna;* Pinero's *The Big Drum* and Louis N. Parker's *The Aristocrat;* in this he made his last appearance together with the veteran actress Geneviève Ward.

ALEXANDER, JOHN WHITE (1856–1915), American painter (*see* 1.564), died in New York June 1 1915. He received a first-class medal from the Carnegie Institute, Pittsburgh, in 1911, and a medal of honour at the Panama-Pacific Exposition in 1915. He had been president of the National Academy of Design since 1909.

ALEXANDER, WILLIAM (1824–1911), Protestant Archbishop of Armagh and primate of All Ireland (*see* 1.565), who resigned his see Jan. 30 1911, and was created G.C.V.O., died at Torquay Sept. 12 1911.

ALEXEYEV, MIKAIL (1857–1918), Russian general, was born in 1857, and entered the army in 1876. He completed his studies at the General Staff College in 1890, and joined the Russian General Staff. In 1904 he became a general. He took part in the war with Turkey in 1877–8. During the Russo-Japanese War he was the director of the operations on the staff of the II. Army. After further staff service he became in 1912 commander of the XIII. Army Corps. At the outbreak of the World War he was nominated chief of the staff of the south-western front. The first operations were skilfully carried on by him, and the great Russian victory in Galicia in 1914 was his work. In March 1915 he was called to command the group of armies of the north-western front. A stupendous task awaited him here; eight armies were confided to him, but these masses were destitute of all means of combat. The events in Galicia in April 1915 had their repercussion further north, where the position became desperate, and the army seemed lost. But by the end of Aug. the armies

[illegible] saved, thanks to the energy and ability of [illegible]. In Aug. 1915 he was appointed chief of the [illegible] of the supreme command, and worked there with the Emperor, who had just assumed the supreme command. He served in this capacity during the successful campaign of 1916, until in Nov. a breakdown of health compelled him to give up his office. After the revolution of March 1917 he became commander-in-chief, but in May 1917 he was dismissed. Recalled by Kerensky in Sept. he remained at headquarters only 11 days in order to exercise a steadying influence during the conflict between Kornilov and Kerensky, and then left, being unable to work with men who he considered had brought misfortune and shame on his country. At the commencement of the Bolshevik régime he went to the south of Russia, where he soon became the leader of the "Volunteer Army," and took the field against the Bolsheviks. He died of heart disease Oct. [illegible] 1918.

ALGERIA (see 1.642).—The figures of the 1921 census showed a total pop. for Algeria of [illegible], of whom 752,043 were Europeans. Of these 556,572 were French, 134,746 Spaniards, concentrated specially in the department of Oran, and 36,661 Italians, in the region of Constantine.

The administration of the country was still in 1921 in the hands of a governor-general residing at Algiers, as supreme head of all the civil services, with the exception of the non-Mussulman services of justice, worship, public instruction, treasury and customs, which remained attached to the French ministerial departments. The governor-general has to assist him a general secretary and a Government council. Since 1900 Algeria has enjoyed a large measure of budgetary autonomy. The governor-general submits a special budget to the vote of Algerian representative assemblies, or the financial delegations which were created in 1898. The delegations are divided into three sections, one of which represents colonists, another non-colonising taxpayers, and the third native Mussulmans. The budget, when voted by the financial delegations, is submitted to the French Parliament. The estimates for 1922, comprising both ordinary and extraordinary revenue and expenditure, amounted to 595,000,000 francs.

The northern portion of the territory is administered under two systems, one civil and the other military. In the civil zone the administration is that in force in France. This zone is divided into three departments, Oran, Algiers, and Constantine, with prefects, general councils and sub-prefects as in France. Each department elects two deputies and one senator to the French Parliament, only French citizens having the right to vote. The military zone is divided into three administrative regions, under the control, subject to the governor-general, of generals of division. These regions are cut up again into sectors administered by officers of the Department for Native Affairs. In accordance with the composition of the population, three methods of local administration are employed. In the "full" communes there are municipal councils, elected by the townspeople; in the "mixed" communes public services are run by an administrator, assisted by a non-elected municipal council; the "native" communes are ruled by kaids with the assistance of native advisers, who are appointed by the governor-general.

The colonization of Algeria was rendered difficult by the presence of a native population which already had its own civilization, and was nomad and warlike in its instincts. A start was made in the region of the Tell, and then the mountains and high plateau-lands were taken in hand. There has been a spontaneous flow of Italian and Spanish immigration, and a system of land grants and other concessions have attracted large numbers of immigrants from the south of France who have settled down well in the country. Between 1904 and 1914, 206,000 hectares of land had been settled, of which 91,200 were free grants.

Agriculture has made great strides in spite of the difficulty of irrigation. By a judicious system of barrages and canals, the torrential rains have been harnessed up and spread over the land. Much has been done also to fight the locust, and to carry out a methodical policy of manuring. The results obtained have been brilliant. In the Tell wheat and wine are grown on a large scale, and indeed [illegible] wine. [illegible] which [illegible] fluctuates [illegible] 1918, 181 [illegible] million; [illegible] Olive plantations produce [illegible] Vegetables, fruit, medicinal plants and cork are the other chief agricultural products of the Tell. Cotton is grown in the Oran and in Algiers, and great efforts have been made to increase the output of tobacco, of which over 24,000 [illegible] were produced in [illegible]. On the tablelands the chief produce is alfa, which covers vast areas. It is exported in very large quantities to Great Britain, where it is used in the manufacture of good quality paper. The alfa exports in 1919 were 811,997 quintals; in 1918, [illegible] quintals, and in 1920, [illegible] quintals, of the value of 22½ million francs. Sheep form the chief stock of the country. Forests cover well over two million hectares, the Woods and Forests service alone having that area under its control. Cork trees cover over 400,000 hectares.

Mines.—The country is rich in minerals, which, however, have not been thoroughly exploited. The chief mineral resource is iron, the exports of which in 1920 amounted to 1,114,438 tons, valued at 32,879,000 francs. There are large phosphate deposits in the Constantine province, which exported 334,704 tons in 1920 to a value of 18½ million francs. There are also copper, zinc, lead, and antimony mines. Coal deposits were discovered during the war, and the work of British and American prospectors in the Oran indicates the possibility of existence of oil fields of some size. In 1900, Algeria possessed only 1,771 m. of railway; that figure had by 1921 been brought to [illegible], and many new lines were being considered. The three chief ports handled the following traffic in 1920: Algiers, 6,264,735 tons; Oran, 2,975,762 tons; Bona, 1,106,362 tons. A great deal of work has been done in improving the road system of the country, and motor-ways have been built from Tuggurt to Timbuktu. An aerial postal service has also been organized.

Commerce.—The general trade in 1920 amounted to 4,342,000,000 francs, and special trade, that is to say, trade arising exclusively from the requirements and produce of the colony, amounted to 3,977,000,000 francs, of which 2,535,000,000 were imports, and 1,442,000,000 exports. Of this trade, France took respectively 1,991,862 francs, and 1,096,472 francs. These figures show a very large increase, the general trade in 1918 amounting only to 1,529,000,000 francs, and in 1919 to 2,287,900,000 francs. In 1913, the last normal year before the war, the figure was 1,292,000,000, of which 729,000,000 were imports, and 563,000,000 were exports. In judging of these figures, the drop in the value of money has to be borne in mind.

Native rights.—The valuable help given by the native population of Algiers to France during the World War led, as it did in other parts of the French colonial empire, to a wider recognition of the political rights of the native. A law was passed, Feb. 4 1919, conferring French citizenship on any native of Algeria who had either served in the French army or navy, was a land-owner, farmer, or licensed trader, knew how to read and write French, or was the possessor of a French decoration. Native Mussulmans who did not receive French citizenship, are represented in all the deliberative assemblies by elected members who sit with the same rights as those enjoyed by the French members of such assemblies. With some exceptions they are admitted to public service on the same footing as French citizens. In the beginning of 1919 the special Arab taxes, which were supported by the native population alone, were done away with, and their place was taken by income and property taxes. It was proposed to form an Algerian consulting committee in Paris, in which natives would sit. (M. R.*)

ALLBUTT, SIR THOMAS CLIFFORD (1836–), English physician, was born at Dewsbury, Yorks., July 20 1836. He was educated at St. Peter's, York, and Caius College, Cambridge, where he took a first class in the natural science tripos in 1860. He studied medicine at St. George's Hospital and afterwards in Paris, subsequently practising in London and Leeds. He carried out many researches on the pathology of the nervous system, and made important studies of tetanus and hydrophobia. He also devoted much time to the study of ophthalmoscopy, and was the inventor of the short clinical thermometer. He was consulting physician to many institutions, and from 1889 to 1892 was a commissioner in lunacy. In 1892 he became Regius professor of physic at Cambridge, and in 1907 was created K.C.B. Sir Clifford Allbutt was a member of many Government committees, including the Home Office inquiry into trade diseases, and during the World War he was an hon. colonel in the R.A.M.C.

His published works include *The Ophthalmoscope in Medicine* (1871); *On Scrofula* (1885); *Diseases of the Heart* (Lane lectures, 1896); *Historical Relations of Medicine and Surgery* (1905); *Greek Medicine in Rome* (Fitzpatrick lectures, 1909-10); *Diseases of the Arteries and Angina Pectoris* (1915) and *Science in the School*

(1957). He also edited [illegible] 1899, 1903).

ALLEN, SIR JAMES [illegible] New Zealand statesman, was born in South A[illegible] Feb. [illegible] and went to New Zealand about 1858. He was educated at Clifton College and St. John's College, Cambridge, where he held a natural science exhibition. At Cambridge he played in the University Rugby football fifteen and took his M.A. degree; and he afterwards studied at the Royal School of Mines and won the Bessemer and de la Beche medals. In 1887 he made a remarkable entry into politics by winning the Dunedin East seat from Sir Robert Stout, then Premier and Liberal leader, by 29 votes. Losing this seat at the general election of 1890, he represented Bruce from 1892 till his resignation in 1920. He has always taken a special interest in educational, military and imperial questions; was a member of the Otago University council and served a term as chancellor, and from 1908–12 was a member of the New Zealand University senate. He was for many years an enthusiastic volunteer, and was promoted lieutenant-colonel in 1909.

During the 21 years of Mr. Allen's service in opposition he showed himself a keen critic of the Liberal administration, especially on financial matters. On defence questions he always spoke with authority and without party bias. The movement for compulsory military training, which came to a head in 1909, had his hearty support, and it is certain that the extension of the Territorial age-limit from the 22nd to the 25th year, which Lord Kitchener recommended, could not have been carried by the Ward government in 1910 without the help that Mr. Allen gave to it. When the Reform party came into power in 1912 Mr. Allen became Mr. Massey's right-hand man. He held the three onerous portfolios of Defence, Finance, and Education in the first Massey administration (1912–15). His prudence and caution inspired confidence in his budgets, and both in military and in naval defence he gave the country a strong lead. His proposal in 1913 to organize an Expeditionary Force of 8,000 men for oversea service was severely criticized, but its value was duly appreciated in the following year. Regarding naval defence he insisted strongly on the inadequacy of a mere cash payment to the Admiralty to discharge the obligations of a self-respecting state, and with Mr. Massey he laid, in the Naval Defence Act, 1913, the foundations of a policy of self-reliance, with the proviso that the Dominion's naval forces should automatically pass into the control of the Admiralty in time of war.

As a member of the National Government which was formed as a result of the Massey-Ward war coalition Sir James Allen retained the portfolio of Defence, and he held it throughout the life of that Government (1915–9) and until his retirement from the succeeding Massey government in March 1920. It is impossible to exaggerate the value of his services in that capacity. He faced all the problems of organizing a young and untried democracy for the World War, first under a voluntary and then under a compulsory system, with a resolution that never faltered, and he saw it through. During the first year or two of the war the Defence Minister was probably the most unpopular man in the Dominion, but there was afterwards a strong reaction in his favour, and towards its close the sterling value of his services was universally recognized. There was certainly no other man to whom the Dominion was more deeply indebted for the excellence of its war record.

During the long absences of Mr. Massey and Sir Joseph Ward on the business of the Imperial War Cabinet in 1916, 1917 and 1918 and of the Peace Conference in 1919 Sir James Allen had the responsibilities of Acting-Prime Minister as well as those of Defence. He retired from politics in 1920 in order to succeed Sir Thomas Mackenzie as the Dominion's High Commissioner in London on July 31. Few statesmen who have so persistently violated the politician's rule of putting all the best goods in the front window have been privileged to retain the confidence of a democracy so long and to render it such admirable service. He was made a K.C.B. in 1917. He married Mary Hill Richards of Somerset, England, in 1877 and has two sons and three [illegible]

[illegible]

Allenby, was born April 23, 1861, and joined the Inniskilling Dragoons in 1882. His first few years [illegible] in South Africa, where he [illegible] expedition of 1884–5 and in [illegible] After returning to England with his regiment he passed through the Staff College and in 1896 he married Adelaide Mabel Chapman. He went out to South Africa again as a squadron leader in 1899 and took part in the important cavalry operations by which Kimberley was relieved, in the battle of Paardeberg, and in Lord Roberts's advance to Pretoria and into the eastern Transvaal. During the later phases of the South African War he made a great name for himself as a column commander, and he was for his services promoted brevet lieutenant-colonel and colonel and given the C.B. He then commanded the 5th Lancers from 1902–5, and for the next four years he was at the head of a cavalry brigade, being promoted major-general in 1909. He became inspector of cavalry in 1910 and, as holding that position, went out to France with the Expeditionary Force in 1914 in charge of the cavalry division.

The work of his mounted troops during the retreat from Mons, the subsequent advance to the Aisne, and the first battle of Ypres won great praise, and on a second cavalry division being formed Allenby was appointed commander of the newly constituted Cavalry Corps. He was about the same time given the K.C.B. In June 1915 he was transferred from this to the command of the 5th Army Corps; but he held that position for only a short time as, in the following Oct. on Gen. Monro's proceeding to the Near East, he succeeded that general as chief of the 3rd Army, which he led for nearly two years. His army was not called upon to undertake operations on any large scale during 1916, but it shared to some extent in the later stages of the battle of the Somme. In 1917, on the other hand, it was very heavily engaged in the Arras region during the spring months and won much valuable ground. Allenby had been promoted lieutenant-general in 1916, and in June 1917 he was selected for the command of the troops in Egypt and Palestine, where elaborate preparations had been made for an offensive campaign; he was at the same time promoted general.

The season was unsuitable for active operations on the borders of the Holy Land for the first three months after his arrival in Egypt, but these were spent in perfecting preparations for an advance, which began at the end of Oct. with the capture of Beersheba and the taking of Gaza a few days after. These successes were followed up relentlessly. Jaffa fell Nov. 17, the Turks were driven with loss out of every position that they tried to take up, and, after vain efforts on their part to bar the way to Jerusalem, that city was surrendered Dec. 9. Allenby, who had been given the G.C.M.G. for these achievements, materially improved his position during the next four months, but he was then obliged by events in France to despatch some of his troops to the western theatre of war.

During the summer of 1918 fresh forces from India and Mesopotamia took the place of the troops sent away, and in Sept. the British commander struck with crushing effect. By a sudden advance in great force the Turkish front was broken, the plain of Esdraelon was flooded with mounted men, the infantry moved irresistibly forward and, as the result of a masterly combination of war, the enemy suffered an overwhelming defeat. All arrangements had been made in advance for instantly following up the anticipated victory; within a very few weeks Damascus and Beirut had been occupied, troops had been thrust right up to Aleppo, and not only Palestine but also all Syria were in the hands of the Allies. Allenby's brilliant services were recognized by his being given the G.C.B., and, on the general distribution of honours for the war in 1919, he was promoted field marshal and was raised to the peerage as Viscount Allenby of Megiddo and Felixstowe; he was at the same time awarded a grant of £50,000.

While engaged in his campaigns of conquest beyond the Egyptian borders Allenby had also been responsible for maintaining order in the Nile delta and for its protection against attack from without, matters that had at times given grounds for anxiety as there was much unrest due to the abnormal situation that existed. In 1919 he was definitely appointed British High Commissioner in Egypt.

ALLENSTEIN-MARIENWERDER, a region composed of districts of the former Prussian provinces of East and West Prussia, in which a plebiscite was taken, under the Treaty of Versailles, on June 11 1920.

Art. 94-98 of the Treaty of Versailles provided that the East Prussian Circles (Kreise) of Allenstein, Osterode, Ortelsburg, Sensburg, Johannisburg, Lötzen, Lyck and Neidenburg, in so far as they had not already been ceded to Poland, and further the West Prussian Circles of Marienwerder (east of the Vistula), Stuhm, Rosenberg and the section of the Circle Marienburg situated east of the Nogat, should declare by a plebiscite whether they desired to belong to Germany or Poland. Until the plebiscite should take place the administration of these Circles was taken over by interallied commissions for East and West Prussia respectively. The commissions were composed of representatives of England, France, Italy and Japan. Troops for occupying the districts were provided by France, England and Italy. Two German commissions conducted the negotiations with the interallied commissions.

The whole territory has an extent of about 15,000 sq. km., and a pop. of about 855,000, of which 695,000 belong to the East Prussian plebiscitary area and 160,000 to the West Prussian. Racially the population in the East Prussian region numbers 428,000 Germans, 95,000 Poles and 172,000 Masurians, who are Slavs but of the Protestant faith. In the West Prussian region the Circle Stuhm has 21,000 inhabitants who speak German and 15,000 who speak Polish; the Circle Marienburg has 26,500 German-speaking and 1,500 Polish-speaking; Rosenberg 47,000 German-speaking and 3,500 Polish-speaking; Marienwerder 17,500 German-speaking and 25,000 Polish-speaking inhabitants.

The date of the plebiscite was fixed originally for June 11 1920. Long before that date a vigorous agitation was opened by both sides. There were repeated actual encounters in different places, mostly excited by Polish bands, the so-called *Bajowkas*, recruited from Congress Poland, and the territory of Posnania which has been ceded under the Treaty. The Polish agitation, however, did not produce any marked results either in West Prussia or in East. In both regions leagues which agitated for Poland were from the native Polish and Masurian elements of the population, but in the course of the plebiscitary campaign they went over to the Germans. The plebiscite, ultimately held on July 11, resulted in an astonishing German victory.

In the East Prussian region 98% of the population voted for Germany, in the West Prussian 92%. The result was celebrated by joyous festivities in all the East and West Prussian polling centres. Both the districts were assigned to Germany on the basis of the vote; but, in accordance with the terms of the Treaty of Versailles, a zone 50 m. broad and some 30 m. long on the east bank of the Vistula near Marienwerder and four villages with the harbour of Kurzebrack on the same river were assigned to Poland in order to secure for the Polish State, at this point, the sovereignty over the course of the Vistula accorded to it by the Treaty. The inhabitants of the adjacent East Prussian territory are at all times to have access for themselves and their boats to the Vistula. Three frontier communes in the south-west of East Prussia were also assigned to Poland. On Aug. 16 both the interallied commissions left the plebiscitary areas, which were thus once more subjected to German administration. The agitation in favour of Germany had been to a considerable extent conducted by the so-called *Heimatsdienst*, a patriotic German society which had spread its organization over the whole of the plebiscitary areas. (C. K.*)

ALMA-TADEMA, SIR LAURENCE (Laurens) (1836–1912), British painter (*see* 1.712), died at Wiesbaden June 25 1912. The most important of his later works was "Caracalla and Geta" (1907). An exhibition of his works was held in London 1913.

ALPHONSO XIII. (1886-), King of Spain (*see* 1.736). On returning from a military review April 13 1913, an attempt against the King's life was made by an anarchist, who shot at him but only succeeded in wounding the horse. The children born to the King are: Alphonso, Prince of the Asturias, May 10 1907; Jaime, June 23 1908; Beatriz, June 22 1909; Maria Cristina, Dec. 12 1911; Juan, June 20 1913; Gonzalo, Oct. 24 1914. During the World War the King, as ruler of a neutral country, though scrupulously preserving a neutral attitude, rendered great services to the Allies by his intervention on behalf of prisoners of war and his efforts to ascertain the fate of men reported "missing." (*See further* SPAIN.)

ALSACE-LORRAINE (*see* 1.756).—As the result of the World War there is no longer any "Alsace-Lorraine." The erstwhile *Reichsland*, conceived by Bismarck in 1871, ceased to exist in Nov. 1918. As before 1870, there are now again the French departments of the Bas-Rhin (Strasbourg), the Haut-Rhin (Colmar) and the Moselle (Metz). The return of the former Alsace-Lorraine to the French mother-country took place amidst the indescribable pleasure of the restored populations.

In 1921 the three departments were passing through a transition period. The Germans did not occupy the country for nearly half a century without trying to leave their mark on it, without introducing their administrative methods and laws, which sometimes differ completely from those of French administration and legislation. The Government in Paris came to the conclusion that to transplant the reconquered provinces in a day from German to French ways would be to risk confusions and upsets which it would be preferable to avoid; it was thought that there was a considerable work in legislative assimilation, adaptation and adjustment, to accomplish. It was for this reason that after the Armistice a High Commission of the Republic was established at Strasbourg, comprising many departments and many different services. The General Commission of the Republic is directly attached to the prime minister's office, the affairs of the three departments being centralized in the hands of the under-secretary of the presidency.

The first High Commissioner, M. Georges Maringer, was replaced in April 1919 by M. Alexandre Millerand, who went to Strasbourg with extended powers, and the title of General Commissioner. Called in Jan. 1920 to the premiership of France, M. Millerand had as successor M. Gabriel Alapetite, former resident-general for France at Tunis, and ambassador at Madrid.

Administration.—The general lines upon which French legislation was to be introduced were fixed by the law of Oct. 17 1919, concerning the transitional administration of the recovered provinces. This law settles the transitional methods to be applied to administrative, electoral and financial organization. On the other hand, constitutional laws are not dealt with, because they are *ipso facto* applicable by the reintegration of Alsace and Lorraine with France.

The law of Oct. 17 1919 maintains in force the legislative arrangements and local regulations (German law or special Alsace-Lorraine law) until the introduction of French laws shall have been effected. The authority of the military governors of Strasbourg and Metz is subordinated to the civil power. Article 4 of this law lays down in principle that it is for Parliament to decide what temporary measures shall be introduced pending the definitive introduction of French legislation. The same law establishes that the French fiscal system shall gradually be substituted for that of Germany. The electoral system is that of France. The former Alsace-Lorraine has kept certain laws passed during German rule; for instance, the laws affecting social insurance. In religious matters, the Republican Government has respected the *status quo*—that is to say, the Concordat is maintained, also the denominational schools.

It is abundantly apparent that the Government is keeping the solemn promise made during the war by French statesmen and generals to the effect that the customs and beliefs of the people would be respected. The mission of the Commissioner-General is extremely delicate. He has departmental responsibility in these three departments unknown in others. He has to determine how, in what length of time, and with what precautions French laws can be successively applied there. In submitting legislation, he has to inform Parliament as to the gravity of the disturbance which changes must make in settled habits and customs, and as to the difficulties accompanying the return to French rule.

A consultative council has been provisionally instituted in connexion with the High Commission of the Republic. It comprises 35 members, of whom 3 are senators, 6 deputies, 21 local councillors, and 5 named by the decision of the prime minister. This body deliberates and pronounces upon all questions which fall outside the limits of any one public department, and are submitted to it by the Commissioner-General. It is *compulsorily* consulted on the budget of revenue and expenditure in Alsace-Lorraine and on all proposed modifications of the fiscal system in force; as also on all administrative or economic bills and regulations affecting the combined populations of the three departments. The consultative council is convoked by the Commissioner-General at least four times a year. Thus the Commissioner-General has at hand a body in which the representatives of the different populations can show forth the interests of these latter and, by expert advice, can facilitate the study and solution of questions common to the Haut-Rhin, the Bas-Rhin, and the Moselle. But this body is purely consultative. The Government of the Republic keeps its power of initiative and its responsibilities; Parliament remains the sovereign power.

Population.—The recovered departments are administered like the other French departments. The department of the Bas-Rhin (*préfecture* Strasbourg) includes 8 *arrondissements:* Strasbourg-Ville; Strasbourg-Campagne; Erstein; Haguenau; Molsheim; Sélestat; Wissembourg; Saverne. Its superficial area is 4786·37 square kilometres. There are 561 *communes.* The pop. numbers 608,116. The department of the Haut-Rhin (*préfecture* Colmar) includes 6 *arrondissements:* Altkirch; Colmar; Guebwiller; Mulhouse; Ribeauvillé; Thann. Area 3,507·7 sq. km.; 386 *communes;* pop. 430,988. The department of the Moselle (*préfecture* Metz) includes 9 *arrondissements:* Moselle-Ville; Moselle-Campagne; Boulay; Château-Salins; Forbach; Sarrebourg; Sarreguemines; Thionville-Ouest; Thionville-Est. Area 6,227·8 sq. km.; 758 *communes;* pop. 554,445. The combined population according to the census of March 6 1921 is, therefore, 1,593,549, as against 1,874,014 at the time of the last German census in 1910.

The falling-off in the number of the population can be attributed in the first place to the war. Alsace and Lorraine had lost in dead and missing about 45,000 men. Moreover, militarist Germany kept in the three departments no less than 82,276 soldiers. The German and Austro-Hungarian subjects domiciled in Alsace and in Lorraine before the war numbered 301,764. The number of German civilians who had left Alsace and Lorraine after the Armistice up to April 1 1921 was 76,467. These departures were partly balanced by the fact that many French subjects from the home country settled in the recovered provinces.

Before the war there were in the imperial territory 1,428,343 Catholics, 408,274 Protestants, 30,483 Jews. The percentage of illegitimate births was 7·52. In 1921 in Strasbourg there were 165,-835 inhabitants; in Mulhouse 98,393; Sarreguemines 14,318; in Thionville 13,410; in Guebwiller 11,520; in Forbach 10,475; in Sélestat 9,846; in Ste. Marie-aux-Mines 9,395; and in Sarrebourg 8,290.

Agriculture.—Agricultural production in 1920 amounted to 160,755 tons of wheat, 57,351 tons of rye, 71,829 tons of barley, 126,487 tons of oats, 1,025,424 tons of potatoes, 44,174 tons of sugar-beet. Alsace provided one-eighth of the whole world production of hops: the crop of 1920 amounted to 3,355 tons. The wines of Alsace are nearly all white wines, of an exquisite flavour and bouquet, yielding nothing to the German wines of the Moselle and the Rhine. Rich in alcohol, they are very suitable for export. The Moselle produces in particular *vins gris* and red wine. The vintage of 1920 reached 725,000 hectolitres as against 734,000 in 1919. The value of the 1920 vintage was 124,000,000 frs. The average tobacco crop is 4,000,000 kilograms.

Mineral Wealth.—While petroleum and potash are found in Alsace the Moselle is rich in iron ore and coal. The oil lands stretch out to the E. of Woerth (Wörth) in the Bas-Rhin, where the Pechelbronn field is situated. Between 1913 and 1921 about 3,000 borings were made and over 500 pumps were installed in this field. The average output during 1918–9 was 49,225 tons. The total yield up to 1921 had been about 900,000 tons, and the available supplies were estimated at 5½ million tons. Oil refineries with a treatment capacity of 73,000 tons a year have been built at Pechelbronn. The State acquired these deposits in 1921, and handed over their exploitation to a private company, mainly formed by local interests.

The return of the department of the Upper Rhine to France deprives German industry of the monopoly of potash. Potash was discovered in large quantities in 1904 in Alsace by the Alsatian Vogt. The area concerned covers about 200 sq. km. of country and is to the N. of Mulhouse. The output for 1919 was 512,000 tons and for 1920 1,222,609 tons. This represents an increase of 249 % over the last pre-war figures. An annual yield of between five and six million tons was expected before long.

By the liberation of Alsace-Lorraine France became the largest European producer of iron ore, with an annual yield of 42 million tons. There are 50 mines in Lorraine. Output reached its height in 1913 with 21,133,676 tons, a downward curve being shown by later figures, which are as follows:—

Year	Tons
1914	14,014,137
1915	10,754,551
1916	13,286,302
1917	13,614,139
1918	10,477,673
1919	7,137,206

After the Armistice there was a steady drop in output, due to post-war difficulties of all kinds: the year 1919 was for the whole field a period of reconstruction. Output between Jan. and Sept. 1920 amounted to six million tons. The mines employed 17,237 men in 1913 as compared with 9,523 in 1919. In 1913 German labour was 60 % of the total. In 1920 it was 32·2 %.

The output of coal also reached its maximum in 1913, the figures being:—

Year	Tons
1913	3,795,262
1914	2,856,752
1915	1,960,963
1916	2,027,684
1917	2,636,802
1918	2,662,046
1919	2,310,589

The fresh fall in 1919 was due to strikes and the reduction in working hours. Seven-tenths of the coal is consumed by local industry. The Lorraine salt mines produced 28,822 tons in 1919 as compared with 59,091 tons in 1913.

Public Instruction.—Strasbourg University was opened by President Poincaré on Nov. 22 1919. By the end of 1920 the six faculties and the Pharmaceutical School had 1,889 students. The lectures are given in French.

Secondary education is provided by the many *lycées* created throughout the country. French naturally is the chief language, but German has been allowed to have the place which is its due in view of the special situation of the provinces.

The language question has been more difficult to solve in primary schools. Before 1870 France had neglected the importance of teaching French in the primary schools of Alsace. Since 1920 the teaching has been in French throughout the country. An exception is however made for religious teaching (4 hours a week) which is given in German in those districts where the Alsatian dialect is the mother-tongue of the inhabitants. The religious character of schools has been respected. In view of the bilingual character of the country a large amount of time is given to the study of German in schools. The population is very well educated. Before the war there were only eight illiterates among the contingent of army recruits (97,694).

Industry.—After 1880 Alsace-Lorraine had been turned industrially towards Germany. In 1914 Alsace-Lorraine exported 1,576,-000 tons of goods, 908,000 tons of which went to Germany. In 1909 eight out of ten and a half million tons of exports went to Germany, while nearly five-sixths of Alsace-Lorraine imports came from Germany. The preponderant part of Germany is naturally explained by the fact that while trade was free with Germany it was impeded with France by the customs wall. It is not possible by a stroke of the pen to change the commercial orientation of a country nor to find at once new markets for its products. Therefore the Treaty of Versailles laid down that for a period of five years nothing should be changed from the customs point of view in the relations between the recovered provinces and Germany.

In Alsace the textile industry is by far the most important, especially in spinning, weaving and printing. France, thanks to the restoration of the province, finds her productive power increased by 26 % in spinning and by 30 % in weaving. Large quantities of sewing and embroidery thread are also produced.

In Lorraine iron and steel industries are at the head. There are 68 furnaces with an annual capacity of 3,800,000 tons of pig-iron. The production fell from 3,460,000 tons in 1913 to 1,129,000 tons in 1919. The steel output in 1913 was 22,260,000 tons and in 1919 it had fallen to 871,000 tons. This drop is to be attributed entirely to coal and coke shortage. There were 22,000 workmen employed by the industry.

Communications.—The railway system is excellent and had been developed greatly by the Germans, mainly from a strategic point of view. The railways have preserved their autonomy and constitute a special system attached to the Ministry of Public Works. In 1920 the traffic amounted to 2,253,000,000 tons of goods.

The canal system is good, but the great waterway is naturally the Rhine. The port of Strasbourg with its modern equipment is the

While engaged in his campaigns of conquest beyond the Egyptian borders Allenby had also been responsible for maintaining order in the Nile delta and for its protection against attack from without, matters that had at times given grounds for anxiety as there was much unrest due to the abnormal situation that existed. In 1919 he was definitely appointed British High Commissioner in Egypt.

ALLENSTEIN-MARIENWERDER, a region composed of districts of the former Prussian provinces of East and West Prussia, in which a plebiscite was taken, under the Treaty of Versailles, on June 11 1920.

Art. 94-98 of the Treaty of Versailles provided that the East Prussian Circles (Kreise) of Allenstein, Osterode, Ortelsburg, Sensburg, Johannisburg, Lötzen, Lyck and Neidenburg, in so far as they had not already been ceded to Poland, and further the West Prussian Circles of Marienwerder (east of the Vistula), Stuhm, Rosenberg and the section of the Circle Marienburg situated east of the Nogat, should declare by a plebiscite whether they desired to belong to Germany or Poland. Until the plebiscite should take place the administration of these Circles was taken over by interallied commissions for East and West Prussia respectively. The commissions were composed of representatives of England, France, Italy and Japan. Troops for occupying the districts were provided by France, England and Italy. Two German commissions conducted the negotiations with the interallied commissions.

The whole territory has an extent of about 15,000 sq. km., and a pop. of about 855,000, of which 695,000 belong to the East Prussian plebiscitary area and 160,000 to the West Prussian. Racially the population in the East Prussian region numbers 428,000 Germans, 95,000 Poles and 172,000 Masurians, who are Slavs but of the Protestant faith. In the West Prussian region the Circle Stuhm has 21,000 inhabitants who speak German and 15,000 who speak Polish; the Circle Marienburg has 26,500 German-speaking and 1,500 Polish-speaking; Rosenberg 47,000 German-speaking and 3,500 Polish-speaking; Marienwerder 17,500 German-speaking and 25,000 Polish-speaking inhabitants.

The date of the plebiscite was fixed originally for June 11 1920. Long before that date a vigorous agitation was opened by both sides. There were repeated actual encounters in different places, mostly excited by Polish bands, the so-called *Bajowkas*, recruited from Congress Poland, and the territory of Posnania which has been ceded under the Treaty. The Polish agitation, however, did not produce any marked results either in West Prussia or in East. In both regions leagues which agitated for Poland were from the native Polish and Masurian elements of the population, but in the course of the plebiscitary campaign they went over to the Germans. The plebiscite, ultimately held on July 11, resulted in an astonishing German victory.

In the East Prussian region 98% of the population voted for Germany, in the West Prussian 92%. The result was celebrated by joyous festivities in all the East and West Prussian polling centres. Both the districts were assigned to Germany on the basis of the vote; but, in accordance with the terms of the Treaty of Versailles, a zone 50 m. broad and some 30 m. long on the east bank of the Vistula near Marienwerder and four villages with the harbour of Kurzebrack on the same river were assigned to Poland in order to secure for the Polish State, at this point, the sovereignty over the course of the Vistula accorded to it by the Treaty. The inhabitants of the adjacent East Prussian territory are at all times to have access for themselves and their boats to the Vistula. Three frontier communes in the south-west of East Prussia were also assigned to Poland. On Aug. 16 both the interallied commissions left the plebiscitary areas, which were thus once more subjected to German administration. The agitation in favour of Germany had been to a considerable extent conducted by the so-called *Heimatsdienst*, a patriotic German society which had spread its organization over the whole of the plebiscitary areas. (C. K.*)

ALMA-TADEMA, SIR LAURENCE (Laurens) (1836–1912), British painter (*see* 1.712), died at Wiesbaden June 25 1912. The most important of his later works was "Caracalla and Geta" (1907). An exhibition of his works was held in London 1913.

ALPHONSO XIII. (1886–), King of Spain (*see* 1.736). On returning from a military review April 13 1913, an attempt against the King's life was made by an anarchist, who shot at him but only succeeded in wounding the horse. The children born to the King are: Alphonso, Prince of the Asturias, May 10 1907; Jaime, June 23 1908; Beatriz, June 22 1909; Maria Cristina, Dec. 12 1911; Juan, June 20 1913; Gonzalo, Oct. 24 1914. During the World War the King, as ruler of a neutral country, though scrupulously preserving a neutral attitude, rendered great services to the Allies by his intervention on behalf of prisoners of war and his efforts to ascertain the fate of men reported "missing." (*See further* SPAIN.)

ALSACE-LORRAINE (*see* 1.756).—As the result of the World War there is no longer any "Alsace-Lorraine." The erstwhile *Reichsland*, conceived by Bismarck in 1871, ceased to exist in Nov. 1918. As before 1870, there are now again the French departments of the Bas-Rhin (Strasbourg), the Haut-Rhin (Colmar) and the Moselle (Metz). The return of the former Alsace-Lorraine to the French mother-country took place amidst the indescribable pleasure of the restored populations.

In 1921 the three departments were passing through a transition period. The Germans did not occupy the country for nearly half a century without trying to leave their mark on it, without introducing their administrative methods and laws, which sometimes differ completely from those of French administration and legislation. The Government in Paris came to the conclusion that to transplant the reconquered provinces in a day from German to French ways would be to risk confusions and upsets which it would be preferable to avoid; it was thought that there was a considerable work in legislative assimilation, adaptation and adjustment, to accomplish. It was for this reason that after the Armistice a High Commission of the Republic was established at Strasbourg, comprising many departments and many different services. The General Commission of the Republic is directly attached to the prime minister's office, the affairs of the three departments being centralized in the hands of the under-secretary of the presidency.

The first High Commissioner, M. Georges Maringer, was replaced in April 1919 by M. Alexandre Millerand, who went to Strasbourg with extended powers, and the title of General Commissioner. Called in Jan. 1920 to the premiership of France, M. Millerand had as successor M. Gabriel Alapetite, former resident-general for France at Tunis, and ambassador at Madrid.

Administration.—The general lines upon which French legislation was to be introduced were fixed by the law of Oct. 17 1919, concerning the transitional administration of the recovered provinces. This law settles the transitional methods to be applied to administrative, electoral and financial organization. On the other hand, constitutional laws are not dealt with, because they are *ipso facto* applicable by the reintegration of Alsace and Lorraine with France.

The law of Oct. 17 1919 maintains in force the legislative arrangements and local regulations (German law or special Alsace-Lorraine law) until the introduction of French laws shall have been effected. The authority of the military governors of Strasbourg and Metz is subordinated to the civil power. Article 4 of this law lays down in principle that it is for Parliament to decide what temporary measures shall be introduced pending the definitive introduction of French legislation. The same law establishes that the French fiscal system shall gradually be substituted for that of Germany. The electoral system is that of France. The former Alsace-Lorraine has kept certain laws passed during German rule; for instance, the laws affecting social insurance. In religious matters, the Republican Government has respected the *status quo*—that is to say, the Concordat is maintained, also the denominational schools.

It is abundantly apparent that the Government is keeping the solemn promise made during the war by French statesmen and generals to the effect that the customs and beliefs of the people would be respected. The mission of the Commissioner-General is extremely delicate. He has departmental responsibility in these three departments unknown in others. He has to determine how, in what length of time, and with what precautions French laws can be successively applied there. In submitting legislation, he has to inform Parliament as to the gravity of the disturbance which changes must make in settled habits and customs, and as to the difficulties accompanying the return to French rule.

whom he admired above all other artists, he possessed probably the largest private collection ever assembled. Velazquez was well represented, as were Van Dyck, Cuyp, Ruysdael, Vermeer, and many others. These collections he bequeathed to the Metropolitan Museum of Art, New York City. Shortly before his death he secured the incorporation of the Altman Foundation, established for the welfare of the employees of the department store of B. Altman & Co., of which he was the head, thus crowning a career long devoted to unobtrusive philanthropy.

ALVERSTONE, RICHARD EVERARD WEBSTER, 1st Baron (1842–1915), Lord Chief Justice of England (*see* 1.775), died at Cranleigh, Surrey, Dec. 15 1915.

AMADE, ALBERT GÉRARD LÉO D' (1856–), French general, was born at Toulouse Dec. 27 1856. He was the son of an officer and was educated at La Flèche prior to entering the army in 1876. From 1887, when he became French military attaché at Peking, his military experience was peculiarly varied, and included, besides his four years in China, service as military attaché with the British forces during the S. African War, three years as French military attaché in London, and finally, as a general officer, the command of the expeditionary force in the Moroccan campaign of 1907. On the outbreak of the World War, he was, in accordance with the prepared scheme of operations which assumed Italy as an opponent, placed in charge of the "Army of the Alps." This group, however, had only a momentary existence. It became clear that Italy would remain neutral. D'Amade's troops were taken to reinforce other fronts and he himself was placed in charge of a group of forces formed in the region of Lille and Douai to resist as best it might the unexpectedly wide sweep of the German invasion. Weak numerically, composed wholly of territorial units of the oldest classes, improvised in point of organization and ill equipped, D'Amade's "army" was in no condition to attempt a vigorous counter-offensive or even a fixed defensive, and after a certain amount of fighting in the Cambrai region it was withdrawn to the extreme left, between Amiens and Abbeville, Gen. Maunoury's VI. Army taking its place. In the spring of 1915, when a French contingent was formed for service in the Levant, D'Amade was appointed to command it, and in this capacity led the French forces in the Dardanelles landing of April, and the trench warfare that followed. A gallant and knightly soldier, already experienced in the ways of his Allies, he was exceptionally well fitted to hold a command which, half subordinate, half independent, presented all possible opportunities of friction, and in fact few if any inter-Allied operations of the World War were conducted with so little friction as this. In May, however, he was recalled to France.

AMERICAN LITERATURE (*see* 1.831).—After the year 1910 the American novel developed mainly in the realistic manner, and in a rather remarkable way, the year 1920 being especially notable for the appearance of novels of distinction. The romantic revival in English and American fiction, which began in the last decade of the 19th century, had exhausted itself before 1910. It was succeeded by what might be called the "life" novel, where the entire history of the hero or heroine is given; even where this rather loose biographical method is not attempted, the realistic novels from 1910 to 1921 were marked by a fidelity to fact and a sincerity of composition which indicated promise for the future development of the art. Mark Twain and O. Henry died in 1910; Henry James in 1916; W. D. Howells in 1920. During recent years no one, either in the novel or in the short story, eclipsed the work of these men. But some important new writers appeared and two veterans showed increasing power. Booth Tarkington, born at Indianapolis in 1869, who had a wide reputation after 1899, began in 1914 a series of novels superior to anything in the preceding 15 years of his career. These later novels may be divided into two classes—those dealing with towns and those dealing with youth. In *The Turmoil* (1915) and in *The Magnificent Ambersons* (1918) he analyzed and described life in American cities; in *Penrod* (1914) and in *Seventeen* (1916) he gave a faithful analysis of the character of the American boy and of the American youth; while in *Alice Adams* (1921) he portrays with subtlety a young girl. It should also be mentioned that his sympathetic portraits of negroes were among the best ever produced. Edith Wharton's *Age of Innocence* (1920) is her masterpiece; it is a novel dealing with New York society in 1872, valuable for its consummate art and for the accuracy of its historical pictures. The new novelists, unknown before 1910, deal—with the single exception of Anne Douglas Sedgwick, who lived in England—wholly with American life and character. Dorothy Canfield, born at Lawrence, Kan., in 1879, produced two novels, *The Squirrel Cage* (1912) and *The Bent Twig* (1915), the latter describing life in a university in the middle-west, as well as *The Brimming Cup* in 1921, a remarkable study of a woman's nature and the grounds of her marital happiness. Zona Gale, born at Portage, Wis., in 1874, took in *Miss Lulu Bett* (1920) a familiar subject and treated it with scrupulous sincerity. The same praise may be given to Sinclair Lewis, born at Sauk Center, Minn., in 1885, for his novel *Main Street* (1920). Mrs. Mary S. Watts, born in Delaware Co., O., in 1868, wrote a series of realistic novels of American life, of which perhaps the best is the *Rise of Jennie Cushing* (1914). Henry Sydnor Harrison, born at Sewanee, Tenn., in 1880, produced one novel of unusual charm in *Queed* (1911), followed by another almost equally successful, *V. V.'s Eyes* (1913); his prolonged war service interrupted a promising career. Joseph Hergesheimer, born at Philadelphia, Pa., in 1880, won his way to the front rank of American novelists by the extraordinary beauty and distinction of his prose style; he was a master of English composition, as shown in *The Three Black Pennys* (1917) and *Java Head* (1919). Another distinguished American writer was Anne Douglas Sedgwick, born at Englewood, N.J., in 1873, who lived in Europe from childhood. Her powers, both of analysis and of style, appear to especial advantage in *The Encounter* (1914) and *The Third Window* (1920), while her short story, *Autumn Crocuses* (1919), is perhaps the best piece of fiction produced by an American under the influence of the World War. The experimental school of fiction had a representative in Theodore Dreiser, born at Terre Haute, Ind., in 1871. His first novel, *Sister Carrie* (1900), is perhaps his best.

The Drama.—From the literary point of view the drama was not important. No play of universal significance has ever been written in America, yet the work of Clyde Fitch (1865–1909) was clever and original; his best plays illustrated very well metropolitan society at the beginning of the 20th century. Augustus Thomas, born at St. Louis, Mo., in 1859, wrote many plays of western life, but his masterpiece is *The Witching Hour* (1908). Booth Tarkington produced a successful and brilliant comedy, *Clarence* (1919). George M. Cohan, born at Providence, R.I., in 1878, had an astonishingly successful career as librettist, producer and actor, which was, on the whole, marked by a steady development; his play *The Tavern* (1920) was not only original, but had distinct literary merit. Louis K. Anspacher, born at Cincinnati, O., in 1878, produced an excellent drama, both from the literary and theatrical point of view, *The Unchastened Woman* (1915). Eugene Walter, born at Cleveland, O., in 1874, showed talent for melodrama, and in one play, *The Easiest Way* (1913), for something higher. The death of Mark Twain made George Ade, born at Kentland, Ind., in 1866, the leading American humorist; his *Fables in Slang* (1900) struck a new note of humour and criticism; his plays, *The College Widow* (1904) and *Father and the Boys* (1907), exhibited a talent that the author did not choose to develop. He might have become the leading American playwright.

Poetry.—The World War had a powerful effect on the production of poetry, but a revival had set in about the year 1910, which in 1921 had shown no sign of abatement. The general interest in poetry and the immense number of young poets were notable phenomena; yet it is true that no great outstanding figure appeared—no one who for a moment could possibly rank with Poe, Emerson or Whitman. A leader in modern verse was Edwin Arlington Robinson, born at Head Tide, Me., in 1869, whose first volume appeared in 1896, but whose best work was certainly after 1910. In *The Man Against the Sky* (1916) and

The Three Taverns (1920) he combined bold, serious thinking with dignity and grace in expression. A poet who by example and precept stimulated both the love and production of poetry all over the country was Vachel Lindsay, born at Springfield, Ill., in 1879. He was the nearest modern approach to the mediaeval minstrel. He tramped many hundreds of miles, paying for lodging and meals by chanting his own verses, many of which were written for oral effect. His four volumes of poetry, *General William Booth Enters into Heaven* (1913), *The Congo* (1914), *The Chinese Nightingale* (1917) and *The Golden Whales of California* (1920), contain works of melody, colour, and imagination. Robert Frost, born at San Francisco in 1875, wrote realistic verse mainly of country life in New England, of which *North of Boston* (1914) is typical. A quiet sincerity, a sharp observation, a steady but low fire of passion and imagination characterized his work. Edgar Lee Masters, born at Garnett, Kan., in 1869, suddenly achieved fame by *Spoon River Anthology* (1915). Intellectual vigour and irony are its distinguishing features. There is a poetical epitaph for each of nearly 250 persons, each distinctly portrayed, and usually with penetrating scorn. Anna Hempstead Branch was born at New London, Conn., and was a conservative poet, writing in the traditional way with high seriousness. She had passion and imagination and was at her best in poems of home-life. Amy Lowell, born at Brookline, Mass., in 1874, was remarkable as an experimentalist. Her versatility was extraordinary. She wrote much "new" poetry in free verse and in polyphonic prose; but she was equally fine in ballads and narrative poems, written in conventional metres. Perhaps her best book is *Sword Blades and Poppy Seed* (1914). Louis Untermeyer, born in New York in 1885, wrote many graceful lyrics, translated extensively from Horace and Heine, was an admirable parodist, and compiled an anthology, *Modern American Verse* (1919), which gave a fair review of the field. Among writers of parodies and composers of light verse after the manner of Calverley should also be mentioned Franklin P. Adams, born at Chicago in 1881. One of the foremost lyrical poets was Sara Teasdale, born at St. Louis, Mo., in 1884. None of her contemporaries surpassed her in the art of pure singing. Although Henry A. Beers, born at Buffalo, N.Y., in 1847, wrote sporadic verses all his life, his best volume is *The Two Twilights* (1917) where his qualities of meditation and passion found full expression. Brian Hooker, born in New York in 1880, wrote notable sonnets and a powerful commemorative poem of the war, *A.D. 1919*. William Rose Benét, born at New York in 1886, had creative imagination, shown particularly in *Merchants from Cathay* (1918). His younger brother, Stephen Vincent Benét, born in Pennsylvania in 1898, was an extremely individualistic poet, with remarkable imaginative power, evident in *Heavens and Earth* (1920). Percy Mackaye, born in New York in 1875, published many poems and plays; his collected verse—which greatly varies in value—appeared in one large volume in 1916. Conrad Aiken, born at Savannah, Ga., in 1889, had the gift of singing speech, but his verse lacked thought. A representative volume was *Earth Triumphant* (1914). William Alexander Percy, born in Mississippi in 1885, was a lyric poet of high distinction, much influenced by classical studies. Students of free verse will find the extremes of the method represented in the works of Carl Sandburg, born at Galesburg, Ill., in 1878. His *Chicago Poems* (1916) are interesting for their local colour and aim. America lost two poets in the war, Joyce Kilmer (1886–1918), whose poem, *Trees*, seems destined to live, and Alan Seeger (1888–1916), whose posthumous volume had the stamp of genius. His lyric, *I Have a Rendezvous with Death*, was one of the most notable poems directly produced by the war. Many 20th-century poets are represented in the anthology called *The New Poetry*, edited by Harriet Monroe and Alice Henderson, published in 1917. The yearly anthology of magazine verse, chosen and edited by W. S. Braithwaite, is a fair indication of contemporary production.

In miscellaneous literature from 1910–21, the most important work in history was the continuation of the *History of the United States* by James Ford Rhodes; a contribution to the story of the development of the West was *A Son of the Middle Border* (1917) by Hamlin Garland; in scholarship, the continuation of the *Variorum Shakespeare* by the son of Horace Howard Furness; the most important and valuable biographical work was the *Life of Mark Twain* (1912) by Albert Bigelow Paine, followed in 1917 by the *Letters*; in epistolary literature the year 1920 was made memorable by the publication of the *Letters of Henry James* in the spring and those of William James in the autumn; the two best autobiographies of the period are *The Education of Henry Adams* (1918) and *The Americanisation of Edward Bok* (1920). The most important contributions to political literature were the addresses and state papers of Woodrow Wilson, President during 1913–21. In addition many books appeared dealing with various phases of the World War. Among such may be mentioned James W. Gerard, *My Four Years in Germany* (1917) and *Face to Face with Kaiserism* (1918); Bernard Baruch, *The Making of the Reparation and Economic Sections of the Treaty* (1920); Adml. William S. Sims, *The Victory at Sea* (1920); Brand Whitlock, *Belgium: a Personal Narrative* (1919); and Robert Lansing, *The Peace Negotiations* (1921). (W.L.P.)

AMERY, LEOPOLD CHARLES MAURICE STENNETT (1873–), British politician, was born at Gorakhpur, North-West Provinces, India, Nov. 22 1873, and was educated at Harrow and Balliol College, Oxford. He was elected to an All Souls fellowship in 1897, and, after travelling for a year in the Near East, in 1899 joined the staff of *The Times*. He acted as chief correspondent to that paper during the South African War, and was also editor of *The Times History of the War in South Africa*. In 1906 he stood as a Unionist and Tariff Reformer for Wolverhampton East, but was defeated, being also unsuccessful in 1908 and 1910. He was, however, elected to Parliament for Sparkbrook, Birmingham, in 1911, retaining the seat at the election of 1918. From 1914 to 1916 he served with the army, first in France and later at Salonika, but in 1917 became assistant secretary to the War Cabinet, and from 1917 to 1918 was on the personal staff of the Secretary for War. In Jan. 1919 he became Under-Secretary for the Colonies, and during Lord Milner's absence in Egypt in the winter of 1919–20 was acting secretary. In 1921 he was appointed Under-Secretary at the Admiralty.

He has published various works, including *The Problem of the Army* (1903); *Fundamental Fallacies of Free Trade* (1906); *The Great Question* (1909); *Union and Strength* (1912).

AMIR 'ALI, SEYYID (1849–), Indian jurist and Moslem leader, was born April 6 1849, of an Arab family tracing descent from the Prophet, which migrated from Persia and settled at Mohan in Oudh in the middle of the 18th century. At Hugli College, Calcutta, he graduated in 1867, proceeding to his M.A. degree a year later. Receiving a State scholarship, he came to London and was called to the bar of the Inner Temple in 1873. He had already published *A Critical Examination of the Life and Teachings of Mahomed*, the first of a series of books of Islamic modernist interpretation and apologetics which have given him a recognized place in English literature, viz. *The Spirit of Islam* (1893), *Short History of the Saracens* (1899; third ed. 1921) and *Ethics of Islam* (1893). For some years a lecturer on Mohammedan law at the Presidency College, Calcutta, and afterwards president of the Faculty of Law at the university there, his text-books on Mohammedan law and other legal works are marked by careful scholarship and characteristic lucidity. He was for some time chief presidency magistrate of Calcutta, but for the most part was engaged in practice, literature and non-official public affairs as a member of the Bengal Legislature and later of the Viceroy's Legislature until 1890, when he was appointed a judge of the Bengal High Court, being the first Mohammedan to reach the bench in India. Retiring in 1904 and settling in England, he was the first Indian to be sworn (Nov. 1909) of the Privy Council and to serve (unsalaried, but later with a small indemnity for expenses) on the Judicial Committee, where he gave the greatest assistance to his English colleagues in elucidating the intricacies of Indian law and custom. But his chief ambition in life was the advancement of the Indian Moslems, both morally

and materially, along practical and constitutional lines. While coöperating with Sir Seyyid Ahmad Khan (*see* 24.277) in overthrowing communal apathy and obscurantism as regards Western education, he deprecated his advocacy of detachment from political activity. His establishment in 1877 of the Central National Mohammedan Association, with branches throughout India, the memorial to the Government of India he promoted in 1883, and the consequent resolution of the Governor-General (Lord Dufferin) in Council in March 1885, recognizing the strength of the Moslem claims, constituted a turning-point in the history of the community, and paved the way for its fuller political organization and the reservation of Moslem seats in the legislatures under the Morley-Minto and subsequent reforms. His sustained and anxious interest in the maintenance of Moslem virility and influence throughout the world was shown by vigorous and cogent contributions to newspapers and reviews.

AMMUNITION (*see* 1.864–75).—The period of the World War witnessed important developments in the design of ammunition. Although the main effort was directed towards quantity production on a scale that no one had foreseen, and therefore to the simplification of manufacture, yet on the other hand fresh designs were constantly called for to meet changing tactical conditions. Air-fighting produced the need for "tracer" and incendiary bullets of rifle calibre and the attack of localities from the air developed the air bomb; with the free employment of thin armour-plate, armour-piercing bullets, radically different from the armour-piercing shell of artillery, became necessary; instantaneous fuzes designed to explode the shell just above ground came into general use for wire cutting; designs of grenades and trench-mortar bombs were brought out in profusion; and "chemical warfare" produced a varied ammunition which in principle was quite unlike ammunition of the customary kind.

Moreover, the needs of quantity production and in many cases the shortage of raw materials hitherto supposed to be essential to the production of projectiles and their cartridges, themselves led to novelties of design, and lastly in the attempt to increase the efficiency of older weapons brought out of the arsenals to tide over the shortage of artillery strength, the form of projectiles was revolutionized.

The subject of munitions of war collectively—the organization of the munition effort in the principal countries, with its political, social and industrial ramifications, is discussed in the article MUNITIONS. The present article deals with the technical characteristics of *Projectiles for Ordnance* (considered from the point of view of [*a*] design and purpose, [*b*] ballistic form and [*c*] manufacture); *Cartridges* (including ignition devices) and *Fuzes for Ordnance*; and *Ammunition for small arms and machine guns*. (C. F. A.)

DESIGN OF ARTILLERY PROJECTILES

The normal modern shell, whether "monobloc" or made in parts and assembled, has the general form of a cylindrical steel body, hollow to receive the filling, with the base flat and the head pointed. Formerly the head was usually shaped with an ogive struck with radii equal to two calibres, or diameters of the body, from centres on a line through the shoulders of the shell. The shape of the fuze was formerly not considered in relation to the contour of the shell; but when higher velocities were introduced, more attention was given to consideration of the contour of the fuze, as an element of the head shape, to obviating of "yaw" and to determining efficient shapes by means of experiments and empirical results derived therefrom.

In further connexion with high velocity, long range and accuracy, the shape of the head was made more pointed, being struck with radii of several calibres, though the shape did not remain truly ogival as the centres were not on the line through the shoulders of the shell. Greater range and accuracy are aimed at by making the outer contour of the rear part of the shell tapered or "stream-lined" (in America the term "boat-tailed" is used), and this again requires the head to be still more pointed, in order to compensate for loss of range due to lessened stability, since any stream-line, however small, necessitates the driving band being placed further from the base than would be the case with a cylindrical body, and the supporting surface of the shell is diminished.

Besides the true stream-lined shell, that is one with the body itself formed with a fine point and taper base, there is another class known as "false-cap" shell which was first brought into use on a larger scale in the German artillery, and in which a body of normal form, or even not of projectile form at all, is fitted with a long thin steel hood called a "false ogive" or false cap, or ballistic cap. This makes the shell in effect a 10–15 c.r.h. shell with its centre of gravity well towards the rear. During the World War this device, fitted to shells of older models, gave important increases of ranging power in all natures of forms in which it was applied, though the joint was not always strong enough or accurate enough to ensure the true centring of the projectile. The false cap is also found associated with the taper base in some cases.

Apart from ballistic efficiency, the design of a shell is largely determined by the stresses to which the projectile will be subjected on firing. The base must be of a strength sufficient to withstand the pressure of the propellant gases, and the walls of such a strength and thickness as will prevent fracture or distortion under the firing and rotating stresses.

The general trend of evolution during the war may be illustrated by comparing the characteristics of German naval shell designed before with those designed during the war. The former had thick walls and fairly small bursting charges, the head being struck with radii of less than 3 calibres and the total length being from $2\frac{1}{2}$ to $3\frac{1}{2}$ calibres. The latter on the contrary were made with thinner walls to contain a powerful bursting charge; the shape of the rear portion made stream-lined. The head was tapered to a point and usually struck with radii of 10 calibres; sometimes the head was formed by a false cap which in later types was welded to an adapter ring screwed into the shell proper. The total length was 4 to 5 calibres.

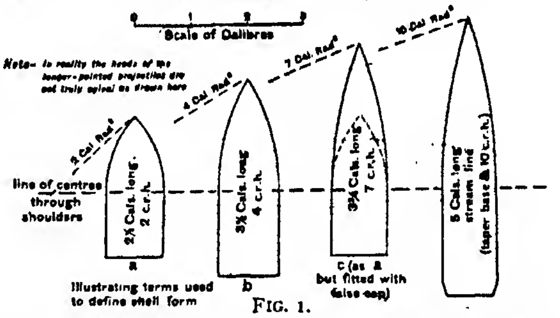

FIG. 1.

Figure 1. (which is purely diagrammatical) illustrates the general significance and relations of parts as measured in calibres.

The diameter of the body of a shell is slightly less than that of the "lands" of the rifled portion of the gun-barrel, this provides a clearance or "windage" that ensures the free passage of the shell down the gun-barrel. Pressed into a groove near the base of the shell is a band termed the rotating or driving band; it is larger in diameter than the rifled portion of the gun-barrel so that, on firing, as the projectile moves, this band taking the rifling gives the necessary spin to the shell to keep it point foremost in flight. In several instances in the German and Austrian services, two or even three driving bands have been put on to a single shell, the better to steady the shell during its passage through the bore of a gun.[1]

As a general rule the position of the band should be as near the base of the projectile as possible, it being found that the more rearward position of the band gives the most accurate shooting. On the other hand, a minimum distance of the band from the base is fixed by the minimum amount of material necessary for its support, for there is naturally a great strain thrown upon the shell when the band is forced into the grooves of the rifling and along their spiral, tending to tear off the base of the shell. Further, with stream-lined projectiles the band necessarily has to be placed far enough forward to clear the tapered base; and in Q.F. ammunition, where the projectile is carried fixed in the brass case, the band must be

[1] This is only possible of course if the twist of the rifling remains uniform; with "increasing" twist only a single driving band can be used. Fig. 10 shows three different German shells with two driving bands. (C. F. A.)

sufficiently forward to allow the projectile to be firmly secured in the case. The band must be rigidly secured to the projectile so that it will not become detached nor turn independently of the shell.

The material employed for driving bands should be soft enough for the band to be readily engraved by the rifling, even when using reduced propellant charges. Such material is of course easily dented, and as damaged driving bands lead to inaccurate shooting and increased erosion of the gun, care is necessary to ensure undamaged driving bands for service. If, on the contrary, the metal be too hard, it will throw an excessive strain on both projectile and rifling. For all these reasons copper ring, cut from a drawn tube and afterwards annealed, has been found to be the best and most suitable material. A cupro-nickel band has been employed with certain high-velocity medium guns using heavy charges. Electrolytic iron and bronze alloys have been experimented with; and during the World War, owing to the scarcity of copper, the Germans tried other metals, such as zinc and white metal alloys; and with two driving bands the upper was made of copper and the lower of zinc. The Germans also tried a novel combination in which the foundation of the band was a strip of ordinary carbon steel on which was a copper covering, the two metals being so adherent as not to be separated.

Copper bands have the drawback of causing so-called "coppering," particularly with high-velocity guns. As the projectile passes along the bore small particles of the copper band are detached and sweated on to portions of the bore of the gun; and if this surplus copper is allowed to accumulate, eventually a copper "choke" results, making that particular portion of the rifling smaller than the remainder, so that if windage is insufficient to accommodate it, either the gun must expand and bulge or the walls of the projectile set in. To get rid of copper choke it was formerly necessary to put the gun out of action and by chemical or electro-chemical processes dissipate the adhering copper. But recently it has been discovered that the copper deposit can be eliminated by using a small quantity of tin-foil between the propellant charge and the projectile; the alloy melts, being reduced to extremely fine particles which are deposited in the bore of the gun; and the tin combines with the copper to form a fusible alloy which is swept away by the next discharge. What are called "decoppering rings" have been tried attached to the shell. The Germans employed strips of alloys such as tin-lead and zinc-aluminium pressed into a groove round the shell.[1] Decoppering charges or rings would be employed after the gun has been warmed by firing; and the gun must be absolutely free from grease or graphite material.

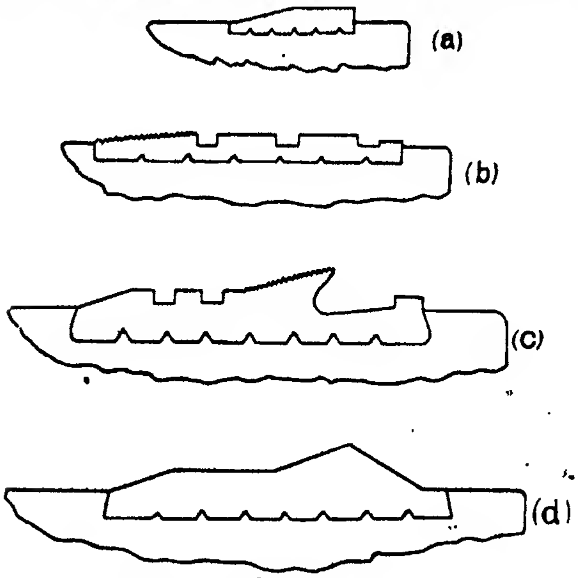

FIG. 2.

Generally the design of driving band as used by European continental powers, is a narrow strip somewhat rounded on top. In the British service the band is of a more elaborate shape. The first form of band (fig. 2, *a*) was narrow, flat on top and with a front slope so as easily to take the rifling, but excessive fringing of the copper caused the introduction of a broader and shallower band (*b*) with cannelures cut in it to receive any stripped copper. As this shallow band was found not to grip sufficiently with worn guns, a band with a gas-check (*c*) was introduced, in which an undercut lip was formed on an increased diameter towards the rear part of the band; this lip was readily expanded on firing and formed an effective seal for the gas. For modern heavy high-velocity guns, driving bands with a greater body of metal are found necessary so as to give a better grip to the rifling; in such designs (*d*) a raised hump of metal is placed near the rear of the band. Before the war the tendency with medium types of guns was to have a broad band with but small depth of metal between the highest point of the band and the line of the shell; but this was modified during the war period in order to save copper, and to keep worn guns longer in use, by using a very narrow band of increased thickness.

In addition to the ordinary driving band, a band round the shoulders of a shell is sometimes used as a forward centring band to steady the projectile while passing through the bore of a gun. This band would not be of such a thickness as to be engraved by the rifling. The same result is obtained in many designs (see fig. 5a) by swelling out the metal of the shell to a distinct shoulder, sometimes known as a *bourrelet*. It requires, however, very accurate machining of the shell body at this point, and, probably for this reason, the use of a steadying band is more favoured on the continent of Europe.[2]

The weight of a shell is, to a certain extent, limited by its length and the stresses permissible on gun and carriage. With certain guns projectiles of different weights are used, and, provided that the difference in weight is not excessive, such shell when fired under similar conditions will have, at the muzzle of the gun, approximately equal energies, though they will range differently.

With different types of shell fired from the same gun, there must be a difference in length, to ensure that the weight of all the shell is the same. To ensure accurate shooting the shortest shell should be not less than two calibres in length; while on the other hand a very long shell introduces difficulties as it necessitates a sharper twist of rifling in the gun to give the requisite rotation, and thus imposes a greater strain on the gun. A very successful German shell for a light field howitzer was about 4½ calibres in length with centre of gravity about 1⅔ calibres from the base; had the head struck with about 4½ calibre radius; was stream-lined and weighed about 35 lbs.[3]

All modern shell are prepared to take a fuze for igniting the explosive in the shell (Sect. III. b.). Pointed shell (such as those intended for armour-piercing) for which the head must be retained intact, are fitted with base fuzes; other shell have the heads truncated and fitted to take nose fuzes. In addition to the fuze a "tracer" is sometimes employed in order to mark the trajectory while the shell is in flight. For night use, the tracer shows a luminous spark, for day use the tracer gives a smoky trail.

The natures of shell now used are:—(*a*) high-explosive, (*b*) shrapnel, (*c*) armour-piercing, (*d*) special shell of kinds such as smoke, star (illuminating), gas and incendiary.

(*a*) *A high-explosive shell* may be looked upon as a travelling mine, containing a large disruptive charge of high explosive. To obtain satisfactory results there must be full and complete detonation of the high-explosive bursting charge within the shell, otherwise the general effect will be small.

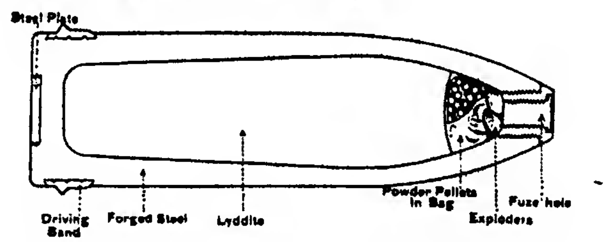

FIG. 3.

The body (fig. 3) is normally of forged steel with a solid base; a special steel plate is fitted in a recess in the base; and a socket screwed into the head, or the head itself is threaded to take a fuze which completes the point of the shell. If the shell body be of considerable thickness the explosive content is reduced; but on the other hand the shell body is stronger and there is thick metal for man-killing splinters. A thin-walled shell with a maximum explosive content on the other hand is adapted for the attack of material; with an instantaneous fuze it is useful for clearing ground of obstacles such as wire entanglements, and,

[1] Such decoppering rings will be seen in fig. 10 below the lower driving band in (*b*) and (*c*). (C. F. A.)

[2] A German shell with a steadying band is illustrated in fig. 10 (*a*). (C. F. A.)

[3] A useful approximate rule for comparing the weights of shells of different guns (similarity of shape being presumed) is:—half the cube of the calibre in inches is the weight in pounds. By this rule the weight of the shell just mentioned would be 34·5 lb. and that of a similar 5·9-in. shell would be 103 lb. (C. F. A.)

with a delay action, for the attack of buildings or dugouts. (A German example is shown in fig. 4.)

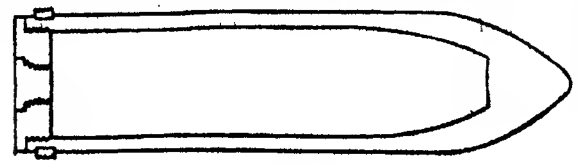

FIG. 4.

In the British service the explosives in general use for high-explosive shell are T.N.T. (tri-nitro-toluene, or trotyl), a mixture of ammonium nitrate and T.N.T. known as amatol, and mixed in different proportions, and picric acid (lyddite). These explosives, especially amatol, are, under proper filling conditions, inert and safe substances, as they have to be if they are to sustain the shock of discharge from the gun. To ensure the necessary complete detonation therefore, an "exploder"[1] —in principle a small charge of less inert explosive—is interposed between the fuze and the bursting charge proper.

The British method of inserting the bursting charge is by melting the explosive in a hot-air chamber and pouring it, in liquid form, through a funnel into the shell. Filling through the base seems to be in favour in Germany; and the general method of filling is with one or more blocks of cast, or pressed, explosive enclosed in containers of varnished cardboard, linen or paper; a more uniform density of burster can thus be obtained. In some German H.E. shell the bursting charge is separated into two portions by a diaphragm which is pierced with holes for communication between the two charges. In every case a cavity is made in the centre of the filling, nearest the fuze, to receive the exploder which, being detonated through the medium of the fuze, in turn detonates the filling of the shell. Sometimes the relay element interposed between fuze and main bursting charge is contained in a "gaine" screwed to the fuse itself; the metal walls of the gaine confine the contents long enough to secure a good detonation and so a sufficient shock to the main charge. Between gaine and charge, if there is room, a small exploder is inserted to make contact intimate and the propagation of the shock more certain.

With 80/20 amatol, which in complete detonation gives practically no smoke effect, some smoke-producing mixture is included in the filled shell to assist observation.

The bursting charges for German H.E. shells are principally amatol of a mixture 13 to 87; frequently they are of trotyl; and dinitrobenzene and tri-nitro-anisol have been used. Ammonal[2] and "ekrasit" have been used in Austria. With the German 17-cm. H.E. shell the explosive is trotyl stemmed in two containers, the exploder cavity being formed in the upper portion in which a brass exploder container is placed; with the 24-cm. H.E. shell two exploders are used.

A typical high-explosive shell is shown in fig. 5; the steel body is stout, giving great strength and thick metal for fragmentation; the amatol filling is in the form of blocks; the centre block is of T.N.T. which when acted on by the fuze and exploder, facilitates detonation and gives smoke to assist observation of fire.

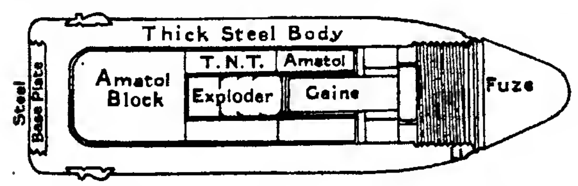

FIG. 5.

(b) *Shrapnel shell* is essentially a man-killing projectile; but shrapnel was employed during the World War for wire-cutting and for long-range fire against observation balloons. In order to get as many bullets as possible to be packed into the shell, the walls are made as thin as is consistent with the shell body being able to withstand the firing and rotational stresses which act on it in the gun and during flight. With shrapnel fire, the normal practice is to open the shell in the air so as to release the bullets in a compact mass, their velocity at the moment of release being slightly accelerated by a small opening charge of gunpowder placed in a recess in the base of the shell below the bullets. To ensure the ready release of the bullets it is necessary to have either a separate and lightly attached head (in the heavier shell such as that in fig. 6), or a fuze socket held not too securely (in the lighter types fig. 5a), so that on the ignition of the small gunpowder charge in the shell, the head or the fuze-socket is readily blown clear and does not impede the release of the bullets.

The effect of a shrapnel shell depends on both the weight of the individual bullet and the number of bullets. To obtain high-striking energy—or rather to ensure a great depth of effect (this being defined by the point of burst of the shell and the point at which the released bullet ceases to possess adequate striking power)—the weight of each bullet should be kept as large as possible by the use of a heavy metal, viz. lead, hardened by an addition of antimony. The Germans used steel shrapnel bullets in some cases. On the other hand the larger the bullets the fewer of them a given shell will contain. The best compromise is obtained by making the bullets spherical and of a heavy metal. The bullets for British light field shrapnel run 41 to the lb., and for heavy field shrapnel 35 to the lb.; in special cases much heavier bullets are used.

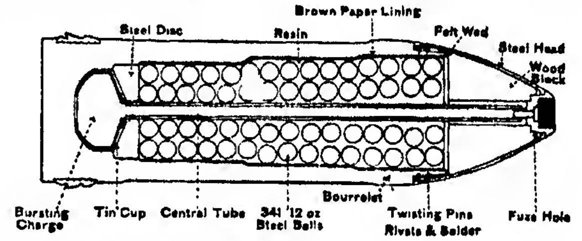

FIG. 5a.

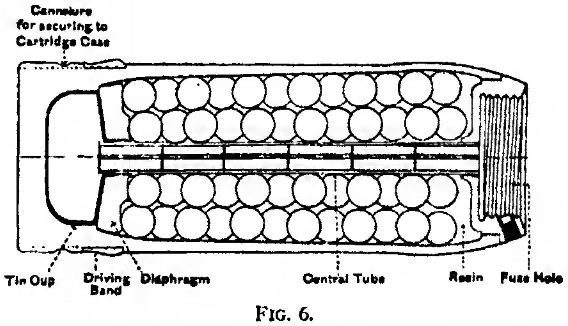

FIG. 6.

The shell consists in a light hollow steel body of which the walls increase in thickness slightly from the top to the base, near which the shell cavity contracts to form a ledge for the steel disc or diaphragm to rest on, and a chamber for the opening charge. The opening charge is usually of fine grain gunpowder[3] whose function is to force off the head or blow out the fuze socket with fuze, and drive out the bullets, which are thus carried forward with slightly accelerated speed as compared with the remaining velocity of the shell. The opening charge is placed in a tinned sheet-iron "cup" inserted in the recess in the base of the shell; the object of this "cup" being to prevent dangerous friction between the gunpowder and the rough interior of the shell. Resting on the shoulder above the tin cup is a steel disc, or diaphragm, which is screwed to receive a brass tube which occupies the centre of the shell. This diaphragm

[1] With lyddite fillings the exploder system takes the form of a bag of picric powder inserted in the cavity in the filling; the picric powder is readily ignited by a gunpowder-filled fuze and burns rapidly to detonation. With the other high-explosive fillings, particularly amatol which is difficult to detonate, the exploder is T.N.T. in crystalline form, inserted in small bags or cartons. Pellet exploders may probably take the place of exploder bags and cartons so as to give still more intimate contact between fuze and exploder. With T.N.T. exploders, as gunpowder-filled fuzes are not suitable, a detonating or high-explosive-filled fuze is employed.

[2] Ammonal was employed in the British service for trench-mortar bombs and for grenades, but not for artillery shell proper.

(C. F. A.)

[3] A compressed pellet of gunpowder has been tried instead of loose fine grain gunpowder, with the idea of increasing the driving power of the charge and therefore the velocity of the bullets, or alternatively of reducing the necessary space for the driving charge, and so gaining space for more bullets. Compressed powder charges, however, entail a separate base and lead to complications and undue expense.

supports the weight of the bullets, and prevents the bullets setting back on the shock of firing and crushing in the tin cup, and possibly exploding the gunpowder. In some cases the central tube is filled with gunpowder pellets, which by burning, increase the cone of dispersion of the bullets and give more smoke, which is exceedingly important for the observation of bursts in air. The interior of the shell is fitted with bullets set in resin, which, besides holding the bullets firmly, is ignited by the opening charge and so increases the smoke effect. The interiors of some shells are lined with brown paper in order to prevent the resin from adhering too firmly to the body of the shell.

The mouth of the shell is closed by a metal socket threaded for the reception of a fuze; the top end of the central tube is soldered to this fuze socket. When the gunpowder charge in the shell is exploded by a flash from the fuze down the central tube, the bullets are projected from the case to travel forward along the line of flight within a cone of small apex angle. The bodies of shrapnel are not intended to break up when the opening charge is exploded, but merely to act as containers to convey the bullets to the point of burst.

Another type of elongated shrapnel shell was formerly in use in which the burster was contained in the head. In this the head was firmly and the base very lightly attached to the body, so that on the explosion of the opening charge, the head and body remaining together were drawn over the bullets, and falling to the ground allowed the bullets to proceed on their course and scatter. In this pattern more bullets could be packed into a shell, owing to the elimination of the diaphragm and central tube; but instead of the closely grouped forward shower of bullets produced by the base burster, there was an open scattering of bullets, due to the checking, negative, effect of the opening charge on the bullets.

Normally field guns fire both high-explosive and shrapnel shell. Many attempts have been made to provide a "universal shell" which would combine the functions of both types. If the bullets of a shrapnel shell be packed in some high explosive instead of resin, then, on the time fuze igniting the base opening charge, the shell would open in the ordinary way, the high explosive (which as has already been shown is difficult to detonate) merely burning and giving useful smoke. But if a gaine, ignited only by the percussion portion of the fuze, be provided to act on some high explosive in the head of the fuze, then the whole of the high explosive, detonating on impact, would probably produce sufficient disruptive violence to shatter the whole of the shell and destroy material.

The Germans in the World War employed a type of universal shell having a high-explosive filling in the head, with the fuze so arranged that when the shell is required to burst in air, the head of the shell is blown off bodily, flies forward with the bullets, and itself bursts when striking the ground. If, on the other hand the whole shell is burst on impact, the disruptive effect of the high explosive in which the bullets are packed[1] breaks up the shell.

The Austrian universal shell is somewhat similar. These shell can be used in four ways, as a percussion H.E. without or with delay action, as a time shrapnel, and as a time H.E. The fuze is designed accordingly.

With the universal shell, there is a distinct loss of bullet capacity, with a consequent loss of shrapnel efficiency. It is therefore considered, in some services, more practical and effective to carry two types of shell, high-explosive and shrapnel, and use them according to tactical requirements, than to attempt the complications in design and manufacture, mistakes and possibly failures in the field, entailed by the use of a type of universal projectile.[2]

(*c*) *Armour-piercing projectiles* for maximum penetration, should be tempered so as to break rather than set up sensibly, and the stresses in the way of perforation and of fracture should be clearly distinguished. The main question is that of the striking energy modified by the projectile's power of holding together, which depends directly on the tenacity of the metal; and the capacity for taking a bursting charge would be of less importance than the strength of the head and walls. It appears probable, however, that the ultimate tenacity, as well as the limit of elasticity, would be the measure of the projectile's power. In direct impact, on deformation commencing, all penetration comes quickly to an end; but after commencing an injury, any following up of the blow at the exact spot acts in so forcible a way that between the limit of elasticity and that of ultimate tenacity, a sensible amount of work must exist. Generally with projectiles for attack of soft armour, hardness is a necessity, and for attack of hard armour, tenacity is a necessity.

Armour-piercing projectiles may be divided into two classes. First come armour-piercing shell (fig. 7), in which the bursting charge is comparatively small, the head and point extremely hard, and the body softer to give greater tenacity. The success of the old Palliser projectiles depended upon the metal used, the mode of casting, and the form of the projectile and distribution of the metal. With regard to these points specially selected iron was used; the projectiles were cast head down (to ensure density and soundness) in an iron chill with the result that the molten metal rapidly solidified and the qualities given to the head by white iron were intense hardness and crushing strength, but considerable brittleness; the form of the head was a fairly long elongated point, and the object in manufacture was to get the metal as far forward as possible so as to impress its momentum on the armour without acting through the medium of the walls of the shell, though the latter were necessarily thick; this method of manufacture obviously diminished the interior capacity and consequently the bursting charge of the shell.

As processes for hardening armour came to be introduced and used, the material for armour-piercing shell was necessarily changed to steel.

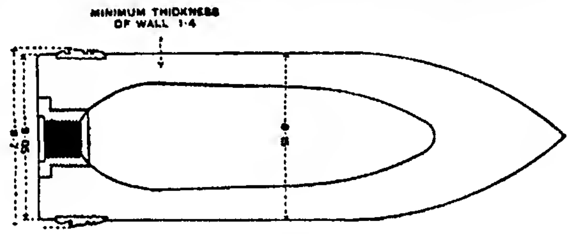

FIG. 7.

Owing to the liability to split spontaneously, due to the strains set up during the hardening process, the shell are stored for several months before being filled, and the bursting charge is contained in a thin aluminium container. The base is removable and a base adapter is fitted, the base being further secured by a copper gas-check plate, steel plate cover, and steel locking ring screwed to the adapter.

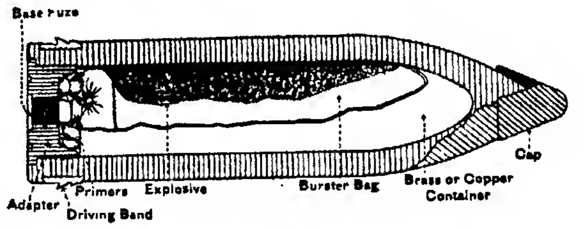

FIG. 8.

Secondly, there are semi-armour-piercing shell (fig. 8), which are practically common shell pointed, designed to effect a certain amount of penetration of light armour, and to contain a large bursting charge. The points are specially hardened, in some cases capped (as in fig. 9) and the bursting charge is held in a metal container.

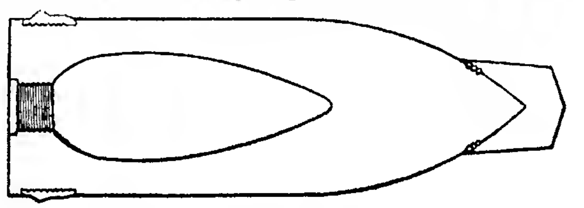

FIG. 9.

Hard-faced armour defeats a projectile simply by fracture of the point and such fracture can in a great measure be prevented by a cap which protects the point when it meets the hard skin of the armour, whether the cap be hard and shattered or soft and crushed.

The first introduction of a cap was to allow a projectile to bite armour obliquely; but it is the value of a cap as a support to the point of the shell that has determined its use. Formerly the shapes of caps were designed without any consideration of the contour of

[1] This packing of the shrapnel bullets in H.E. is not an inseparable element of the design. In some universal shell, the ordinary resin or other non-explosive material is used. (C. F. A.)

[2] According to Schwarte (*Militärische Lehren des Grossen Krieges*) the German pattern of universal shell proved very disappointing in war; on the other hand the Austrian and other "Orisanz-Schrapnell" shell based on Ehrhardt design were most successful. (C. F. A.)

the shell; but in all recent types the cap is made to conform to the contour of the head of the shell. The use of the ogival radius determines the breadth across the front of the cap, while a certain thickness through the point is required to give satisfactory armour-piercing qualities, and the combined effect of these two dimensions prevents any appreciable reduction in the weight of the cap. The use of a cap introduces a serious disadvantage in that extra weight is put into the head, whereas the heavier part of a shell should be the base. The cap is attached to the head of the shell by notches in the shell or by interrupted ribs. The sheath of the cap may require to be built up from two or more pieces; and with heavy shell the cap may be in four pieces. (F. M. R.)

Fig. 10, showing typical outlines of German shell, taken from the *German Heavy-Artillery Ammunition Handbook* of 1917, may be of interest as illustrating the tendencies of design discussed above. Here (*a*) shows the old-fashioned 2 c.r.h. shell, with a front steady-

ing band of copper; (*b*) shows a false-cap shell without stream-lined base; (*c*) shows a stream-lined shell proper. (C. F. A.)

PROJECTILE FORM

The general form of the elongated projectile in use for many years prior to the World War is illustrated in fig. 1. The body

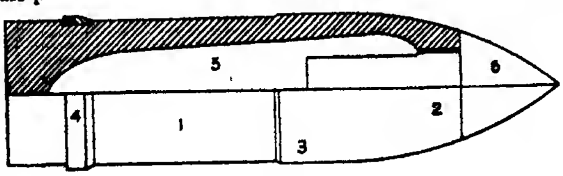

FIG. 1.

(1) is cylindrical in form and of uniform diameter except that the "bourrelet" or shoulder swell (3), intended to form a bearing on the lands of the gun, is slightly larger in diameter.[1] Special care is taken in accurately machining this bourrelet, and the average amount by which the diameter of the bourrelet is less than that of the gun is 1/1000 of the calibre.

It was the usual practice for many years to make the head (2) of ogival shape, with the centre of the circular arc in or near the plane of the front end of the body and with a radius of arc varying from $1^1/_2$ to $2^1/_2$ calibres. When a point fuze was used, as illustrated in fig. 1, its projecting end was sometimes, but not by any means always, made to conform to the shape of the head.

The rotating band (4) was placed at a distance of from $^1/_{12}$ to 1 calibre from the base, and its width was from $^1/_6$ to $^1/_3$ calibre. In addition to engaging the rifling in the gun and so causing the rotation of the projectile, other functions of the rotating band are to provide a rear bearing for the projectile, to provide a definite seating for the projectile in loading, and to prevent the undue escape of powder gas around the projectile when the gun is fired.

[1] In many shells this bourrelet does not appear, the walls remaining uniform from the driving band to the beginning of the head. In these cases a slight outward splay is given to the upper part. (C. F. A.)

In fig. 1, which illustrates a field projectile, the shell cavity is either cylindrical or larger in diameter toward the front end of the body, and the fuze is at the point.

In naval or coast-defence projectiles, where penetration of armour is desired, the general form is as illustrated in fig. 2.

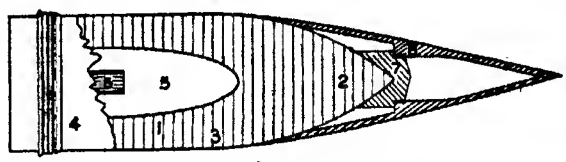

FIG. 2.

The great shock to which the projectile is subjected on impact with armour requires thickening of the walls at the forward end and shortening of the cavity. For the same reason the fuze can no longer be placed in the point but must be placed in the base. It is found that armour-piercing properties are improved by adding a soft metal cap (7) to the hard head (2). In order to get a smooth form of head, a hollow "false ogive" (8) was added to the forward end of the cap.

Experiments to Improve Form.—Previously to 1900, bullets for small arms had rounded points and "square" bases. Experiments started about that time in Russia indicated that a marked improvement could be obtained in flatness of trajectory and this improvement opened the way for experiments in all countries to determine forms of artillery projectiles that would give increased ranges (or, for similar ranges, flatter angles of descent and higher terminal velocities). At that period (about 1907) the mounting of high-power ordnance, both field and naval, did not usually permit of elevations in excess of 20 degrees. There was a possibility of increasing ranges by modifying existing mounts or building new ones, but such a proceeding would have been expensive, and, as will be shown, might not in many cases have increased the range as much as the use of an improved projectile with the old elevation.

Early Improvements in Head.—Even before the adoption of sharp-pointed bullets in small arms, Petrovitch, a Russian, had about 1902 brought out a mathematical discussion of the form of surface which would encounter the least resistance in passing through an elastic medium. This paper helped to encourage experiments to improve the form of head. Firings were made in the United States in 1907 from a 6-in. gun with a 106-lb. projectile having a tangent ogive of 7 calibres radius, using a muzzle velocity of approximately 3,050 ft. per second. The outline of this projectile is shown in fig. 3.

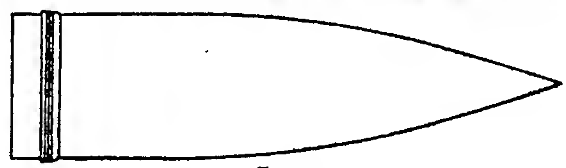

FIG. 3.

The range obtained was 12,800 yd. at an angle of elevation of 7°, as against 7,800 yd. obtained with the same weight of projectile with a 2-calibre radius and fitted with an armour-piercing cap as shown in fig. 2, without the false ogive. The muzzle velocity with the latter projectile was 2,990 ft. per second. This increase in range of 60% led to other experiments. As it was desired, however, to retain the armour-penetrating efficiency of these projectiles, attention was principally given to the design of a form of head and cap which would make the projectile efficient both for armour penetration and for range.

Firings were made with the same projectile having the point rounded off, as shown in the following table, which gives the corresponding range and coefficient of form:

Radius of Point In.	Range Yd.	Coefficient of Form
0·75	12,920	·505
1·25	11,940	·600
1·75	10,730	·762

It was supposed by some, at that time, that the air resistance was principally dependent upon the form of junction of head and body; that little additional resistance would arise if the sharp point was rounded off; and that the rounded form of point would add to the efficiency of the projectile in armour-piercing. The firings indicated a marked effect on range of even a slight rounding of the point. Armour-piercing projectiles of the form shown in fig. 3 did not seem

to stand up under the impact as well as those of the older form. But by the addition to the older (2 c.r.h.) projectile of a special cap and false ogive, it was found that not only could the excellent ballistic properties of the 7-calibre radius ogive be retained but, on account of the support given by the special cap, the armour-piercing ability of the projectile was increased. Similar experiments with 12-in. projectiles gave the following increases in ranges of the projectiles with 7-calibre ogives over those with 2-calibre ogives and blunt caps. The muzzle velocity was about 2,250 ft. per second.

Projectile	Ranges		
	1st series	2nd series	3rd series
	Yd.	Yd.	Yd.
Long Point . . .	5,365	8,900	13,800
Blunt Cap . . .	5,020	8,000	11,900
Difference. . . .	345	900	1,900
Percentage increase.	6·8	11·3	16·0

It is to be noticed that the advantage of the long sharp-pointed head increases with the range.

Similar tests made in France, England and Germany, with heads as long as 9-calibre radius ogive, left no doubt that a very substantial increase in range could be obtained by increasing the sharpness of the point through use of a longer head. As has been pointed out, the importance of this fact was not fully appreciated until the necessity arrived of obtaining extreme ranges from all guns. When full advantage had been taken of increasing muzzle velocities to the limit of the ability of the guns to withstand the necessary pressures, and means, sometimes improvised, had been used to permit the guns to be fired at the elevation corresponding to the maximum range, there remained only improvement in the projectile to further increase the range.

False Ogives.—The hollow extension of the head covering the fuze of field projectiles or the armour-piercing cap of armour-piercing projectiles is called a false ogive.[1] Its use was first suggested in America in 1907 by Capt. W. A. Phillips as an extension for the blunt cap of armour-piercing projectiles. Apart from its effect in lengthening and sharpening the head, and thus increasing the range, no ballistic advantage was claimed for it. Its use with an A.P. projectile is shown in fig. 2. As applied to field shell the false ogive covers the end of the fuze. It is desirable to make the cavity of the shell as large as possible, and so the walls of the shell proper are run forward as far as they can be, and still permit a tap for the fuze of proper size at the front. The head is then completed by screwing the false ogive over the fuze (see fig. 4).

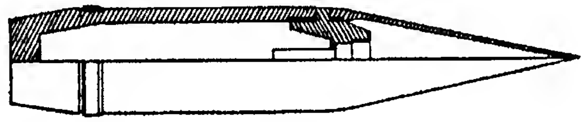

FIG. 4.

The use of a light false ogive throws the centre of gravity backward with respect to the centre of form. This is found to be of advantage in point of ranging power, providing the somewhat greater tendency to initial yaw is sufficiently counterbalanced by increased spin.

Improvements in Form of Base.—Experiments to determine the best form of base commenced soon after these remarkable improvements in range by changes in the head were obtained. In experiments made in 1913 with a 6-pr. gun use was made of ogival and tapered bases coming to a point, the total length of base from the start of the taper being 1 calibre or less.

The resulting ranges were generally less than those of the square-based projectile of otherwise similar form and weight, and they were less accurate. Bases of 1-calibre length tapered to a cone of 9° were then tried, but seemed to give no better results than the square base. In both these experiments the projectiles had ogival heads of 2-calibre radius. Experiments made in 1915 with 6-in. projectiles of the three forms of base shown in fig. 5, fired with a muzzle velocity of 2,675 ft. per second, at an angle of elevation of 5°, gave the following results:—

Form of Base	Mean Range	Mean Dispersion	
		Range	Deflection
	Yd.	Yd.	Yd.
A	8,200	88	9
B	8,440	41	7
C	8,410	52	6

A small increase in range and greater accuracy is shown by the boat-tailed projectiles.

French experiments made in 1914 demonstrated that the form of base to give the best result with any projectile is dependent upon the form of head used, and vice versa. A similar conclusion had been reached elsewhere.

[1] Known also as the ballistic cap or "false cap."

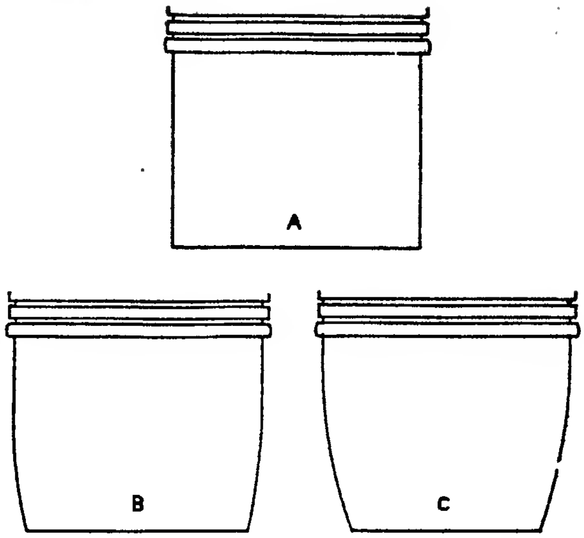

FIG. 5.

Influence of Velocity.—By comparing maximum ranges obtained with various projectiles and velocities with ranges *in vacuo*, we may obtain a good idea of possible improvements in projectiles.

Fig. 6 shows vacuum range as a function of velocity plotted to a logarithmic scale, together with other lines showing fractional parts of the vacuum range and points showing the maximum ranges of actual guns. The ranges of low-velocity guns fall near the vacuum line, while those of high-velocity guns are much farther away.[2]

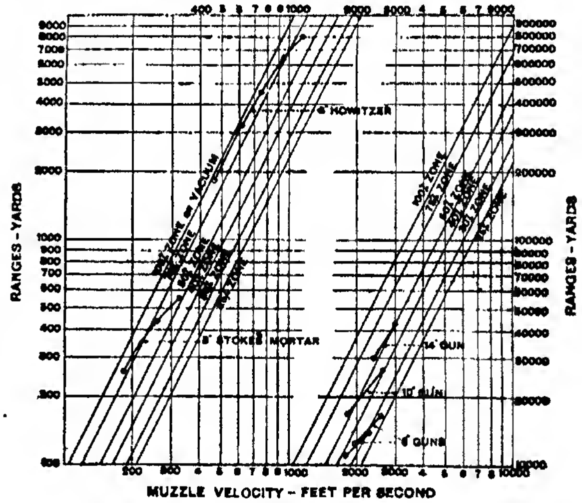

FIG. 6.

The possible improvement in projectiles to be fired from low-velocity guns is, therefore, very much less than in those fired from high-velocity guns. Actual trials show that within reasonable limits neither the form of the head nor that of the base has an important influence on maximum range or accuracy when the velocity is less than 1,200 ft. per second.

Improvements in Rotating Bands.—Although the rotating band has performed all its useful functions by the time the projectile has left the gun, it still has to be reckoned with, since it is capable, if improperly designed or located, of materially reducing the range and increasing the dispersion. If it has a "lip" (called in Great Britain "gas check") or is thick at the rear, the excess metal will be wiped back on the passage of the projectile through the bore and will form a ragged extension; and when the projectile is free the centrifugal force due to its rotation may be enough to cause this extension to

[2] Explanation of fig. 6.—Abscissae show velocities in f/s, ordinates ranges in yd., oblique lines the % of theoretical vacuum range obtained in practice. Thus the 10-in. gun, which obtains a range of 26,500 yd. with a m.v. of 2,600 f/s in actual practice, would obtain with the same velocity one of 63,000 *in vacuo*. 26,500 is 42% of 63,000 and the projectile is therefore spotted between the 40% and the 50% lines.

stand out perpendicularly to the projectile and thus immensely increase the air resistance. Conditions are not improved by the partial breaking-off of this extension or by its incomplete formation in the gun. It is just this irregular form and size of this extension or "fringing" of the rotating band which makes it a possible source of great inaccuracy. Whether fringing actually takes place depends not only on the design of the band but also on the velocity of rotation of the projectile and the thinness and length of the extension formed at the rear of the band. By taking all these points into consideration it is possible to make a design which will give no trouble from fringing. But, apart from the effect of fringing, the rotating band may materially increase the resistance if improperly located. While it is desirable from other considerations to have the rotating band as near to the base of the projectile as possible, it is found that a better position for range and accuracy, even if a square-based projectile is used, is $^1/_2$ calibre or more from the base. Similarly, if a boat-tailed base is used, the range and accuracy are both reduced if the band is placed just at the beginning of the taper. It should be at least 1/8 calibre forward of this position.

Double and even triple rotating bands close together at the rear are sometimes used, the idea being that this construction will make the band more efficient as a gas check and that fringing is less marked than for a single rotating of the necessary width. Bands near the bourrelet have also been used. A more recent development is the use of a copper bearing band at the bourrelet.

Optimum Weight of Projectile.—The question of the weight of projectile to be used with a gun of a given calibre frequently arises. Other considerations besides that of ballistics affect the answer. There is a practicable limit to the pitch of rifling, which has been fixed at about one turn in 15 calibres for low-powered guns, and one turn in 20 calibres for higher-powered guns. With some such limit in pitch of rifling, projectiles cannot be made more than about 5 calibres in total length and retain the necessary factor of stability in flight. There is thus formed a certain upper limit of length and weight. If the projectile is shortened below this limit and the weight reduced, we may assume that, with the use of a suitably quicker powder, the same muzzle energy and consequently a higher muzzle velocity may be obtained; but while the higher muzzle velocity would tend to increase the range, the smaller weight and ballistic coefficient would tend to reduce it. It is evident that for each gun there is some weight of the projectile, called the "optimum" weight, which will give the greatest range, assuming the muzzle-energy constant.

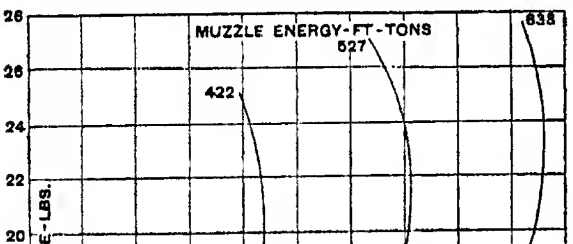

FIG. 7.

The weights of similar projectiles vary with the cube of the calibre. Similar projectiles for different calibres, being the same length in calibres, are of equal stability providing the pitch of rifling is the same. The weights of the optimum projectiles vary about with the square of the calibre, if based on uniform muzzle velocities in different calibres. For high-powered guns of calibres roughly below 5 in. the optimum weight is greater than the usually accepted weight based on similarity, and for larger calibres it is less. The optimum weight of projectile for any gun and muzzle velocity may be readily worked out by the methods of exterior ballistics, by assuming several different weights of projectiles and working out the maximum ranges on the basis of equal muzzle energies. Fig. 7 illustrates the maximum ranges to be expected from a 75-mm. gun under the assumption of equal muzzle energies. It is to be noted that the optimum weight increases with the muzzle energy and that the range changes only slowly as we pass from the optimum weight. In the case of large-calibre naval or coast-defence guns a reduction in weight of projectile tends toward optimum, that is, toward increase in range; but the reduced weight and increased velocity of the projectile lead to greater losses of energy in flight, resulting in a smaller striking energy at a given range. (W. H. T.)

MANUFACTURE OF SHELL

The material of which a projectile may be made depends largely on the functions required of it.

Cast iron is brittle, more or less hard, with low elasticity, practically no ductility, and low tenacity; consequently this material is of no value for a shell which is required to do heavy work at the end of its flight or to promote a good explosive effect, and is somewhat risky when required to stand the shock of discharge from a high-velocity gun. Cast iron, however, is fusible and easily worked, and therefore cheap; it is consequently sometimes used for practice shot with reduced propellant charges. In the World War it was used for certain chemical shell where the chemical content was liable to attack steel, and—especially by the Germans—as a substitute for steel when the latter could not be had in sufficient quantities; but its use for projectiles is almost entirely confined to such. *Wrought iron* has a fair tenacity and a good ductility, but it is quite superseded by steel which can be manufactured as easily and cheaply.

Steel possesses the characteristics of elasticity, ductility and tenacity, and is sufficiently hard to enable it to withstand the stresses and shocks a modern projectile is required to sustain. Forged steel[1] is fibrous in molecular structure, and is improved by forging, which increases the tensile strength and minimizes the chance of porous metal remaining; the more work put into the forging, the better the quality of the finished material as measured by its tensile strength in the direction of the forging. Cast steel is crystalline in molecular structure and much harder than forged steel and has less ductility and tenacity; it must always be annealed after it has been allowed to cool after casting, in order to dissipate the uneven molecular stresses set up during cooling. In the case of steel for projectiles the composition includes from 0·35% to 0·7% of carbon and small percentages of nickel, manganese, and silicon. With cast steel, the walls of a shell cannot be so thin as with forged steel because the material is not so good and there always is a risk of blow-holes and porous metal being present.

The chemical composition of the steel for shells is generally as follows:—

	Composition: Per cent		
	H.E. Shell	Shrapnel	Armour-piercing Shell (†)
Carbon . . .	0·5	0·75	0·5 to 0.75
Silicon . . .	0·35	0·3	0·5
Manganese . .	0·4 to 1·0	1·0	1·25
Sulphur* . .	0·08	0·04	0·08
Phosphorus* .	0·08	0·06	0·08
Tensile strength .	35·49 tons /in²	(Light shr.) 56 tons /in.² (Heavy do.) 38 tons /in.²	38 tons/in.²
Yield point . .	19 tons	(Light shr.) 36 tons (Heavy do.) 24 tons	24 tons

* The sulphur and phosphorus are deleterious and should be as low as possible.

† Steel for A.P. shell should have a higher percentage of carbon in order to give harder material.

[1] The term "forged steel" is still used but the process of forging under a hammer has been discontinued for some time, the hydraulic press being used instead. The hydraulic press is said to work the mass more uniformly than does the hammer, while hollow-forging on a mandril has the same advantage over solid-forging. Forging should cease at a temperature of about 1,200° F., for if continued below this temperature, the metal tends to become "hammer hard" and internal strains are introduced.

H.E. shell are always made of forged steel; they have coned walls, thicker at the base to give better strength to the shell. The body requires to be as strong as possible so as not to break up too readily and thus lose the value of the pressure set up on detonation; also, unless the best steel is used the body is pulverized instead of breaking up into pieces of a size to form effective missiles. Pointed shell, whose general use is for the attack of armour plate, require to be especially tough and strong.

Common shell have been made of cast iron, cast steel, and forged steel; a disadvantage with forged steel is that, with a bursting charge of gunpowder, the shell breaks up into a small number of fragments; the stronger the material, the thinner can the walls be made, and hence the larger the bursting charge.

Shrapnel shell are generally made of forged steel, though in some larger natures they have been made of cast iron. The steel is required to have a high yield point and breaking stress, as this is essential in order that the body, which is made as thin as possible to provide a maximum capacity for the bullets and opening charge, may be able to withstand the pressures set up on the shock of discharge from the gun.

A.P. shell are made of either cast steel or forged steel; the points are made extremely hard, and the bodies softer; great thickness of metal is worked into the head, and the walls are made thicker than in other shell.

The steel for projectiles is made by different methods: (1.) *Crucible*, which is largely used on the continent of Europe, particularly in Germany. With this method there is difficulty in obtaining uniform quality. (2.) *Bessemer*, which does not lend itself to the careful control necessary for production of the steel suitable, though the method is rapid and cheap. (3.) *Open hearth.* The acid process is preferred to the basic as more suited for production of steel of uniform quality, and more economical. As it does not remove the phosphorus, a purer pig-iron must be used.

The manufacture of H.E. shell (other than solid-pointed) is carried out in a hydraulic press. The cast-steel ingot is heated up and punched, care being taken to ensure a central cavity in the forging; for larger shell several punches or drawings, with intermediate heatings, may be necessary to produce the required dimensions. The forging is then oil-hardened by heating up to a specified temperature and quenching in oil. Analytical and mechanical tests are next applied to samples and, if satisfactory, the forgings are sent to the machine shop for machining and centring. The shell are then heated to a dull red heat for the purpose of "heading" or "bottling" to give the required ogive to the head; this is carried out by forcing the head of the shell into a die by hydraulic pressure, and can be done cold, but cracks are liable to occur at the shoulders on account of the internal stresses. For "bottling" larger shell, it is sometimes necessary to taper the walls of the shell previous to carrying out this operation. The head is then bored and screw-threaded to receive the fuze-hole bush, and the exact ogive given in a "radiusing" machine, which is similar to an ordinary lathe, except that the tool-carrier is designed so as to allow the tool to act on the head of the shell at a variable distance. The base is then faced and turned down to the required thickness.[1] There are also other machining operations necessary, such as recessing the base to permit of the detection of any tendency to weakness at the centre, after which examination a steel disc is inserted in the centre of the base and either screwed in or secured by burring some of the metal of the shell over it by means of a pneumatic hammer. The interior of the shell is sand-blasted, coated with copal varnish, and stoved for six hours. This process gives a very smooth internal surface and it prevents premature explosion from friction, in case of any movement of the explosive arising from bad filling; it also prevents chemical action of the filling on the metal of the shell.

The groove for the driving band is machined, the sides of the groove being slightly undercut to assist in holding the band in place; the bottom of the groove has three or four waved ribs cut along it to prevent the band from rotating in the groove, and two or three chisel-cuts are made across the ribs to permit of the escape of any air while the band is being pressed into position.

The driving bands themselves are made from discs of copper as free from impurities as possible, the best kind being that which has been electrolytically deposited. The discs are formed into cups and are then annealed and drawn alternately until drawn into a long tube, five draws being the usual number. The copper tube is then parted into rings, which are given a final annealing. For banding, the shell are placed in a machine which consists in a circular holder, of which the periphery is divided into segments to which hydraulic presses are attached; a copper band is placed over the shell opposite the groove, and pressure is applied till the band is firmly wedged into the groove. The driving band is then turned to the required shape and dimensions.

Shrapnel shell are manufactured in two designs, those for larger guns having a separate head while for smaller types the head and body are in one. Except that the operation of "bottling" or "heading" can be dispensed with for the larger sizes, the method of making the body is very similar to that for H.E. shell, but from the nature of the design of shrapnel, the body requires some internal machining in addition.

The heads of the larger shrapnel are made of soft steel or malleable iron, prepared to take the fuze-hole bush (the remaining space being filled by a block of wood), and secured to the body by pins and rivets and soldering firmly enough to ensure that the whole shell rotates in flight as a single body.

The cups for the opening charge are made from tin-plate, and the steel diaphragms from discs sheared from a billet of steel, stamped into shape,[2] and then brought to the required dimensions by grinding; a hole is bored in the centre and screw-threaded to receive the central tube, which is made from a butt-ended tube, and is turned and screw-threaded at its lower end to fit the central orifice of the diaphragm. The socket to receive the fuze is a brass stamping, screw-threaded internally to take the fuze and externally to screw into the body of the shell.

Pointed shell may be of three types, which are in Great Britain designated—common pointed, common pointed capped, and armour-piercing. The operations in manufacture are very similar in each case. For A.P. shell, more work is put into the steel in order to make it as strong as possible and for this reason these shell are usually forged. The common-pointed and common-pointed-capped shell are punched and drawn in the usual manner. The shell then undergo a heat treatment in order to remove any strains which may have been set up, the temperature of the furnace being raised to about 1,100° F. After treatment the usual machining operations are carried out, and the shell are then heated up again and hardened by being quenched in an oil bath. Since it is required to retain only the head in a hardened condition,[3] the remaining part of the body is then "let down" by being immersed in a heated bath of lead to a short distance below the shoulder; this process removes the hardening effect and leaves the body tough instead of brittle.

The hardening of the head is liable to cause the occurrence of spontaneous splits; and shell are therefore stored in the open for a period so as to allow time for any splits to develop before filling. Should a split extend to the cavity of the shell when filled, the sudden fracture might cause the explosion of the bursting charge; consequently the shell are fitted with aluminium containers which, as thin cones, are inserted into the shell and spun into position.

The interior of the body is then bored to its final dimensions and the lower end of the cavity screw-threaded to receive the adapter which carries the base fuze. The shell are then banded and the interiors varnished.

Adapters (which vary in size from a mere fuze-hole lining to what is almost a base in itself) are cut from the billet and screw-threaded externally to fit the shell and internally to take the fuze. In some cases a further organization of the adapter base is required to prevent a possible inrush of propellant gas round an ill-fitting fuze into the interior of the shell; this consists of a copper gas-check plate over the fuze, held inside a steel cover which is bound to the adapter base by a locking ring. In such designs the adapter base flange is prepared accordingly during manufacture (fig. 1).

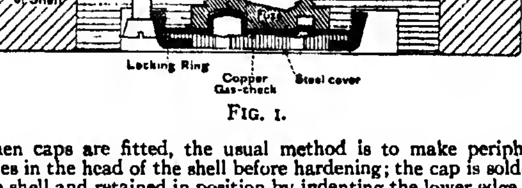

FIG. 1.

When caps are fitted, the usual method is to make peripheral notches in the head of the shell before hardening; the cap is soldered to the shell and retained in position by indenting the lower edge into these notches. Other methods of securing the cap are also in use.

Shell Manufacture in War Emergencies.—In the adaptation of the engineering industry to the manufacture of shell, the capability and capacity of the plant installed in any one workshop is the ruling factor governing the work to be allotted to that shop. The design of the shell must of course be simplified as much as possible to suit the existing machines. The very rapid output requisite and resulting from any such adaptation necessitates that the various stages

[1] As the base is the heaviest part of the shell, it is in this operation that the various shell are brought (as nearly as possible) to uniform weight.

[2] These diaphragms can also be made from drop-forgings.

[3] In the case of common pointed, the head is not hardened.

in the process of manufacture must be semi-automatic at least and, consequently, the organization of the shop and the machines having been adjusted with that object, the labour employed must be arranged for purely repetition work, for which it can be trained easily and quickly.

Having regard to this, and to the capacity of an ordinary engineering shop, it is essential to allocate only a certain number of stages in any one process to any one workshop, suitably arranging the stages to the power of that shop.

The machines mostly to be found in an engineering shop can generally be adapted for any of the operations required in the machining of shell. The ordinary engine lathe can be easily converted for the boring and machining of larger shell, and drilling machines and turret lathes for the same operations with smaller shell. The main point to be considered is the provision of suitable jigs and gauges to enable every operation to be performed by semi-skilled labour in rapid repetition. For hydraulic-press forging of bodies of shell and for the pressing on of driving bands, however, the machines necessary are not usually to be found in the ordinary engineering shop; and as it is not easy to find substitutes on account of the high pressure requisite in working, and the manner in which it is necessary to apply that pressure, arrangements for these operations have to be made specially. But with a certain few specially arranged shops of such nature, a supply of part-wrought material could be easily put out sufficient to keep fully employed a relatively large number of ordinary engineering shops adapted for the machining operations. (F. M. R.)

Cartridges and Primers for Ordnance

Cartridges for ordnance may be divided into two main classes—technically called "breech-loading" and "quick-firing"—and each class subdivided into gun and howitzer cartridges. All guns are nowadays breech-loaders, and the main classes mentioned above are termed B.L. or Q.F. in reference to the system of "obturation" (breech-sealing) employed with the gun. With the B.L. obturation is effected by the breech mechanism, while with the Q.F. it is effected by the cartridge case.

The envelope of cartridges for B.L. guns must be of a material which will stand wear and tear when filled, not deteriorate from chemical action of the explosive while in store, not have injurious effects on the explosive, and be entirely consumed in the gun when the charge is fired, leaving no débris smouldering in the gun after the charge has been fired. Silk cloth made from the refuse silk from the outside of cocoons has been found to be the best material for the purpose.

The propellant explosive, according to the nature of the gun, is either cordite, N.C.T. (nitrocellulose tubular), or ballistite.

All smokeless powders are somewhat difficult to ignite in a gun. Therefore, to make ignition certain and to prevent hang fires an igniter of fine grain gunpowder is used with every cartridge. This powder is enclosed in a bag of shalloon, which is attached to the cartridge in such a position as to intercept the flash from the tube.

Prior to the use of any batch of propellant for cartridges, it is necessary to prove the propellant, as received from manufacture, in order to ascertain whether it conforms to specification requirements. In a chemical test a small amount is subjected to certain analytical tests. In a ballistic test a certain number of charges, made up according to the intended design of cartridge, is fired in a comparative trial against a like number of similar charges of a batch of propellant known as a "current standard." Current standards are compared in a similar manner with a "master standard," the ballistics of which have been ascertained under certain specific conditions. By this comparison, both in the velocities given to the projectile and in the pressures given in the gun, the variation from the standard is found for the batch, and any adjustment in the weight of the charge necessary for the intended cartridge can be determined.

B.L. cordite cartridges are built up of bundles of cordite in the form of sticks cut to the required lengths, and the bundles are tightly tied with silk and inserted into silk cloth bags, of which the ends are closed by discs of similar cloth. An igniter is stitched on to one or both ends of the cartridge. The exterior is laced with silk cloth tape so as to form a stiff cartridge. The charges for heavy guns are made up in separate portions containing half and quarter charges for convenience of handling and to allow of a reduced charge being used. For some of the longer guns the exterior of the cartridge is made cone-shaped, the coned form being produced by building up layers round a cylindrical core. In large cartridges a silk cloth becket runs up the centre and has a loop at the top for handling.

N.C.T. and ballistite have been used only for cartridges for smaller natures of guns. The method of making-up need not be described here; but it may be pointed out that, not being like cordite, in the form of sticks, they do not make up into such compact cartridges, and that ballistite does not need an igniter.

For howitzers, variable charges are required, and cartridges must be built so that charges can be readily altered. Moreover, since a howitzer is shorter than a gun of the same calibre a lighter charge of cordite of smaller size is required, to ensure the charge being usefully consumed before the projectile leaves the barrel. The cartridge is formed of a mushroom-shaped core made up in a bag to which the igniter is attached. On the stalk, so as to be easily removable, are placed the remaining portions of the cartridge made up in the form of rings, attached to the stalk by silk braids or light sewing. The weight of cordite in the rings is so graduated that by detaching one or more, the varying charges required can be obtained.

With Q.F. cartridges the charges are contained in brass cases. This class of ammunition is of two types: (i.) "fixed ammunition"—in which the projectile is fitted into the mouth of the brass case, thus closing it; (ii.) "separate ammunition"—in which the projectile is separate from the cartridge. The brass case itself effects obturation in the gun, for, when the cartridge is fired, the case expands slightly and tightly fits the chamber of the gun, thus preventing any escape of gas through the breech.

The use of the brass case influences rapidity of fire in that it obviates the necessity for sponging out the gun after each round to remove smouldering débris; it allows of the cartridge carrying its own means of ignition, so avoiding the separate operation required with B.L. cartridges. The brass case also offers the advantage of greater safety against the risks of catching fire, and double loading of a gun is an impossibility.

This class of cartridge is especially useful for smaller natures of guns; but with larger natures of guns the rate of fire is nowadays not appreciably affected.

On the other hand the expense of the brass case is a serious consideration; and should a case, by reason of a flaw or split, fail to effect obturation, serious damage may be caused to the gun. Further, in emergencies, failure in the supply of brass might seriously hamper output.[1] The brass case causes a large increase in weight to the cartridge, and so entails increase in means of transport. And as, to save material and expense, fired cases are collected, repaired and used several times over, considerable labour is involved in the salvage and transport.

The use of Q.F. ammunition has been restricted in the British service principally to smaller natures of guns; but the Germans have employed metallic cartridge cases for the largest natures of guns, probably on account of the difficulty in ensuring trustworthy obturation by any other means practicable with sliding-wedge breech mechanisms, and also in the naval service owing to their giving greater safety from premature ignition.

The manufacture of the brass case is a lengthy process and requires care to ensure satisfactory results. The case is made from a disc of suitable thickness, which, being pressed through dies by hydraulic power, is shaped first into a cup and then gradually into a solid-ended cylinder. In order to relieve the stresses set, up the case is annealed between each draw. The head of the case is machined round the solid end to form a rim, by means of which extraction by the breech mechanism of the gun is effected. And, after having been passed through a die to give the taper required to allow of easy loading, the case is subjected to the final operation of machining to specified dimensions and to prepare the central hole in the head for reception of the means of ignition.

Charges for Q.F. cartridges are made up similarly to those for B.L. cartridges. Where necessary distance pieces of papier maché tube and felt wads are used to fill up the space in the case, and so prevent any movement of the charge. The lower end of the charge is splayed out to fit round the hole for the means of ignition, and in cases where this is a cap a small igniter of powder enclosed in a shalloon bag is placed next the flash hole of the cap in order to increase its effect.

With fixed ammunition the mouth of the brass case is closed by the projectile, which is covered on the outside, below the driving band, with a cement to give a water-tight joint, and retained in position either by the lip of the case being pressed over a slightly coned portion prepared on the projectile, or by indentations in the lip of the case being pressed into a groove on the periphery of the projectile. With separate ammunition a cardboard disc and felt pad are inserted above the charge, and then a lid of white metal retained in position by small tongues turned down from the lip of the case.

For cartridges for Q.F. howitzers the charge is made up similarly, but as the charges must be easily adjustable separate ammunition must always be used, and the cartridge arranged so that the lid of the case may be easily removable. The mouth of the case is closed by a removable cup-shaped cardboard disc, and sometimes, as a greater protection against moisture, by an india-rubber cap which fits tightly round the mouth of the case (see fig. 1).

In order to reduce the flash on discharge of a gun *anti-flash charges* have been under experiment. A small charge of ammonium

[1] Towards the end of the World War steel cartridge cases were employed by the Germans as a substitute for brass, but only for rifles and to some extent for light machine-guns. (C. F. A.)

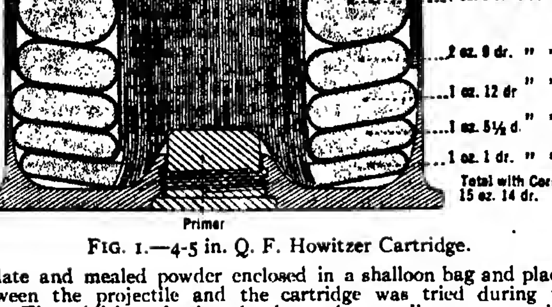

FIG. 1.—4-5 in. Q. F. Howitzer Cartridge.

oxalate and mealed powder enclosed in a shalloon bag and placed between the projectile and the cartridge was tried during the war. The addition of mineral salts such as sodium or potassium chloride has also been tried; but so far the results have not been very satisfactory.

Means of Ignition.—Amongst the various methods that have been evolved for the firing of the gun only the friction tube, the percussion cap, and the electric bridge are now in general use, and of these the friction tube is practically confined to old models of guns continued in the service of various countries owing to the need of all available material in the early and middle stages of the World War.

With the percussion tube[1] ignition of the powder in the body of the tube is obtained from a blow on the head of the "striker," which drives a percussion cap against a hollow brass anvil. The cap consists of a copper shell, cup shaped, coated on the interior with fine varnish; this shell is filled with a chlorate mixture, a thin tinfoil disc is pressed in, and a coating of varnish applied in order to prevent excess of moisture. Internal sealing is obtained by the shell of the cap being expanded into its seating by the force of the explosion.[2]

There are two types of electric tube, one with external wires for joining up with the electric circuit and the other without external wires. In the former two insulated wires are led into the interior, and in each circuit with these there is a wire "bridge" of platinum silver surrounded by a priming composition of gun-cotton dust and mealed powder. On an electric current passing, the bridge is heated to incandescence and ignites the priming composition. In the second type (see fig. 2) the breech mechanism of the gun makes electric contact with an insulated disc in the head of the tube; this disc is connected by an insulated wire to an insulated brass cone, the bridge being formed from the edge of the cone to a brass wire soldered to the mouth of the tube; priming composition surrounds the bridge. The electric current passes from the breech mechanism to the disc in the head of the tube, thence through the bridge to the body of the tube and through the metal of the gun. Internal sealing is obtained by the cones being driven backwards into conical seatings.

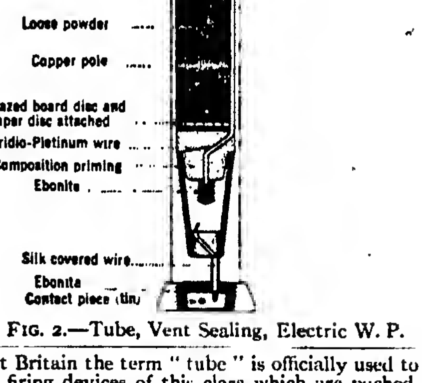

FIG. 2.—Tube, Vent Sealing, Electric W. P.

[1] In Great Britain the term "tube" is officially used to designate the smaller firing devices of this class which are pushed into position, and "primer" for the larger ones which are solidly screwed into the base of Q.F. cartridge cases. In the United States the term "primer" is common to both. (C. F. A.)

[2] In some instances during the war period firing was done by means of a cut-down service rifle screwed into the breach of a gun; in this case an ordinary blank rifle cartridge acted as a percussion tube. (C. F. A.)

With Q.F. cartridges the means of ignition are carried in the base of the brass case, and may be either (*a*) a percussion cap, (*b*) a percussion or an electric primer, (*c*) a percussion or an electric tube held in an adapter. The percussion cap is precisely similar in principle to that of a rifle cartridge and needs no description. The primer is used with larger guns and affords easily replaceable means of ignition. In both percussion and electric types the body of the primer is made of an alloy resembling brass; externally it is screw-threaded to screw into the recess prepared in the base of the cartridge case, internally it is recessed to form a magazine. The percussion primer is fitted with a percussion cap resting on an anvil pierced with flash holes; the anvil is recessed to hold a copper ball and retained by a screwed plug also pierced with flash holes. The action is the same as with a percussion tube; internal sealing is obtained by the copper ball being driven backwards in the coned recess in the anvil. The electric primer is similar to the vent-sealing electric tube in construction and action.

The primer is being superseded by a vent-sealing tube held in an adapter externally of the shape of the primer. The adapter is bored internally to receive the vent-sealing tube, percussion or electric, which is retained in position by a small stud operated by a spring. Attached to the front of the adapter is a metal container filled with a small charge of gunpowder to augment the flash from the tube. (F. M. R.)

FUZES

A fuze is the device or mechanism that ignites the bursting charge of a shell fired from a gun, howitzer or mortar. Fuzes fall into two categories, those which burst or open the projectile in flight (*time fuzes*), and those which burst it on impact or graze (*percussion fuzes*). Of the former all, with the exception of the recently introduced clockwork fuzes, rely for their action on the known speed of burning of a readily ignited composition. In the days of muzzle-loading guns the flash of the powder charge ignited this composition, but in the modern breech-loading guns the passage of the burning gases is checked by the driving band of the projectile, and other means have to be employed for its ignition.

The percussion fuzes in nearly all cases rely for their action on a movable pellet in the interior which—held in position by a shearing wire, centrifugal bolts, the direct pressure of the powder gases (as in some base fuzes) or other means—is released by the shock of discharge and is free to move. The fuze is then described as "armed."[3] The pellet is provided with a disc of detonating composition at the end which is foremost when the shell is in the gun and on graze or impact the pellet flies forward, and the patch of detonating composition impinges on a sharp point or "needle" in the front end of the fuze, the flash igniting a charge of gunpowder or other explosive in the "magazine" and this in turn igniting the bursting or opening charge of the shell.

In the large proportion of time fuzes the same principle, *i.e.* the movable pellet and detonating patch, is relied on for the ignition of the ring or rings of composition. A precaution is necessary, however, with regard to these pellets when free to move in the interior of the fuze, as it has been found that they, not being exposed to air resistance, have a tendency to move forward as the shell loses velocity, and thus to cause premature bursts in flight. To counteract this tendency weak spiral or "creep"-springs are so fitted as to control the forward movement of the pellet. There are other additional devices to secure the proper arming and subsequent action of the fuze which will be described in due course.

All fuzes are screwed into a bush or adapter either in the head of the shell (*nose fuzes*) or, in case of solid-pointed shell, into the base (*base fuzes*). With certain "false-cap" shell the fuze is internal, that is, inside the false caps, but it is in effect a nose fuze in that it is placed in the front of the explosive container.

Percussion Fuzes.—Among percussion fuzes the simplest are those known as direct action, and a British example known as Fuze No. 44 is shown in fig. 1. This fuze is provided with a safety shutter—a device to which reference will frequently be made in the sequel—and for safety in transport is fitted with a cap and with a safety-pin which blocks the moving parts. On loading, the cap and safety-pin

[3] All fuzes before acceptance as service stores are subjected to rough-usage trials to test their powers of resistance to shocks during transport, and it will be understood that the process of "arming" is necessary both to secure this and to prevent premature action in the gun.

attached to it are withdrawn and the head of the fuse exposed. In this is a needle supported by a copper disc over a detonator. Under this a pivoted shutter, kept in position by a spring, closes a channel leading down to the magazine, which is filled with a detonating composition known as "C.E." On firing, the shock of discharge does not

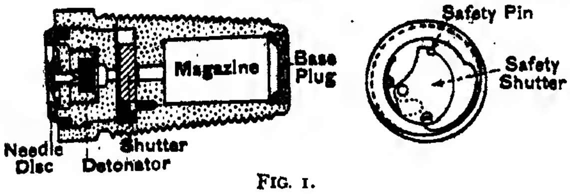

FIG. 1.

affect the relation of the parts but, after a certain small interval of time, the rotation of the shell causes the shutter to swing outwards round its pivot, overcoming its spring and uncovering the fire channel. On impact the needle is crushed down on the detonator, the flash from which, travelling down the now open channel, fires the magazine and explodes the shell.

Fuze No. 134 (fig. 2) exhibits some interesting characteristics. It is a "delay-action" fuze, *i.e.* it is so arranged as to burst its shell about 0·20 of a second after impact. The pellet of this fuze is provided with three inclined projections. The construction of this pellet, of which the upper part is bored out for the reception of the detonator and the lower portion serves as a support for the guard spring, will be best understood from the figure which also shows the position of this pellet before firing and when "armed" after firing.

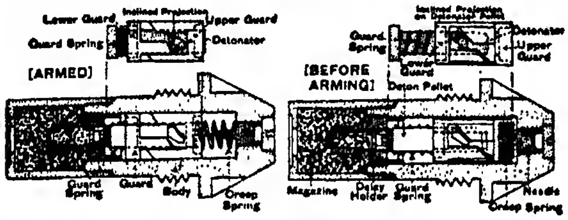

FIG. 2.

The action is as follows: Before firing, "ramps" or inclined surfaces formed on the upper guard bear against the upper portions of the inclined projections on the detonator pellet, and are held there by the creep-spring, while the base of the lower guard is pressed upwards against the bottom of these projections by the guard-spring. The two guards and the projections being thus locked by the friction of their surfaces, the guards completely mask the detonator. On the shock of discharge the lower guard sets back, compressing the guard-spring. The "ramps" on it ride down the inclined projections on the pellet, giving the guard a slight movement of rotation. The upper guard, impelled by the creep-spring, is then free to follow the lower, and the detonator is unmasked. The guard-spring then reasserts itself, and its upward pressure jams the guards in the set-back position. On impact the pellet moves forward, overcoming the creep-spring and carrying the detonator on to the needle. The flash from the detonator ignites some mealed powder in the interior of the pellet which communicates with the delay composition, this in turn, after the momentary delay desired, igniting the magazine.

Fuze No. 18 is a simple fuze, the action of which will be understood from fig. 3. It is protected by a strong cap which is removed at the

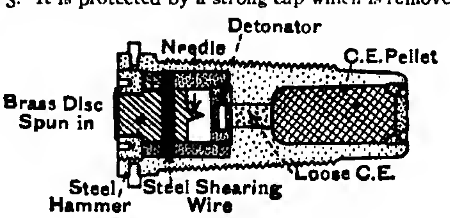

FIG. 3.

last moment before loading. The fuze is quiescent in all its parts until direct impact takes place, when the steel hammer is crushed in and, breaking the steel shearing wire, carries its needle-point on to the detonator. The explosion of the detonator fires the loose exploding composition (loose C.E.) in the central channel, which in turn fires the magazine of the fuze (C.E. pellet) and the bursting charge of the shell.

A variation of No. 18, known as No. 45, has a pivoted safety shutter which is similar to that of No. 44, except that when it rotates, instead of merely opening communication between the detonator and the magazine, it brings a patch of composition of its own under the detonator to reinforce the downward flash.

In Fuze, Percussion, No. 106, which is of the instantaneous class, the principal feature is that it is armed by the unwrapping of a steel tape with a weighted end. The general construction will be understood from fig. 4 which shows the fuse uncapped and ready for firing. A split steel collar is interposed between the under side of the ham-

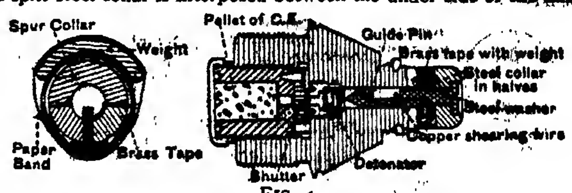

FIG. 4.

mer-head and the top face of the fuze body, and it is round this collar that the tape is wound. On firing, the weight at the end of the tape is gripped by the set-back of the hammer, which receives additional support from the steel split collar. When acceleration ceases—that is, when the shell leaves the bore—the weight is released, flies off, unwinding, and carrying the tape with it. The segments of the split collar are torn away by the end of the tape, and the hammer is then supported only by a thin shearing wire. On impact (even the slightest) the hammer is driven in, shearing the copper wire and the detonator is fired. The fuze shown in the figure is a variant, No. 106 E, in which, owing to the inherent sensitiveness of fuzes of this class, a safety shutter is introduced. This shutter, like that of No. 45 alluded to above, carries a composition relay.

No. 106 and its variants were the standard instantaneous fuzes of the British artillery in the World War. Introduced in 1916, some 88,000,000 were made, and at the end of the war they were being turned out at the rate of a million a week, about one-third of those being made of cast iron.

No. 146, also armed by an unwinding tape device, is known as the "All-ways" fuze. It is designed to act and burst its shell at whatever angle the latter may strike the ground. It is used only for trench-mortar bombs. For rifled shell, which travel nose first, such a fuze is not necessary, but for many trench-mortar bombs, which may fall sideways or on their bases, a percussion fuze is impracticable unless it possesses this characteristic. Fig. 5 shows the final form of the British "All-ways" fuze developed in the war from a crude German archetype. It is called No. 146 MK. V., or the Spigot fuze, as it is screwed on to a spigot which projects from the bomb.

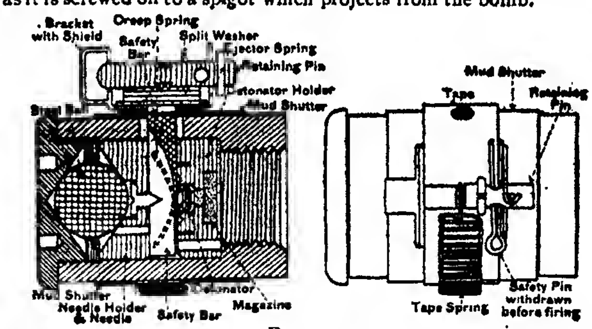

FIG. 5.

On firing, the shock of discharge dislodges the retaining pin and the tape spring causes the tape to unwind, thus permitting the ejector spring to eject the safety bar from the body of the fuze. The "mud shutter" then drops and closes the hole in the body, thus preventing the interior of the body from being filled with mud on falling to the ground. Only a light strip of spring steel now keeps the detonator and the needle apart. On impact one of two things takes place, whatever the angle of fall. Either the steel ball forces the needle holder down on the detonator, or the latter moves forward carrying its detonator on to the needle.

Graze Fuzes rely for their action on the check to the forward movement of the shell that takes place on graze or impact, and not essentially on a blow delivered to any part of the fuze. They are therefore very sensitive and depend for their action on a pellet inside the fuze which moves forward on graze, causing a needle to come in contact with a detonator. Special arrangements are provided to guard against premature action in transport, handling and loading, on discharge, while the shell is in the bore, and during flight before it strikes or grazes. With these fuzes there is always a slight delay in action, and in some cases an additional delay-action is provided which is sufficient to cause the burst to occur well below the ground surface, or, if the shell ricochets, 10 to 50 yd. in front of the graze. In view of the danger to equipment and to personnel in the event of such a shell exploding prematurely there is incorporated with the fuze either a shutter or a "delay," either of which modifications (to be described subsequently) should ensure the burst of the shell not taking place until it is some distance clear of the gun.

An example of this class is the British Fuze No. 101 E. It will be seen in fig. 6 that the detonator is contained in the graze pellet. With this arrangement it is possible for the needle to fire the detonator when the cap is crushed in on impact (although the graze pellet may not have acted).

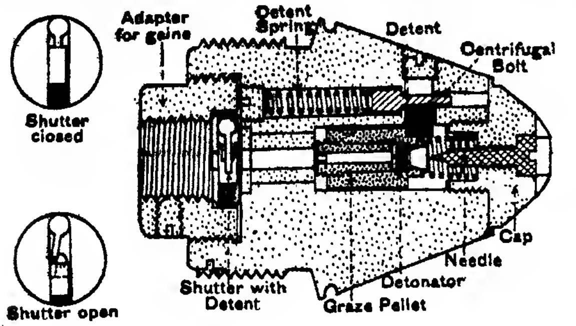

Fig. 6.

The shock of discharge causes the detent to set back, compressing its spring. Then the detent spring, reasserting itself, jams the point of the detent under the projecting shoulder, so that it cannot return to its original position blocking the centrifugal bolt. This bolt, actuated by the rotation of the shell, moves outwards, freeing the graze pellet. The latter is restrained from working forward during flight by a creep-spring. On graze or impact the pellet, overcoming the creep-spring, flies forward, and the detonator is fired by coming in contact with the needle. The flash passes into the "gaine" and this detonates the shell.

In the earliest models of the same class the detent alone was relied upon to give safety, but in the fuze illustrated and also in others, as an additional precaution, a shutter is introduced to mask the flash-hole until the shell is clear of the gun. This consists of a block held in the closed position, with its centre of gravity eccentric to the axis of the fuze, by a compressed spring and a detent with a weighted head. While the shell is going forward in the gun, the shutter is held in position by the spring, but on leaving the gun the rotation of the shell overcomes the spring, and the shutter moves outwards, uncovering the flash-hole; at the same time the tail of the detent is released from its recess in the shutter, moves to one side, and prevents the shutter from returning and masking the flash-hole.

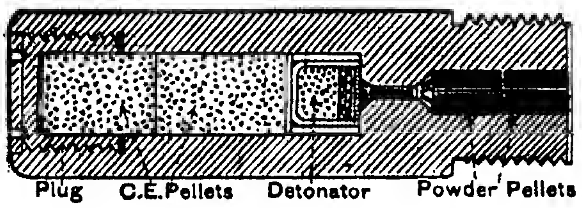

Fig. 7.

High explosives used as bursting charges, being comparatively inert and safe substances, require a violent detonation actually in contact with them to ensure that they shall detonate and not merely explode. This result is obtained by interposing a certain amount of less inert explosive between the bursting charge and the magazine of the fuze. In some cases this relay or part of it is placed in a steel or bronze container called a "gaine," which is screwed to and forms an integral part of the fuze.

Fuzes of the class described here are always used with a gaine (which is screwed into an adapter and so secured to the base of the fuze), the flash being inadequate in itself to secure detonation of the contents of the shell without being assisted by a relay. The internal arrangement of a gaine for use with these fuzes will be seen in fig. 7. The flash from the fuze ignites the perforated pellet. The flame from this passes through a flash-hole to the detonator, which, when fired, detonates in its turn two pellets of exploding composition (C.E.) or of picric acid, and these finally detonate an "exploder" bag placed choke downwards below the gaine in the cavity of the bursting charge. This train of three detonations detonates the H.E. in the shell. When a delay composition is included it is placed at the mouth of the gaine, above the powder pellets.

Base Fuzes.—These are for use in shells having solid-pointed heads. That in general use for common-pointed and armour-piercing shells comes under the category of graze fuzes and is known as Fuze Percussion, Base large, No. 11.

The pellet is locked by a device which primarily releases it when acted on by the pressure of the propellant gases, its final release being accomplished by the rotation of the projectile. Safety shutters prevent the magazine from being fired should the detonator act prematurely.

The pellet is locked in its rearward position by a bolt projecting into a recess in its body, and is held in this position by the stem of the pressure-plate. This plate is fitted into a socket, and is made accident-proof by a steel protecting plate, perforated so that the gas pressures may act on the pressure plate.

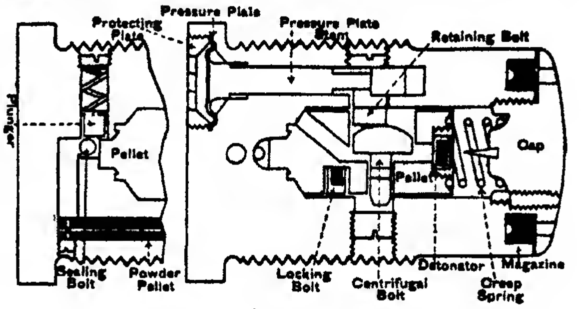

Fig. 8.

When the pressure plate is driven in on firing, a recess in the stem is brought opposite to the fork of the retaining bolt, so that this is now free to move outwards. The mushroom-headed centrifugal bolt moves outwards on rotation being set up, and forces the end of the retaining bolt into the recess exposed by the movement of the pressure-plate stem. At the same time the tail of the centrifugal bolt—which hitherto, by engaging in a recess in the body of the fuze, has prevented the rebound of the pellet on shock of discharge—is withdrawn and the pellet is now free, its movement being only controlled by the creep-spring.

On impact the pellet moves forward and the needle penetrates the detonator. The flash from this passes through a passage in the pellet and centrifugal bolt, along a transverse channel, and ignites a vertical column of compressed powder leading to the magazine. This is a ring of compressed powder in a recess in the upper part of the fuze body, the powder being grooved on the under side so that the flash may pass all round and ignite the whole ring simultaneously. The flame from the magazine passes through holes in the cap to the bursting charge of the shell.

Premature action on this fuze is guarded against in three ways: First, the spindle of the centrifugal bolt masks the passage through the pellet until the shell has gained a suitable speed of rotation; secondly, the coned seating at the base prevents the escape of flash coming over or through the pellet; and thirdly, a ball in a seating at the end of the transverse channel is held in position by a spring-controlled plunger that moves outwards, the ball following it when sufficient rotary movement has been set up.

To prevent a "blind" being caused on impact by the rebound of the pellet there is a spring-controlled locking bolt in the side of the pellet so arranged as to enter a recess in the body of the fuze when the pellet has gone forward a certain distance; this permits of further forward but no backward movement or rebound due to the creep-spring.

One of the earliest and simplest of the base fuzes is the Base Hotchkiss Fuze (fig. 9) used mainly for small Q.F. guns.

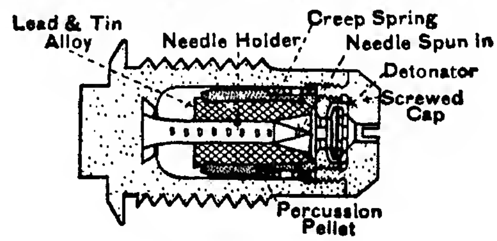

Fig. 9.

On the shock of discharge, the pellet sets back over the needle holder, thus allowing the steel needle to project beyond it. The alloy at the bottom of the pellet cushions against the bottom of the fuze, and a small portion of it dovetails into the undercut recess, round the base of the needle-holder. This forms a weak connexion between the pellet and fuze body, and assists the spring in checking rebound action. On graze or impact, the pellet and needle set forward, the needle pierces the detonator, and the flash passes through to the bursting charge of the shell.

Time and Percussion Fuzes, as their names imply, are intended to burst their shells either in the air in front of the target or on impact. Setting aside for the moment the newly developed clockwork fuzes, the T. and P. Fuzes used in Great Britain depend for time of burning on rings of compressed composition which are ignited at the moment of discharge, and of which the flame is conducted by suitable passages to the magazine. The opening charge of the shrapnel is thus fired at a moment predetermined by the setting given to the time rings above

mentioned, one of which is movable, the other fixed to the body. The rings are pressed together by the cap of the fuze, which is screwed down tightly enough to prevent the movable ring from being shifted otherwise than by a spanner called a "fuze key," so as to ensure regular adjustment of the ring and to prevent it from slipping after being set. Many factors govern the rate of burning of the time rings. Primarily there is the pressure prevailing at the burning surface; this again depends on the pressure produced by the burning composition at the escape outlets, and this again depends largely on the speed of revolution and of translation, the position of the outlets with regard to the body of the fuze, the shape of the fuze, the height to which the shell is fired, the barometric pressure, and the nature of the gun from which the shell is fired.

Time and percussion fuzes are used normally with shrapnel, but rarely with H.E. shell.

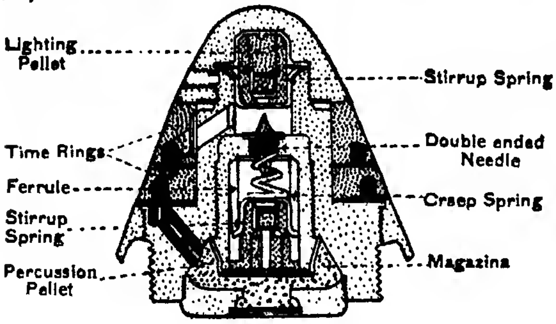

Fig. 10.

In the Time and Percussion Fuze No. 80 the upper time ring is fixed to the body by pegs, but the lower ring can be rotated for setting (fig. 10). Immediately below the cap is the mechanism for igniting the composition. This consists of a lighting pellet fitted with a detonator and supported by a stirrup spring which keeps it away from the needle below it.

On shock of discharge the pellet sets back, straightening out the arms of the stirrup spring, and the detonator comes in contact with, and is fired by, the needle. The flash from the detonator passes through a slanting channel and ignites the composition in the upper ring. The flame then travels in the direction in which the shell is rotating until, after an interval of time determined by the setting, it reaches a passage communicating with the lower time ring. Here there is a compressed powder pellet to ensure more certain ignition. The composition in this second ring, being thus ignited, burns in the reverse direction until, at the time determined by the setting, it reaches the compressed powder pellets in a passage leading to the magazine, the flash from which, passing down a tube in the shell, fires the opening charge.

The percussion pellet is held away from the lower point of the needle by a ferrule supported by a stirrup spring, a creep-spring preventing any forward movement during flight. On graze or impact the percussion pellet flies forward, and the detonator, impinging on the point of the needle, fires, and its flash passing through the pellet fires the magazine.

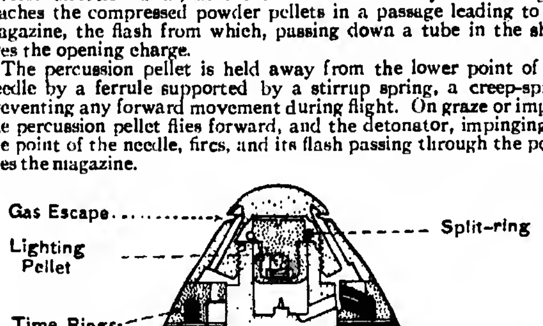

Fig. 11.

In general arrangement Time and Percussion Fuze No. 85[1] greatly resembles No. 80. There are, however, some important differences (fig. 11).

The lighting pellet is supported by a ring sprung into a groove in the pellet and resting on the rim of a recess in the stem of the body. On the shock of discharge the pellet escapes from the ring and sets back on to the needle which fires it, the flash igniting the time ring as in Fuze 80. Another interesting characteristic of this fuze is that the gases, instead of escaping directly through holes in the rings, pass into a series of channels before finally escaping through a circumferential groove in the cap. With this modification the rate of burning of the time ring is less affected by variations in barometric pressure and the other disturbing factors above mentioned. The main difference between these two fuzes is, however, in the percussion arrangement. This consists of a pivoted needle pellet or block and a detonator supported in the upper part of the recess. The block, which is pivoted, is kept in position by centrifugal bolts. These in due course free the block, which swings round on its pivot, bringing the needle opposite the detonator. Spring plungers prevent the pellet from creeping forward in flight. On graze or impact it flies forward, overcoming the spring plungers, and fires the detonator. The flash from this passes down a passage in the body (dotted lines) and fires the magazine.

In T. and P. No. 83, a variant designed specially for medium guns and howitzer, a special safety device is provided in the shape of a ball, which is trapped between the ferrule and the detonator pellet and the striker until the ferrule sets back, when the ball acts as a temporary safety between pellet and striker. When sufficient rotation has been set up, the ball flies up into a side channel, and the pellet is now only held back by a creep-spring which on impact is overcome.

Time fuzes without percussion elements are now of no special interest except in connexion with anti-aircraft fire. It is essential to render all shell fired at aircraft that might fail to burst in the air as harmless as possible on impact with the ground, owing to the danger to friendly troops and the populations of towns and villages, and buildings. Another use of time fuzes without percussion mechanism is with trench-mortar shell, which do not pitch nose first. In these and a few other special cases the ordinary stirrup spring is too stiff to arm, and a weaker spring is fitted with, as its corollary, a safety-pin for security in transport. All such time fuzes are simply T. and P. Fuzes of the various service patterns converted by the removal of the P. mechanism.

In general the time fuzes designed before and used during the World War were constructed to run for 22 seconds' time of flight. In fuzes for certain longer-ranging ordnance, however (*e.g.* No. 83), 30 and 45 seconds' run was allowed for, and the latest representative of this class, No. 89, which has three time rings instead of two, runs for 60 seconds. Amongst all these No. 80 was by far the most generally used, about 70,000,000 of this type having been manufactured during the war, as well as 18,000,000 of the American No. 85 and 8,000,000 of Nos. 83, 88 and 89. As an instance of how the industry of the country adapted itself to war needs, it is worth mention that the average pre-war output of No. 80 was 55,000 a year, and the output of one firm alone in 1918 250,000 a week.

Last, and for the future most important in the time-fuze category, comes the mechanical or clockwork fuze. This almost eliminates the variations of burst due to atmospheric conditions and to the quality and freshness of the composition used. It had long been sought for by inventors, but until 1916 no type had been produced which gave satisfactory results in practice owing to the great difficulties in designing a mechanism that would run under the conditions of shock and of rotation that a fuze must cope with.

In 1916, however, the Germans brought into use a clockwork fuze, ("Dopp. Z. 16") which proved very successful and has been copied, with little variation, by the British authorities, its British designation being Fuze, Time, No. 200. The German fuze has a percussion arrangement in addition to the clockwork; this is omitted in the British model, which is a time fuze only.

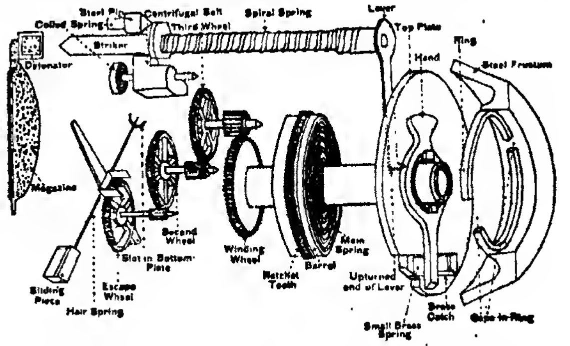

Fig. 12.

The description which follows must be understood as a description of principle and arrangement only, a technical demonstration being impossible without the actual fuze. It must be premised further that the clockwork element is very small in size, being in diameter about equal to an ordinary wrist watch and in thickness to two such watches.

Fuze, Time, Mechanical, No. 200.—The clock train is driven, as in a watch, by a coiled spring in a barrel, but the escapement is original and peculiar. A straight steel spring takes the place of the hair-spring,

[1] This fuze, worked out by J. D. Cushing, was the American army fuze before the World War, and was used in large quantities for British field guns to supplement the available stocks of British fuzes.

which would be rendered useless by the effect of rotation and shock of discharge, and as the length of the straight spring is adjustable, the movement of the pellets of the balance, and therefore that of the escapement wheel and the clock train, are controlled and regulated. A horizontal hand, the position of which depends on the setting of the fuze, has on its under surface a notch into which fits the upturned end of the lever at the top of the striker. When the clock train is started the hand moves round with it, but is prevented from rising and releasing the lever by a ring attached to the conical housing of the fuze. This ring is provided with two slots into which the hand can fit; thus when the clock is working the rotation brings the hand into coincidence with the slots, and when forced up by the action of a small spring, it releases the upturned end of the lever. The striker previous to firing has been held in the safe position by a collar on it which rests on a shoulder of the centrifugal bolt, but when this bolt is moved away by the rotation of the shell, the outer part of this shoulder still rests on a steel pin. When the upturned end of the lever is freed from the notch in the lower side of the hand, as previously described, it flies out and rotates the striker so that the collar clears the steel pin and allows the striker to fall and fire the detonator.

The setting of the fuze and the hand is accomplished by turning the housing with a suitable key, this housing being free to move before firing. On discharge it is very ingeniously clamped to the body of the fuze by means of steel pins in a ring in its under surface. This ring sets back and the pins are driven through the flange of the clock case, a groove being turned on its under side to thin the metal, and thus to allow of easy penetration.

The clock train, wound up like a watch, is started at the moment of firing by the settling-back of a detent.

The British fuzes described above illustrate sufficiently the general principles on which fuzes are designed to serve the various requirements and to meet the various dangers. There are, however, many interesting devices and expedients included in the design of French, German and other fuzes which are not usually employed in Great Britain, and the fuzes described below have been selected as examples of these devices and expedients. Some of these have been copied by British designers.

German Fuzes in general have some marked peculiarities. In the first place, especially in pre-war designs, there is a tendency to excessive complication, due to the desire to make one fuze answer for several functions. Ignoring the case of fuzes for universal shell, in which the complication resides rather in the shell itself than in the fuze, we find fuzes designed for time, impact and delay, or impact, delay and long delay, each system having its own equipment of safety devices as well as suitable setting arrangements. In some cases the channels bored into the fuze body with their cross-connecting channels and sealing devices are so numerous that the interior resembles a veritable rabbit warren. One example only of these complicated fuzes will be described here.

On the other hand, some of the devices employed are elegant in their simplicity, notably the interlocking shutter-leaves described in two of the examples below. Other points of special interest found in German fuzes are—in time fuzes the provision of devices to lock the movable time ring by set-back; and in percussion fuzes (and the percussion element of T. and P. Fuzes) the use of pressed powder pellets or columns as a safety device to seal the working parts until the shell is clear of the gun.

The Instantaneous Fuzes, known in Germany as "sensitive" (*empfindlich*), are quite unlike the British No. 106. Although it appears that the unwrapping device of No. 106 and spigot fuzes originated in a German trench-mortar fuze, it does not appear in any of the instantaneous fuzes used with German guns and howitzers proper, all of which are characterized by a projecting striker rod. This striker rod (very long in the case of shell fitted with false cap) is only inserted at the last moment in the socket prepared for it in the fuze. These sensitive fuzes are all relatively simple and only instantaneous effect is attempted.

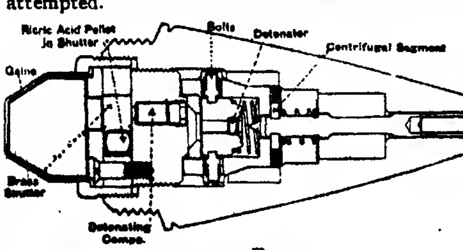

FIG. 13.

The Instantaneous Howitzer Fuze 16 C. (E.H.Z. 16 C., fig. 13) is fitted with a projecting striker rod so that the fuze comes in contact with the ground, etc., a moment before the shoulders of the shell do so, thus detonating the shell before it has time to bury itself. The removable rod fits into a rod which is supported by a creep-spring at its lower end and held in position up to the moment of firing by two centrifugal spring bolts. Below the point of the needle is a small detonator in a holder also kept in position by two centrifugal spring bolts. Below this again is the main detonator, to which the flash from the smaller one is communicated through a suitable channel. This main detonator communicates with the gaine by a fire-hole, but is screened from it by a centrifugal brass shutter, in which—out of line with the detonator-gaine fire-hole—is a charge of explosive.

On rotation being imparted to the projectile the striker needle is freed, as is also the detonator holder below it, and these are then only held apart by the creep-spring. The brass shutter swings outwards, bringing the explosive patch to its position under the main detonator. The fuze is now in all respects sensitive. On graze, the detonator holder flies forward and strikes the needle, which is solidly supported by a plate on the rod kept (by a spring) bearing against shoulders cut in the body. Alternatively, on impact, the striker rod is pushed in, driving the needle on to the detonator holder. In either case the detonator is fired and the flash, relayed by the patch in the shutter, passes to the gaine.

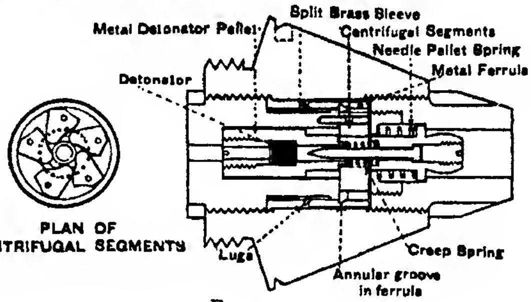

FIG. 14.

In the instantaneous fuze "Granatzünder 17" (Gr. Z. 17), shown in fig. 14, the body is fitted in its lower portion with a bush carrying five centrifugal segments, a split brass sleeve and ferrule, and a detonator holder, to the top of which a creep-spring is soldered. The upper half of the fuze contains a needle pellet and spring, the upper part of which is shaped to take the striker rod, and has projections that, by a spring, are kept bearing on shoulders formed in the body, as in E.H.Z. 16 C. On the shock of discharge the ferrule sets back, overcoming the support of the brass sleeve, and is locked in its rearward position by lugs on the sleeve which engage in an annular groove in the inner surface of the ferrule. The centrifugal segments are now free to take up rotation about their pivot pins, but as they are interlocked, owing to their shape and position, they can only move one at a time, and thus an appreciable interval elapses before the percussion pellet is free. The extremities of the centrifugal segments (aided by the needle-pellet spring) take up the set-back of the needle pellet on shock of discharge, and the creep-spring keeps the percussion pellet away from the needle during flight. On impact the striker rod is driven in and impels the needle pellet, which, overcoming the resistance of its supporting spring, fires the detonator. Should the striker rod meet with insufficient resistance to drive it in on impact, the percussion detonator will still fly forward on graze and fire its detonator as it impinges on the needle, the flash passing into the shell through the passage behind it.

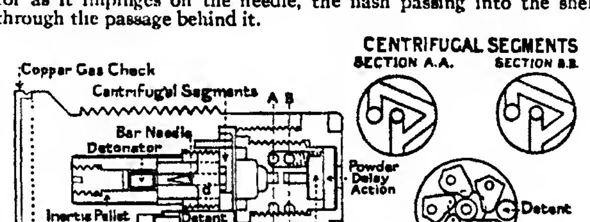

FIG. 15.

This shutter device is also found in an interesting German base fuze (fig. 15), in combination with a detent of the same class as that of the British 101 Fuze, but reversed.

The fuze depends for its action on the inertia of a pellet which remains steady till impact, and then sets forward on to the needle. In travelling, the movable pellet is confined between the shutter and the bottom of its cavity, and set-back on discharge does not affect it. But as soon as the shutter-leaves rotate out of the way it is perfectly free, not even a creep-spring apparently being fitted. On firing the detent flattens its stirrup spring, and sets back, and thereupon, under

mentioned, one of which is movable, the other fixed to the body. The rings are pressed together by the cap of the fuze, which is screwed down tightly enough to prevent the movable ring from being shifted otherwise than by a spanner called a "fuze key," so as to ensure regular adjustment of the ring and to prevent it from slipping after being set. Many factors govern the rate of burning of the time rings. Primarily there is the pressure prevailing at the burning surface; this again depends on the pressure produced by the burning composition at the escape outlets, and this again depends largely on the speed of revolution and of translation, the position of the outlets with regard to the body of the fuze, the shape of the fuze, the height to which the shell is fired, the barometric pressure, and the nature of the gun from which the shell is fired.

Time and percussion fuzes are used normally with shrapnel, but rarely with H.E. shell.

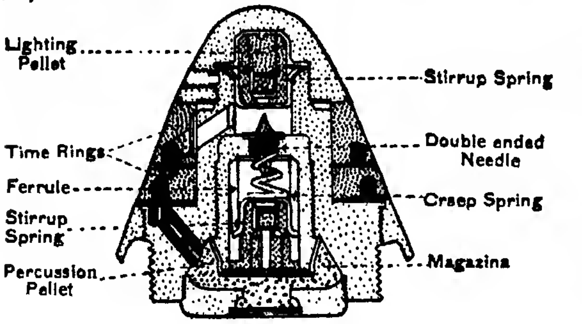

FIG. 10.

In the Time and Percussion Fuze No. 80 the upper time ring is fixed to the body by pegs, but the lower ring can be rotated for setting (fig. 10). Immediately below the cap is the mechanism for igniting the composition. This consists of a lighting pellet fitted with a detonator and supported by a stirrup spring which keeps it away from the needle below it.

On shock of discharge the pellet sets back, straightening out the arms of the stirrup spring, and the detonator comes in contact with, and is fired by, the needle. The flash from the detonator passes through a slanting channel and ignites the composition in the upper ring. The flame then travels in the direction in which the shell is rotating until, after an interval of time determined by the setting, it reaches a passage communicating with the lower time ring. Here there is a compressed powder pellet to ensure more certain ignition. The composition in this second ring, being thus ignited, burns in the reverse direction until, at the time determined by the setting, it reaches the compressed powder pellets in a passage leading to the magazine, the flash from which, passing down a tube in the shell, fires the opening charge.

The percussion pellet is held away from the lower point of the needle by a ferrule supported by a stirrup spring, a creep-spring preventing any forward movement during flight. On graze or impact the percussion pellet flies forward, and the detonator, impinging on the point of the needle, fires, and its flash passing through the pellet fires the magazine.

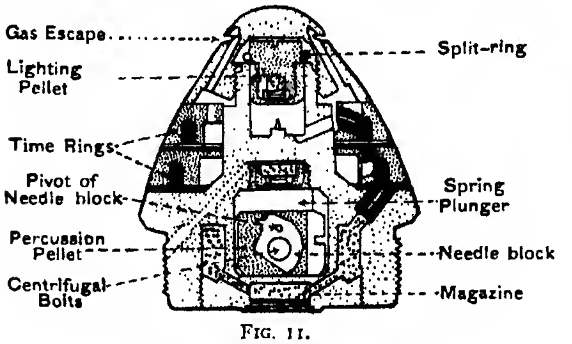

FIG. 11.

In general arrangement Time and Percussion Fuze No. 85[1] greatly resembles No. 80. There are, however, some important differences (fig. 11).

The lighting pellet is supported by a ring sprung into a groove in the pellet and resting on the rim of a recess in the stem of the body. On the shock of discharge the pellet escapes from the ring and sets back on to the needle which fires it, the flash igniting the time ring as in Fuze 80. Another interesting characteristic of this fuze is that the gases, instead of escaping directly through holes in the rings, pass into a series of channels before finally escaping through a circumferential groove in the cap. With this modification the rate of burning of the time ring is less affected by variations in barometric pressure and the other disturbing factors above mentioned. The main difference between these two fuzes is, however, in the percussion arrangement. This consists of a pivoted needle pellet or block and a detonator supported in the upper part of the recess. The block, which is pivoted, is kept in position by centrifugal bolts. These in due course free the block, which swings round on its pivot, bringing the needle opposite the detonator. Spring plungers prevent the pellet from creeping forward in flight. On graze or impact it flies forward, overcoming the spring plungers, and fires the detonator. The flash from this passes down a passage in the body (dotted lines) and fires the magazine.

In T. and P. No. 83, a variant designed specially for medium guns and howitzer, a special safety device is provided in the shape of a ball, which is trapped between the ferrule and the detonator pellet and the striker until the ferrule sets back, when the ball acts as a temporary safety between pellet and striker. When sufficient rotation has been set up, the ball flies up into a side channel, and the pellet is now only held back by a creep-spring which on impact is overcome.

Time fuzes without percussion elements are now of no special interest except in connexion with anti-aircraft fire. It is essential to render all shell fired at aircraft that might fail to burst in the air as harmless as possible on impact with the ground, owing to the danger to friendly troops and the populations of towns and villages, and buildings. Another use of time fuzes without percussion mechanism is with trench-mortar shell, which do not pitch nose first. In these and a few other special cases the ordinary stirrup spring is too stiff to arm, and a weaker spring is fitted with, as its corollary, a safety-pin for security in transport. All such time fuzes are simply T. and P. Fuzes of the various service patterns converted by the removal of the P. mechanism.

In general the time fuzes designed before and used during the World War were constructed to run for 22 seconds' time of flight. In fuzes for certain longer-ranging ordnance, however (e.g. No. 83), 30 and 45 seconds' run was allowed for, and the latest representative of this class, No. 89, which has three time rings instead of two, runs for 60 seconds. Amongst all these No. 80 was by far the most generally used, about 70,000,000 of this type having been manufactured during the war, as well as 18,000,000 of the American No. 85 and 8,000,000 of Nos. 83, 88 and 89. As an instance of how the industry of the country adapted itself to war needs, it is worth mention that the average pre-war output of No. 80 was 55,000 a year, and the output of one firm alone in 1918 250,000 a week.

Last, and for the future most important in the time-fuze category, comes the mechanical or clockwork fuze. This almost eliminates the variations of burst due to atmospheric conditions and to the quality and freshness of the composition used. It had long been sought for by inventors, but until 1916 no type had been produced which gave satisfactory results in practice owing to the great difficulties in designing a mechanism that would run under the conditions of shock and of rotation that a fuze must cope with.

In 1916, however, the Germans brought into use a clockwork fuze, ("Dopp. Z. 16") which proved very successful and has been copied, with little variation, by the British authorities, its British designation being Fuze, Time, No. 200. The German fuze has a percussion arrangement in addition to the clockwork; this is omitted in the British model, which is a time fuze only.

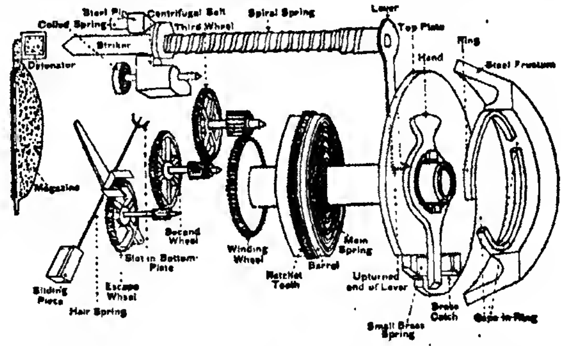

FIG. 12.

The description which follows must be understood as a description of principle and arrangement only, a technical demonstration being impossible without the actual fuze. It must be premised further that the clockwork element is very small in size, being in diameter about equal to an ordinary wrist watch and in thickness to two such watches.

Fuze, Time, Mechanical, No. 200.—The clock train is driven, as in a watch, by a coiled spring in a barrel, but the escapement is original and peculiar. A straight steel spring takes the place of the hair-spring,

[1] This fuze, worked out by J. D. Cushing, was the American army fuze before the World War, and was used in large quantities for British field guns to supplement the available stocks of British fuzes.

parted, whereupon the spring drove the needle on to the detonator and exploded the fuze. (D. D. T. O'C.)

French Fuses, in marked contrast to German, are deliberately simple in type and the number of types also is limited. The four patterns described below may be taken therefore as fully representative of French practice.

The typical pre-war percussion fuze is the direct-action fuze shown in fig. 18. The action will be readily understood from the figure. Before firing, a heavy ferrule is supported between a compressed spiral spring and a stirrup spring which surrounds the detonator pellet. On shock of discharge (aided by the decompression of the spiral spring) the ferrule sets back, straightening the stirrup spring, and fits over both stirrup spring and detonator pellet, being held there by the spiral spring acting as a creep-spring. On impact the pellet and ferrule fly forward together on to the needle, and the detonator is fired. The spiral spring can be adjusted for tension by screwing the closing plug in or out.

A more highly developed design of the same class is Fuze 24/31 P.R. model 1916, distinguished by an ingenious combination of safety pellet and detonator holder which has been copied in the British Fuze No. 134 (fig. 2).

As in other French fuzes, and in British, impact or delay effect is arranged by the design of explosive filling below the main detonator and not by that of elements in the fuze itself.

French instantaneous fuzes are characterized by simplicity and great projection from the nose of the shell, the latter being intended to ensure that the fuze shall act before the shoulders of the shell strike the ground and begin to bury themselves.

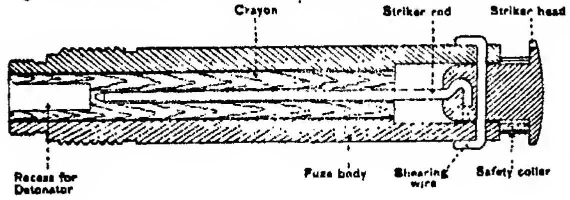

FIG. 19.

A simple representative is shown in fig. 19, which is a cheap and effective trench-mortar fuze. (French trench-mortar projectiles are vaned and so fall nose first.) The striker consists of a head, which in transport is kept off the head of the fuze by a safety ring, and a long striker which is kept centred by a wooden "crayon" in much the same way as the lead is held in an ordinary lead-pencil. Through the head of the striker passes a shearing wire of copper alloy (Cu 67 %, Zn 33 %). Before firing, the safety ring is removed and only the shearing wire keeps the striker point off the detonator. This resists the shock of discharge (which is relatively slight in a trench mortar) but is sheared on impact. It will be observed that the fuze is not sensitive during flight, as the German fuzes and the British No. 106 are, but relies for its instantaneous effect chiefly on the fact that the striker head takes the ground a moment before the shoulders of the shell do so. A fuze of this class when used with a rifled gun would have a centrifugal unwrapping tape similar to that of the British 106 Fuze in lieu of the safety ring. The actual detonator arrangements, not shown, may be varied in the usual way by introducing or omitting a delay pellet. The lower end of the fuze is screwed to receive a steel gaine.

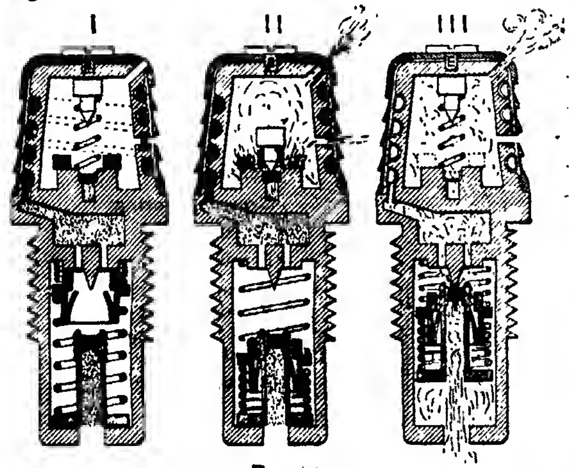

FIG. 20.

The French T. and P. Fuze (*Fusée à double effet 23/31*, fig. 20), designed in 1897, remained in service throughout the war of 1914–8 as the standard time-shrapnel fuze for the 75-mm. field gun. Unlike the British, German, and other T. and P. Fuzes, it is set, not by means of a movable powder ring, but by punching a hole at the appropriate point in a composition-filled lead tube by means of a fuze-setting machine called a *débouchoir*.

The time composition is contained in a sealed lead tube fitting into a spiral groove on the upper and slightly tapered portion of the body. Over the body is a cover on which a long spiral scale is engraved, with graduations corresponding to the appropriate points in the composition worm which lies exactly under it. Certain points on the scale are marked with a hole instead of a figure; these subsequently act as a relief for the gases and slag. To set the fuze a hole is punched by the débouchoir through the cover, lead tube, and body, thus making free communication with the interior. The time ignition pellet (which carries the needle in this case) is kept away from the fixed detonator by a coiled spring which it overcomes on shock of discharge. The resulting flash from the detonator ignites a powder pellet, which gives a powerful flame filling the interior of this part of the fuze, and lighting the composition in the lead tube as it passes through the hole punched by the fuze-setter. The composition then burns along the tube until the flame reaches the end of the lead tube, whence it passes by a cross channel to the magazine. (A peculiarity of the French fuze is that the flash from the magazine, instead of passing by a channel of its own to the interior of the shell, ignites the detonator pellet of the percussion system, which thus acts as a relay.)

The percussion system consists essentially of: (*a*) a ferrule provided externally with a collar and internally with a spring catch device; (*b*) a detonator holder, hollow to take the detonator and a magazine of fine-grain powder underneath it, and provided externally with a broad flange at the bottom and peripheral ratchet-like notches at the top; and (*c*) a strong retaining spring and weaker creep-spring. Until the gun is fired the retaining spring, bearing on the collar of the ferrule, keeps this pressed up against the top of the cavity; above the collar the creep-spring is under a slight compression, but this does not affect the security of the fuze. On discharge, the ferrule, overcoming its retaining spring, sets back over the detonator holder, where its internal spring catches engage under one or other of the peripheral ratchet-notches on the holder. The ferrule, compressed spring and detonator holder are now locked together. Held steady during flight by inertia and the creep-spring, on impact they fly forward on to the needle.

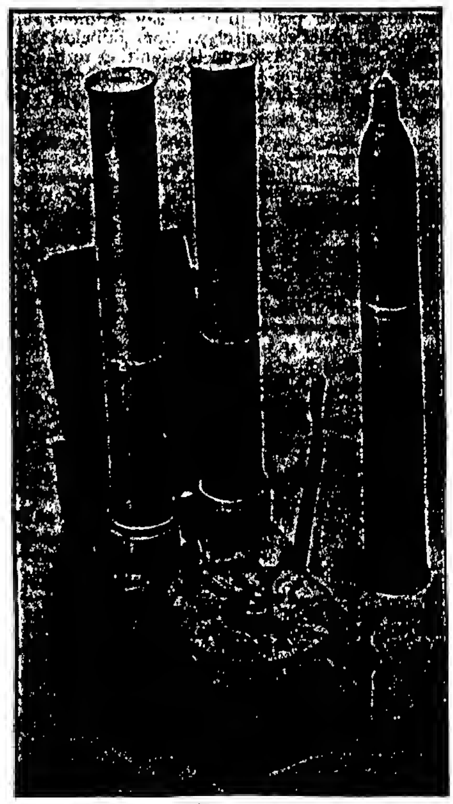

FIG. 21.

In the illustrations, which are diagrammatic, the parts are not to scale, and details (*e.g.* the centring sleeve for the ignition needle pellet) are omitted so as to show the operation of the fuze more clearly.

The construction and operation of the débouchoir or fuze-setting machine are in general terms as follows (figs. 21 and 22):—

A hollow rectangular box contains in its forepart a fixed socket, threaded internally. A second movable socket (the shell holder) is threaded externally in its lower part so as to be screwed up or down

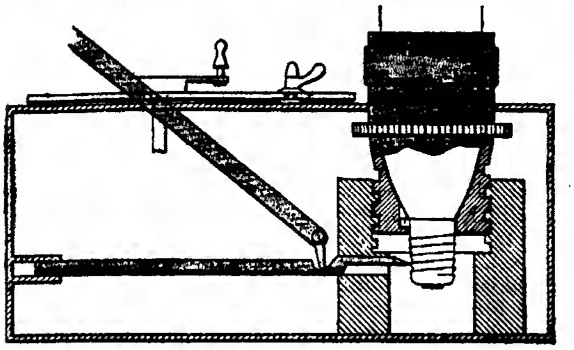

FIG. 22.

in the fixed socket, and formed internally to take the shoulders of the shell, the fuze projecting downwards through a hole in the bottom of the holder. Fixed about the middle of this movable socket is a gear-wheel, and internally, in its bottom, is a small mortise into which a tenon on the fuze engages so that the fuze and shell always occupy a fixed position in the holder. The shell is inserted nose downwards in the holder, secured by the mortise and tenon, and the holder is then, by means of suitable gear in the box operating the gear-wheel, screwed down into the fixed socket, carrying with it the shell and fuze, until the appropriate point in the worm scale of the fuze comes opposite a punching tool in the fixed socket, at which point the tool, operated by an external hand lever, punches the cover, lead tube and body as before described. The amount of screwing-in is determined by the number of turns (or fractions of a turn) of the holder gear-wheel, and the internal gear of the box which actuates this gear-wheel is so controlled by a handle on the top of the box that the position of the handle relatively to a dial[1] on the box exactly represents the position of the fuze scale relatively to the punching tool in the fixed socket. (In practice the handle is set and the holder socket screwed in first, the shell inserted and keyed next, and the actual punching comes last.)

The French service débouchoir is made with two sets of elements side by side having a common dial, corrector scale and setting handle, but separate punching handles. This enables two fuzed shells to be set simultaneously for the same time of burning or successively for different times as desired.

AUTHORITIES.—No recent book descriptive of fuzes has been published, in the ordinary sense of the word. Information during the war period was circulated only amongst those professionally concerned. The information given above has been collected from various papers and memoranda of this kind, and chiefly from those supplied by the authorities of Woolwich Arsenal, to whom, and to Lt.-Col. G. O. Boase in particular, thanks are due. (C. F. A.)

MACHINE GUN, RIFLE AND PISTOL

Since 1910 rapid strides have been made in the improvement of old and development of new designs of ammunition for machine guns, rifles and pistols, principally due to the World War. The manufacture of small arms ammunition, used by the various nations, may be briefly described by outlining the operations necessary to produce a standard cartridge of any one country. In general, these operations would apply to the manufacture of any cartridge, although slight departures therefrom would be necessary where the designs vary. The metallic components of a cartridge are the case, primer (without chemical composition) and bullet.

The Cartridge Case is made of cartridge brass which, as produced commercially, contains about 67% copper and 33% zinc. The brass is furnished in strips, coiled in convenient lengths, which are passed through automatic machines to produce metallic cups, from which the finished cases are evolved by a series of processes generally similar to those described for heavy gun cartridge cases.

The Primer, inserted in the head of the cartridge case, consists of a cap made of primer brass into which is inserted a percussion composition usually weighing from ·25 to ·40 grain, according to the character of the composition. After the assembly of the components, the primer is subjected to a drying operation for a short time to insure that no moisture remains in the chemical mixture. After inspection it is inserted into the primer pocket and a drop of shellac placed in the joint between the primer and the cartridge case to provide water-proofing.

The Bullet (unless it be of special type such as armour-piercing) consists of a jacket surrounding a core. This jacket is made from cupro-nickel which, as furnished commercially, contains from 80% to 85% copper and from 15% to 20% nickel. The cupro-nickel is furnished in coiled strips from which by automatic machines cups are produced. These cups are subjected to a series of drawing operations after which the nose and profile of the bullet are formed by swedging processes. The core, of lead hardened with antimony or tin, may or may not be inserted before the bullet jacket is swedged to form. Finally, the composite bullet is resized and prepared for union with the cartridge case.

In assembling the complete round the primed cartridge cases are shellacked in the mouth for water-proofing, and are loaded by automatic machines with a propellant powder charge weighing from 40 to 50 grains. The bullets are then inserted into the mouths of the cartridge cases and secured by crimping the top edges of the cases into the cannelures provided (or otherwise, according to the design of the cartridge in question). Small arms ammunition of the various countries is designed and loaded to give muzzle velocities varying from 2,200 to 2,800 ft. per second, with maximum pressures never exceeding 60,000 lb. (27 tons) per sq. inch. Cartridge clips for quick loading are used in some form with practically all magazine rifles. The number of cartridges in a clip is usually five, placed one above the other. These clips are usually made with a body of rust-proofed steel or brass containing a flat brass spring.

The loaded ammunition, after being weighed, inspected and clipped, is classified and packed according to its future use. In the United States, ammunition passed as suitable for both rifles and ground machine guns is packed for issue in bandoleers made of olive-drab cloth, which generally contain six boxes each holding two clips. In most armies such individual packets of ammunition are put up in larger, metal-lined boxes, the number of rounds packed in a box and therefore its weight varying in different countries according to the preferences of the military authorities in each.

Packing-boxes are provided with watertight metal liners. In the United States the packing-box when loaded with ammunition weighs approximately 110 lb.; in Great Britain (mark VII. ammunition), 75 to 80 lb.

Ammunition for Machine Guns may be divided into two general classes: first, that for use in machine guns on the ground; and second, that for use in aircraft machine guns. The extensive use of ammunition for machine guns in the World War involved no new processes of manufacture in order to adapt it to the particular weapons. It did, however, require a more rigid inspection system in order to insure that the ammunition produced was of a quality suitable to stand the wear and tear of machine-gun action.

Ammunition for ground machine guns is generally the same as the standard type used in the shoulder rifle, but more rigidly inspected and tested. Several of the belligerents in the World War developed special types of cartridges having heavier bullets than their standard types for use in machine-gun barrage fire.

A number of special types of machine-gun ammunition have been developed for use by aircraft, all of which have the same overall length as the service ammunition and may be briefly described as follows:—

The *tracer cartridge*, as the name implies, is loaded with a tracer bullet for use with machine guns where, as in aircraft work, it is essential to make the trajectory visible. The bullet differs materially from that of the service cartridge, in that the lead core of the latter is replaced by a conical lead slug in the nose of the tracer bullet jacket, in the rear of which there is inserted a gilding-metal capsule which contains the tracer composition. The ingredients used in the composition are dependent upon the type of trace desired. The red tracer involves the use of strontium salts with the necessary oxidizing agents, while the so-called white tracer gives off a greenish-white flame and involves the use of the barium salts with oxidizing agents. The tracer composition is compressed into the capsule at a pressure to withstand that produced by the exploding cartridge and the length of trace can be regulated by the adjustment of the pressure or amount of oxidizing agents used in the chemical mixture. The composition is ignited by the propellant powder flash and burns with a bright light during a minimum of 500 yd. of flight. Tracer cartridges are generally loaded so as to give the same ballistics as the service ammunition at 500 yards. As these cartridges are placed in machine-gun belts, interspersed with service, incendiary and other types of special aircraft ammunition, a distinctive marking is provided so that inspection may be made of each ammunition belt before the aviator goes into the air.

Owing to the extensive use of observation balloons and dirigibles in the war, the demand was created for an *incendiary bullet* which

[1] The zero of this dial is itself adjustable relatively to a fixed fuze-corrector scale. For the theory of the corrector *see* 2.692, par. 29 and footnote.

would ignite gases or other materials with which it might come in contact. Omitting technical detail, this form of bullet is organized to contain a charge of yellow phosphorus coated with copper phosphide or aluminium dust in the head. The base is sealed, but a small hole is punched in the side of the bullet and closed with an easily fusible alloy containing a high percentage of bismuth. The heat generated by the passage of the bullet through the barrel of the gun causes this alloy to melt, at the same time causing the yellow phosphorus to become molten. Upon exit from the barrel, the centrifugal force produced by the spinning of the bullet throws the molten phosphorus through the side hole and upon contact with the air the phosphorus burns leaving a trail of smoke and fire streaming from the bullet. Incendiary bullets burn over a range of approximately 300 yd. and are so loaded as to shoot similarly to service ammunition at that range. Incendiary cartridges are distinguished from other types of ammunition by special markings.

The use of various standard-calibre incendiary bullets against observation balloons and dirigibles was supplemented by the development of a larger calibre (11 mm.) *tracer incendiary cartridge* for use at longer ranges. The bullets are generally turned out of solid brass rod and are approximately 1·34 in. long. The tracer incendiary composition produces a white or a red flame according to the chemicals used. This composition is mixed and compressed into the brass bullets so as to withstand the pressure of the cartridge when fired. The flame from the propellant ignites the composition, which burns for at least 1,200 yards. The cartridge case is of the rim type and is loaded with a propellant to give a muzzle velocity of 2,000 to 2,350 ft. per second.

Combinations of the various types of bullets described above have been tried out experimentally with different degrees of success. The inspection of all of these types is very rigid, as all ammunition for aircraft use must be specially selected, in particular because hang-fires may be dangerous in aircraft machine guns synchronized with the propeller.

Many types of *armour-piercing bullets* were used during the World War in order to attack the light armour-plate of aeroplanes, tanks, etc. This class of bullet, with its steel core, required considerable experimental work and may still be considered as in the development stage. It consists principally of a cupro-nickel jacket, inside which is a hardened steel core incased in a lead envelope. The action may be briefly described as follows:—

Upon striking the armour-plate, the jacket splits and a portion of the lead in the nose of the bullet is trapped between the hardened point of the steel core and the surface of the hardened armour-plate. This soft mass of lead produces a protective coating for the nose of the steel core and thus aids penetration. The bullet is loaded into the same case as the service ammunition and is distinguished by special markings. A larger calibre of armour-piercing ammunition was developed by the Germans for the 13-mm. anti-tank rifle (*see* RIFLES). The bullet was of the armour-piercing type and weighed approximately 800 grains, while the cartridge case was of the semi-rimless type with a propellant charge of about 200 grains. This cartridge developed a muzzle velocity of about 2,450 f.s. and was very effective against tank armour. Further developments along this line may be expected in the future.

Ammunition for Rifles.—Each country has its standard rifle cartridge which is of the same shape and size and is manufactured in the same manner as the machine-gun ammunition above described. Some of these cartridges are of the rimmed while others are of the rimless type. The standard calibres vary from ·25 in. to ·32 inch. Various other types have been developed for guard, test, and training purposes, such as the blank, dummy, guard, high-pressure, and gallery-practice cartridges.

Ammunition for Pistols.—The ammunition used in various countries in automatic pistols is very similar, and a description of the manufacture of the United States type may be considered to be representative of all others. This cartridge consists of a drawn brass case with a primer inserted in its head. The bullets, as a rule, have jackets made from drawn gilding metal or some other suitable material. The manufacture of the cartridge case and bullet-jacket follows, in general, the process outlined for the manufacture of the rifle-cartridge components except that the number of operations is considerably reduced. The bullet is ·45 calibre, weighs 230 grains and has its jacket tinned and filled with a core of lead hardened with about 2% of antimony. The cartridge cases are all of the rimless type and have a small cannelure located on the cartridge case in such a position as to prevent a bullet from being pushed back into it. All pistol ammunition is loaded to give low velocities as compared with rifle ammunition. Calibre ·45 cartridge, used by the United States, has a muzzle velocity of 800 f.s. and develops a maximum pressure of 16,000 lb. per sq. inch. In addition to the pistol cartridges of the service type, there are blank and high-pressure cartridges for instructional and testing purposes. The ammunition made for automatic pistols of smaller calibre, used by travellers, police and others, is in principle similar to that of the heavier ·45 pistol. (W. L. C.)

AMUNDSEN, ROALD (1872–), Norwegian polar explorer, was born at Borge, Smaalenene, Norway, July 16 1872, the son of a shipowner. He was educated at Christiania and afterwards studied medicine for two years. Later, however, he went to sea, and from 1897 to 1899 served as mate on the "Belgica" with Capt. Adrien de Gerlache's Antarctic expedition. In 1901–2 he made an expedition to the Arctic regions which resulted in some valuable observations, and from 1903 to 1906 was in command of the "Gjöa" on its voyage through the north-west passage between the Arctic and Pacific oceans (*see* 21.953). The "Gjöa" made a second Arctic expedition between 1910 and 1912. Towards the end of 1910 Amundsen started in Nansen's famous ship, the "Fram," for the Antarctic regions. The polar continent was crossed under good conditions, the weather being excellent, while the arrangements for food and transport worked without a hitch. The South Pole was reached between Dec. 14 and 17 1911, the Norwegian party thus outstripping by about a month the British expedition led by Capt. Scott (*see* ANTARCTIC REGIONS). In June 1918 Amundsen left Norway in the "Maud" with the intention of drifting across the Arctic ocean, but at the end of 1919 was forced to abandon the attempt (*see* ARCTIC REGIONS). Capt. Amundsen has published *The North-West Passage* (1907), and *The South Pole* (1912), and has received many honours from learned societies.

ANAESTHETICS (*see* 1.907).—In connexion with the progress made in 1910–20, it is somewhat remarkable that the agents for producing general surgical anaesthesia which were the first to be introduced, that is, nitrous oxide gas, ether and chloroform, not only remained in general use, but actually provided in greater part for the requirements of modern surgery. "Regional" anaesthesia, or analgesia as some prefer to call it, had, however, in part supplanted "general" anaesthesia. It consists in abolishing sensation in a restricted part of the body without affecting consciousness; it is effected by "blocking" the conduction of sensation through the nerves supplying the area concerned by applying to them a solution of a drug similar in constitution to cocaine, or by injecting this solution into the lower part of the spinal canal and so blocking the sensory fibres in the nerve roots and in the spinal cord itself. Regional anaesthesia has, however, as yet only a limited application, for although adopted as a convenient routine measure in some classes of cases and types of patients, yet it has been found by experience to have certain limitations, and in the case of spinal anaesthesia certain dangers. Many persons, moreover, prefer the blissful ignorance of a general anaesthesia to full consciousness, and passive submission to a trying ordeal, even when they are deprived of sensation and when the sight of the operation is hidden from them.

General anaesthesia produced by the inhalation of a gas or vapour remains the routine procedure. The use of non-volatile drugs, such as morphia or hedonal, introduced by the mouth or by subcutaneous or intravenous injection, is not readily subject to control; once introduced these substances remain in the body until slowly excreted by the kidneys; the dose can be increased but it cannot be decreased, and herein lies a danger. Inhalation anaesthesia on the other hand is susceptible of the most delicate adjustment to requirements. The pulmonary route is adapted anatomically to meet the vital requirements of the absorption and excretion of the blood gases, oxygen and carbon dioxide, and is hence perfectly adapted for the passage to and from the blood of other gases and vapours. The amount of a vapour absorbed by the blood and the rapidity of its absorption are both proportional to its concentration in the atmosphere inhaled into the lungs[1] so that the task of the anaesthetist is mainly one of adjusting the strength of the vapour according to the result which is desired. So also the amount which has been introduced into the blood can be rapidly reduced; it is partially exhaled on diminishing the strength of the vapour presented to the blood, and it becomes totally exhaled on withdrawing the vapour entirely from the inhaled atmosphere. This facility of the adjustment of anaesthesia is not shared by any other method, and it appears likely to sustain inhalation anaesthesia in its present predominant position for some time to come.

[1] In the case of chloroform there is a deviation from the laws of the solution of vapours, but this is negligible at the low concentrations employed for anaesthetic purposes.

Nitrous Oxide.—One of the surgical lessons of the World War was that persons suffering from severe shock and loss of blood from wounds did not progress favourably following operation under chloroform or ether, but that the prospects of recovery were distinctly improved when performed under the continuous inhalation of nitrous oxide gas. The reasons for this cannot be stated precisely, but it may be said in general terms that nitrous oxide is less depressing, and further that owing to its exceedingly rapid excretion, consciousness and normal bodily conditions are quickly restored after completion of the operation.

Nitrous oxide, or "laughing gas" as it was formerly termed, is familiar as an agent for producing brief periods of narcosis, as for the extraction of teeth. When administered thus in a pure state it excludes the admission of air to the lungs, and if continued would cause complete asphyxia; the problem of continuous administration is therefore the admission of sufficient oxygen to the lungs to satisfy the needs of the body. Air contains about one-fifth of its volume of oxygen, but if nitrous oxide were diluted to this extent its partial pressure would be reduced to about 80%, which is too weak for the convenient production of its full anaesthetic effect, at least in the early stages of its administration. It is possible, however, to reduce the amount of oxygen inhaled below the normal quantity without reducing the oxygen in the blood to the same degree; this is due to the fact that the absorption of oxygen by the blood is a process of loose chemical combination with the haemoglobin, which is not governed by the laws of the simple solution of gases. Oxygen may in fact be reduced to a proportion of one-tenth of an atmosphere without causing discomfort to the patient or even under ordinary circumstances causing the discolouration of the face known as cyanosis. It may even be reduced lower than one-tenth and yet be capable of sustaining life. The continuous administration of nitrous oxide mixed with oxygen is thus made possible by the provision of a sufficiently delicate mechanism to regulate and indicate the relative proportions of the gases. One form of indicator which has been generally adopted consists of pressure dials connected with the supply tubes from the cylinders of compressed gases; these register the pressures at which the gases are supplied, and the proportions are in the same relation as the pressure of flow. Another form of indicator is that known as a "sight-feed," in which the gases bubble through a glass vessel containing water, the flow being regulated so that one bubble of oxygen passes for a given number of nitrous oxide bubbles according to desire.

The continuous administration of nitrous oxide and oxygen is not, however, a method which is adapted for all classes of cases; the relaxation of the body muscles is not sufficient for the convenient performance of certain operations; the narcosis is not always sufficiently deep, and it may have to be supplemented by an admixture of ether vapour; nor is it a method absolutely free from danger. Its advantages in the cases of profound shock referred to appear to be undoubted, but how far it can be adapted for general purposes is as yet undecided.

Ether.—The use of ether as an anaesthetic has received considerable stimulus from the introduction of the "open" method of administration. In order to induce anaesthesia in a muscular person, or to "get him under" in ordinary phraseology, a strong vapour may be required, as strong as 25% to 30% in some cases, and it was formerly supposed to be impossible to attain sufficient concentration from ether sprinkled on a piece of fabric stretched on a frame or "mask." In order to attain this end a "close" method has been in general use, in which the patient breathes to and from a rubber bag over a surface of ether. In this way the vapour becomes concentrated in the bag, but at the expense of the oxygen of the contained air, which becomes rapidly used up, so that the inhaler must be removed periodically to allow of an inspiration of pure air in order to obviate total asphyxia. This method is effective, but far from ideal; the patient is generally more or less "blue" from partial asphyxia throughout the administration, there is a profuse secretion of slimy mucus which must be continually wiped away, the respirations are greatly exaggerated from "re-breathing" the carbon dioxide which accumulates in the bag, and they are often at the same time partially obstructed from the pressure of the closely fitting face-piece. The after-effects are generally unpleasant and not infrequently distressing.

In the "open" ether method the breathing is noiseless, effortless, and only slightly exaggerated, so that delicate abdominal operations can be performed with comfort. The flow of saliva is considerably less than in the closed method (probably from the absence of asphyxia) and this can be entirely abolished by the subcutaneous injection of a minute dose of atropine previous to the administration. There is no sign of cyanosis, and the patient's face remains a healthy colour throughout; the only restriction of oxygen is by reason of the displacement of air by ether vapour which at a maximum will be less than one-third its volume, and as in the later stages of an administration much less vapour is required the restriction becomes entirely negligible. The after-effects of ether, such as vomiting and malaise, are considerably less pronounced than following a "close" administration.

The application of the "open" method to ether inhalation has been brought about by an exceedingly simple adaptation. The liquid ether is applied to a pad of open-wove fabric, such as "stockinette" or a number of layers of absorbent gauze, stretched over a framework mask of which the margin is roughly adapted to the contours of the face; the mask rests lightly upon the face, a soft pad being interposed between its edges and the skin to prevent the entrance of air in this direction. In this way the inhaled air is made to pass through the meshes of the fabric, and in doing so every portion of it comes in close contact with the ether, and takes up a greater proportion of vapour than it would if it merely passed over the surface of the fabric, as in the ordinary way of procedure.

The induction of anaesthesia by the open method is liable to be somewhat prolonged, an undoubted disadvantage, but once full anaesthesia has been produced it is maintained without difficulty, and the results attained are in general more satisfactory than those of any other form of inhalation anaesthesia.

The "intratracheal" method of etherization has in recent years been in considerable requisition for special purposes. It is conducted by passing a narrow tube through the larynx into the trachea almost to the level of its bifurcation. Through this tube a continuous current of air and ether vapour is forced into the lungs at a pressure which keeps the lungs moderately distended, but not so much so as to abolish the natural respiratory movements. The air returns through the chink of the vocal cords by the side of the tube, and this continuous return blast blows away any solid or fluid particles, blood or pieces of tissue, in the neighbourhood, and prevents their entering the trachea, an accident which may possibly occur in ordinary inhalation methods. The advantage of intratracheal ether in operations involving the respiratory passages is therefore obvious; it is likewise a convenient arrangement for operations upon the face, which is left entirely uncovered; and in operations upon the interior of the thorax a proper aeration of the lungs can be thus insured.

Chloroform.—The form of sudden death which is occasionally encountered under chloroform anaesthesia has acted as a deterrent to its more extended employment in spite of its manifest conveniences. An earnest endeavour was made by an influential committee appointed by the British Medical Association to find a method of preventing these chloroform deaths, by enquiring into the conditions of overdosage and devising apparatus for the precise limitation of chloroform vapour to essential requirements. The final report of this committee was issued in 1910, but the number of deaths from chloroform has remained practically undiminished since that time. An attempt has further been made to reduce the risk of overdosage by diluting the chloroform with ether in varying proportions, but this has proved to be futile as a prophylactic against death, for although the number of deaths under pure chloroform has fallen, the number under mixtures of chloroform has risen ten times in a period of ten years.

It is now becoming realized that the typical sudden chloroform fatality is not conditioned by an overdose at all. It has long been known that the majority of deaths occur in the very early stages of anaesthesia before the patient is fully narcotized, and further enquiry into reports of fatalities shows that there is generally some evidence of light anaesthesia preceding death, or else that overdosage can be ruled out of question.

There is a further point brought out by these reports, which was in fact fully appreciated by John Snow in the middle of the last century: whereas in overdose the respiration is paralyzed before the circulation, in the typical chloroform death the outstanding feature is an absolutely sudden failure of the circulation, and the failure of the respiration is a secondary result.

In 1890, Dr. Robert Kirk, boldly and with strong conviction, advanced the theory that chloroform deaths occurred from underdosage, and although his thesis was supported by important experiments, he failed to formulate an acceptable theoretical basis for it. Dr. A. G. Levy, in 1911, reported certain cases of sudden cardiac failure that he had observed in animals obviously in a light stage of chloroform anaesthesia, and he succeeded in reproducing this death by the intravenous injection of small doses of adrenalin in lightly chloroformed animals, but the experiment failed under full chloroform narcosis. This at once accounted for those cases of syncope and death, a number of which had been recorded, following the injection of adrenalin into the mucous membrane of the nose for the purposes of certain nasal operations which were always conducted under light anaesthesia, the form of this syncope being the same as in an ordinary chloroform fatality.

By following up this line of research it was shown that sudden cardiac failure could be induced likewise by various procedures—excitation of the cardiac accelerator nerves either directly or through a reflex mechanism, stimulating the excretion of the adrenal glands, by intermitting the administration of chloroform, or by withholding the chloroform during excitement and struggling; the event never occurred during deep narcosis. The underlying condition of the cardiac syncope was shown to be that of fibrillation of the ventricles, in which the ventricles are entirely deprived of their power of propelling the blood through the arteries. The seeming paradox of too small a quantity of a drug being dangerous is susceptible of explanation although the theoretical points have not been fully worked out: a relatively small proportion of chloroform renders the heart "irritable" and liable to assume a sequence of irregular beats which may pass into fibrillation, whereas a larger proportion of chloroform, by reason of its depressing effect, makes

the heart less irritable, and entirely annuls the tendency to fibrillation.

Many years ago J. A. McWilliam expressed the opinion that ventricular fibrillation would be found to account for otherwise unexplained sudden death met with in various conditions, and this demonstration of its occurrence under chloroform is the first confirmation of his views.

On this theory the prevention of death under chloroform can be compassed by simple precautions, by making the induction of anaesthesia continuous and expeditious and thereafter continuously maintaining a full degree of narcosis. Chloroform should never be employed if the conditions of the operation forbid the observance of these rules, and especially in those special cases in which a light degree of anaesthesia is required. These rules are practically a reversion to the injunctions of Simpson, who introduced chloroform as an anaesthetic, and his colleague Syme, in whose experience only one case of death occurred in 10,000 administrations.

Ventricular fibrillation is not always fatal; probably in more than half the cases the heart spontaneously recovers its normal beat, but this happy result can only occur in the first minute or two following the onset of fibrillation. After that time the only prospect of recovery is through the performance of cardiac "massage." This so-called "massage" is a rhythmic manual compression of the heart, producing an artificial circulation; it is combined with an artificial ventilation of the lungs, and so oxygenated blood is supplied to the heart muscle keeping it alive and active, and giving to it a prolonged chance of recovery. In cats this experiment is uniformly successful in bringing about recovery, but in man there have hitherto been only relatively few successes. It appears to be the case that failures have arisen from an imperfect appreciation and application of the principles of cardiac massage, and it is believed that with better knowledge the majority of cases of ventricular fibrillation should prove amenable to this form of treatment.

(A. G. L.)

ANCONA, ALESSANDRO (1835–1914), Italian man of letters (*see* 1.951), died at Florence Nov. 8 1914. In 1904 he had been made a senator. Many of the most eminent contemporary philologists and students of literary history in Italy had been his pupils.

ANDERSON, ELIZABETH GARRETT (1836–1917), English medical practitioner (*see* 1.950), died at Aldeburgh, Suff., Dec. 17 1917.

ANDERSON, SIR ROBERT ROWAND (1834–1921), British architect, was born at Forres in 1834, the son of a solicitor. He was educated at Edinburgh and entered the Royal Engineers, where he received his first training as a draughtsman. He subsequently travelled widely in Europe, and later adopted the profession of architect. His first important work was his successful design for the Edinburgh Medical Schools (1875), and this was followed by a succession of important commissions, including those for the offices of the Caledonian railway, Glasgow, and Mount Stuart, Lord Bute's house on the island of Bute (1881–4), the Conservative Club, Edinburgh (1883), the dome of Edinburgh University (1886) and the Scottish National Portrait Gallery (1886–8). He also successfully carried out a series of restorations of Scottish cathedrals, including those of Dunblane Cathedral, Paisley Abbey, Culross Abbey and the interior of Dunfermline Abbey. Many of the best-known monuments in Edinburgh are from his designs, and he was among the architects invited to submit designs for the Imperial Institute (1887), the Queen Victoria Memorial (1901), and the new buildings of the British Museum (1904). In 1901 he was selected to superintend the alterations which were being carried out at Balmoral Castle, and in 1902 he was knighted. Sir Rowand Anderson was in 1876 elected an associate of the Royal Scottish Academy, of which he was in 1896 elected an honorary member. He was also member of the Royal Institute of British Architects and in 1916 was awarded the Royal gold medal for the promotion of architecture. He died at Edinburgh June 1 1921.

ANDORRA (*see* 1.965) had, in 1913, a pop. of 5,210, distributed in 6 communes embracing 44 villages and hamlets. Alt. ranges from 6,562 ft. to 10,171 ft.; alt. of Andorra la Vella, the capital, 7,500 feet. The trans-Pyreneean railway from Ax-les-Thermes (Chemin de Fer du Midi) to Ripoll will pass within 2 or 3 m. of the frontier. A motor road, made by the French from Ax over the Col de Puymorens (alt. about 6,300 ft.) to Bourg-Madame on the Spanish frontier, is tapped by a branch road (under construction in 1912) entering Andorra at Port d'En-Valira (alt. 7,580 ft.), and running down the Valira valley to the capital.

The revenue of the republic, amounting to about 32,000 pesetas per annum, is derived from the sale of wood from the state forests, the rental of summer pastures, a tax on inns and slaughter-houses, a small tax on cattle and a poll-tax. The two suzerain powers receive a biennial tribute—France 1,920 francs and the Bishop of Urgel 920 pesetas; the latter also receives annual gifts in kind from each of the six communes. The principal industry is the raising of cattle, sheep and mules. There is a small tobacco factory at the capital and a considerable amount, of poor quality, is exported to Spain. Wax matches are also made. French and Spanish postage stamps, for the north and south respectively, are in use; the telegraphic arrangements are French. Both French and Spanish coins are current. France has established schools in Andorra, and French influence is in the ascendent.

ANDRASSY, JULIUS, Count (1860–), Hungarian statesman, son of the former Minister of the Interior, was born June 30 1860. Deputy (1885), Secretary of State for the Interior (1892), Minister of the Court (1892), he became Minister of the Interior in 1906. As Minister of the Interior, as well as earlier in connexion with the language of command in the Hungarian army and against the régime of Fejervary, he maintained a severe struggle with the prime ministers Khuen-Hedervary and Stephen Tisza. In 1913 he delivered three speeches in the Hungarian Delegation against the conduct of foreign affairs. and in Parliament he opposed the plan for the centralization of the internal administration of Hungary. At the outbreak of the World War he supported the Tisza ministry, but opposed Burian, the Foreign Minister, on the Polish and the Italian questions. In 1915 he pleaded for peace, and urged a wide extension of the franchise. In 1918, as Foreign Minister, he declared the alliance with Germany dissolved, and desired to conclude a separate peace. He retired from office on Nov. 5. was returned for Miskolcz to the National Assembly in Jan. 1920 as a non-party delegate, and later became leader of the Christian National party. In 1904 he was made an associate of the Hungarian Academy of Sciences, in recognition of his distinguished work as a historian.

His works include: *Ungarns Ausgleich vom Jahre 1867* (Hungarian and German, crowned by the Academy); *Die Ursachen des Bestandes des Ungarischen Staates und dessen verfassungsmässiger Freiheit* (3 vols., Hungarian, crowned by the Academy); *The Development of Hungarian Constitutional Liberty* (English); and in Hungarian and German *Wer hat den Krieg verbrochen? Interessensolidarität des Deutschtums und Ungartums* and *Diplomatie und Weltkrieg*. (E. v. W.)

ANDREE, RICHARD (1835–1912), German geographer (*see* 1.971), died at Leipzig Feb. 22 1912.

ANGELL, JAMES ROWLAND (1869–), American educationist, was born at Burlington, Vt., May 8 1869. He was a son of James Burrill Angell (d. 1916), first president of the university of Vermont and fourth president of the university of Michigan (1871–1901). He was educated at the universities of Michigan (A.B. 1890; A.M. 1891) and Harvard (A.M. 1892), and spent a year in Europe, chiefly at Berlin and Halle. In 1913 he was appointed instructor in philosophy at the university of Minnesota. In 1894 he was called to the university of Chicago, remaining there until 1920, as assistant professor of psychology and director of the psychological laboratory, associate professor and, after 1905, professor and head of the department. He was dean of the university faculties after 1911 and acting president during 1918–9. In 1906 he was elected president of the American Psychological Association, in 1914 was exchange professor at the Sorbonne, and in 1915 was special lecturer on psychology at Columbia. After America entered the World War in 1917 he was connected with the adjutant-general's office as member of the committee on classification of personnel in the army. He was also a member of the National Research Council, serving as chairman during 1919–20. In April 1920 he was elected president of the Carnegie Corporation of New York. In 1921 he was elected president of Yale to succeed Arthur T. Hadley, resigned.

He was the author of *Psychology* (1904; 4th ed. revised, 1908); *Chapters from Modern Philosophy* (1912) and *An Introduction to Psychology* (1918).

ANGOLA (Portuguese West Africa) (*see* 2.38).—A census taken in 1914 gave the pop. as 2,124,000, but this total was based on figures supplied by the natives for the purpose of a hut tax,

and did not include regions over which the Portuguese exercised no authority. In 1920 the pop. was estimated, with greater accuracy, at a little under 4,000,000, or eight persons per sq. mile. There were some 30,000 whites, mostly Portuguese. Loanda (São Paolo de Loanda), the capital, had 18,000 inhabitants, of whom a third were whites.

Surveys made since 1909 showed that the part of southern Angola suitable for European colonization was larger than had been supposed and that the plateau, which is free from tsetse-fly, was well adapted to stock raising. Few settlers had been, however, attracted to this region up to 1921 and the development of the whole province was very slow. There was nevertheless an increase in cocoa plantations, chiefly in the Kabinda enclave; coffee, though gathered mainly from wild plants, was also cultivated in the Loanda hinterland and other areas. Rubber was obtained mostly from virgin forest, but ceara, ficus and other trees were planted. Up to 1911 the manufacture of rum was the leading industry; in that year the factories were closed by Government decree, compensation being given to the factory owners and to the planters who grew sugar and sweet potatoes for the production of alcohol. These planters were encouraged to grow sugar-cane for export, and the output for 1913 was 4,600 tons. Subsequently the industry languished. Fish-curing and whaling are lucrative industries. The whalers are Norwegians and Americans and their headquarters are at Lobito Bay. Forestry and mining are both undeveloped, but the syndicate which since 1908 has worked the Kasai diamond area of the Belgian Congo has also concessions on the Portuguese side, and in 1920 the output of diamonds from Angola was estimated at 120,000 carats.

External trade, owing to high protective tariffs, was mainly with Portugal; in the period of 1910–20 it was valued at from £3,500,000 to £4,500,000 yearly, with a tendency for exports to decrease. Rubber, coffee, wax, sugar and palm-kernels, dried fish and whale oil are the chief exports.

Lack of means of transport was a principal cause of the slow progress of Angola. The most important railway (of the standard South African 3 ft.-6 in. gauge), that from Lobito Bay by Benguella across the southern plateau, had reached Bihe, a distance of 323 m. in 1914, when owing to the World War construction stopped. The railway, a British enterprise, was designed to serve the copper mines of Katanga, Belgian Congo, and work on the remaining 480 m. to the Congo frontier began in 1921. A British company acquired large land concessions along the line and started ranches. Farther south a narrow gauge (60 cm.) railway 111 m. long goes from Mossamedes to the Chala Mts., serving a wheat-growing region with European settlements, including one of South African Dutch. In northern Angola the railway (metre gauge) from Loanda was carried to Malanje (375 m.) and was bought in July 1918 by the Portuguese Government.

Excess of expenditure over revenue continued to be a characteristic of the administration, partly because, except for a hut tax on natives, there was no direct taxation. Revenue was almost entirely derived from import and export duties. Deficits were made good by grants made from Portugal and by transfers from the treasuries of such Portuguese colonies as showed an excess of revenue. Annual revenue averaged, on a rough estimate, £500,000 and expenditure £700,000.

History.—Southern Angola, in 1909–11, was regarded as a probable choice by the Jewish Territorial Association as a field for colonization, and Portugal enacted land laws with a view to that contingency. But Angola was rejected by the Zionists as a home for Jews. Between 1910 and 1914 chief interest in Angola centred in a very different scheme—the efforts of Germany to include the province in her economic and, ultimately, her political sphere. As far back as 1898 Great Britain had recognized Germany's right to "assist" the Portuguese to exploit southern Angola, but this had not prevented a British syndicate under Mr. Robert Williams from securing the concession for the Benguella (Lobito Bay) railway. On the building of this line from the coast to Bihe over £5,000,000 was spent. A new Anglo-German agreement had been negotiated in 1913–4 and only awaited signature when the World War put an end to the negotiations. The new treaty would have recognized German economic interests as supreme throughout Angola, except in its eastern section (*see* AFRICA: *History*). Meantime the Germans had pressed the Portuguese, and with some success, to grant them commercial concessions, and had made offers to buy up the British capital (90% of the whole) in the Benguella railway—offers which were rejected.

In southern Angola itself German agents and so-called scientific missions showed much activity. Not only did its highlands present many advantages for European settlement; the Kunene river valley, part of which was in German territory, was inhabited by the Ovambo, of whom some 20,000 were recruited by the Germans for work in the Otavi copper-mines. In 1913 the Portuguese forbade further recruiting in Angola; the Germans replied by presenting estimates to the Reichstag in 1914 for £150,000 towards building a railway from Otavi through the Ovambo country and 22 m. of the railway had been built when the World War began. Though Portugal was at the time neutral several conflicts occurred between the Portuguese and Germans in the frontier district. The surrender of the Germans in South-West Africa to Gen. Botha, in July 1915, removed the German menace to Angola and gave the province the British (South Africans) as neighbours on the south.

In an endeavour to break with the tradition that the colonies existed only for the benefit of Portugal the Lisbon Government in 1914 granted them a measure of autonomy. The then governor-general of Angola, Senhor Norton de Mattos, had already instituted reforms and in 1913 had created a Department for Native Affairs, which set itself to regulate the employment of natives, including the recruitment of labourers for the cocoa plantations on St. Thomé and Principe Islands. The result was some improvement in the conditions of the natives, but the principle of compulsory labour was maintained, and abuses continued. In 1920 Portugal again endeavoured to set its colonial affairs in order. Another autonomy measure was introduced and Senhor Norton de Mattos was again (Oct. 1920) selected to go to Angola, this time as high commissioner with wide powers.

Society. (F. R. C.)

ANNUNZIO, GABRIELE D': *see* D'ANNUNZIO, GABRIELE.

ANSON, SIR WILLIAM REYNELL, 1ST BART. (1843–1914), English jurist (*see* 2.84), died at Oxford June 4 1914. In 1909 he signed the minority report of the Divorce Commission, in company with the Archbishop of York and Sir Lewis Dibdin.

ANTARCTIC REGIONS (*see* 21.960).—The expedition planned by Dr. W. S. Bruce for crossing the Antarctic continent in 1911–2, from Coats Land on the Weddell Sea to McMurdo Sound in the Ross Sea, was not proceeded with, and two American expeditions which were contemplated at the same time did not advance beyond the stage of projects.

Shirase (1910–2).—A Japanese expedition to Edward VII. Land was fitted out under the command of Lt. Shirase in 1910 and left Japan in that year on board the "Kainan Maru." It entered the Ross Sea too late to make a landing, and after wintering in Sydney returned in 1911–2, when a landing was effected on the Barrier in the Bay of Whales on Jan. 16, but no discoveries were reported and no account appears to have been published in any European language.

Amundsen (1910–2).—Capt. Roald Amundsen sailed from Norway in the "Fram" (which had been fitted with internal combustion engines) in Aug. 1910 with the avowed intention of carrying out oceanographical work in the South Atlantic and of proceeding round Cape Horn to Bering Strait, where he proposed to repeat Nansen's drift across the Arctic sea from a more easterly starting-place. The announcement of Peary's attainment of the North Pole in 1909 convinced Amundsen that he could not raise sufficient funds for his proposed five years' absence, and he determined to make a dash for the South Pole in order to raise money for the greater project. His change of plan was announced to the world at Madeira in Sept., and on Jan. 14 1911 the "Fram" was alongside the Barrier in the Bay of Whales, lat. 78° 40′ S. long. 164° W. The 116 Eskimo dogs were landed and a hut, "Framheim," erected on the Barrier 2½ m. inland, the point of departure for the Pole being that originally proposed by Shackleton in 1907. On Feb. 15 1911 the "Fram," under Lt. Thorvald Nilsen with nine men, sailed for an oceanographical circumnavigation, with Buenos Aires as the first port of call. Amundsen started on his first depot-laying journey on Feb. 10, and by April 11 had moved 3 tons of provisions to three

depots in 80°, 81° and 82° S. respectively. A start for the main south journey was made on Sept. 8 but the cold proved too severe (−58° to −75° F.) for the dogs and the party returned to winter quarters for a month. On Oct. 20 1911 (with temp. −5° to −23° F.) Amundsen left again with four companions, Helmer Hansen, Oscar Wisting, Sverre Hassel and Olav Bjaaland, four sledges and 52 dogs. At each original depot they rested a day and gave the dogs a full feed from the stores; but on Nov. 8 they left the depot in lat. 82° S., carrying four months' provisions and travelling about 30 m. a day over the smooth Barrier surface, the men using *ski*. At every degree of latitude the sledges were lightened by forming a depot of provisions for the return journey. On Nov. 9 the mountains of South Victoria Land were sighted, and on the 11th another range of mountains was seen joining the Victoria Land range from the direction of Edward VII. Land, and thus forming the southern boundary of the great flat Barrier surface, which apparently did not extend far beyond lat. 85° S. On Nov. 17 a large depot was left in lat. 85° S. at the base of the Queen Maud range which formed the continuation of the Victoria Land mountains, at a point 200 m. S. of the Beardmore glacier. From this point the climb to the Plateau began through magnificent scenery of glaciers and peaks, the heights of which were estimated as 10,000, 15,000 and even 19,000 feet. A way was found to the summit of the Plateau by the Axel Heiberg glacier which was negotiated by the dogs with much difficulty. Four days were occupied in the ascent to a level stretch at 7,000 ft.; and severe weather compelled a halt at this point for four days more. Here 24 dogs were killed, leaving 18 to work the three sledges. A start due S. was made on Nov. 26 and for two days severe blizzards made it impossible to see the surroundings, but the course lay on a descending gradient. On Nov. 29 a depot with six days' provisions was made at the foot of the Devil's glacier in lat. 86° 21′ S. On Dec. 1 at a height of about 9,000 ft. the way led over a smooth ice surface on which it was impossible to use *ski*, while under the tread it sounded like walking on empty barrels, and both men and dogs frequently broke through the thin crust of ice. This tract, called "The Devil's Ball Room," proved the worst travelling of the whole trip. Next day in lat. 88° S. the highest swell of the Plateau, estimated at 11,000 ft., was passed and in a few days the weather improved, travelling was easy, and on Dec. 14 1911 the position of the South Pole was reached. The total distance from Framheim of about 870 m. was accomplished in 49 days of actual travelling, the average daily distance being 17 miles. After remaining two days at the Pole to secure sufficient observations to fix the position, Amundsen and his party returned to Framheim in 38 days, picking up the depots in succession and making an average of 23 m. per day in fine weather without any untoward incident. The health of the men and the 11 surviving dogs was perfect throughout the 96 days of the double journey. During the absence of the southern party Lt. K. Prestrud with Frederik H. Johansen and Jörgen Stubherud made a journey to Edward VII. Land with two sledges and 14 dogs. They were absent from Framheim (where Lindström the cook was left in charge) from Nov. 8 to Dec. 16 1911 and reached Scott's Nunatak, which was found to reach a height of 1,700 ft. and was covered with thick moss. The "Fram" returned to the Bay of Whales on Jan. 11 1912 and the whole party sailed for home on Jan. 30, after the shortest and most successful expedition which ever wintered in the Antarctic. The one object, the attainment of the Pole, had been accomplished quickly and easily and the meteorological observations were of great value in extending the conclusions of other investigators.

Scott (1910–2).—Capt. Robert F. Scott's expedition, planned with the double purpose of reaching the South Pole and completing the scientific study of the Ross Sea area, reached McMurdo Sound in the "Terra Nova" on Jan. 4 1911 (after seeking in vain for a safe position near Cape Crozier), and erected a commodious wooden house for the main base at Cape Evans on Ross I. about half way between Shackleton's base at Cape Royds and the old "Discovery" headquarters at Hut Point. No polar expedition had been fitted out with greater care for the purpose of scientific research in meteorology, geology, glaciology and biology.

After landing the stores for the main base at Cape Evans the "Terra Nova," under Comm. Harry Pennell, left on Jan. 25 1911, proceeded eastward along the Barrier and, after failing to land on Edward VII. Land, encountered the "Fram" in the Bay of Whales on Feb. 3.

Scott's Northern Party (1911–2).—The eastern party decided to return with news of the Norwegian expedition to Cape Evans, and then to proceed as a northern party to some point beyond Cape North, but this also proved unattainable, and a landing had to be made at Cape Adare on Feb. 18 1911. Here a hut was erected and the northern party, under Comm. Victor L. A. Campbell and including Surg. Gen. Murray Levick, Raymond E. Priestley (geologist and meteorologist) petty-officers G. P. Abbott, F. V. Browning and H. Dickason, were landed with stores and sledges but no dogs. One of Borchgrevink's huts built in 1899 was in good order, the other had been unroofed by a storm but both were serviceable. They passed a stormy winter and confirmed Borchgrevink's conclusion that it was impossible to make any extensive journeys either on the sea-ice, which frequently blew out to sea, or by land from this base. On Jan. 4 1912 the "Terra Nova" returned and took off the party, landing them with six weeks' provisions a few days later in Terra Nova Bay, just S. of Mt. Melbourne, on the lower slopes of which much geological work was done. The ship failed to return in Feb. as expected, and the winter of 1912 had to be passed in an ice cave on Inexpressible I. (about lat. 75° S.), the party subsisting mainly on seal meat cooked over blubber lamps devised with much ingenuity. This winter, spent almost without stores, was a triumph of adaptability to the hardest possible conditions, and although there was much illness the whole party was able to march when a start for Cape Evans was possible on Sept. 30 1912. The Drygalski glacier tongue was crossed and the party made its way southward along the sea-ice close to shore. On Oct. 28 Granite Harbour was reached and stores left there by Griffith Taylor allowed of full rations of good food for the first time for nine months. The remainder of the 70-m. march to Cape Evans was assisted by several depots, and they all arrived at Hut Point on Nov. 6 1912, after triumphing over the most difficult conditions ever yet surmounted in the Antarctic.

Scott's Western Party (1911–2).—During Jan., Feb. and March 1911 Griffith Taylor, with Frank Debenham, Charles S. Wright and P. O. Edgar Evans, made an extensive geological survey and study of the ice phenomenon of the lower valleys of the Western Mountains, from Butter Point southward to the Koettlitz glacier in lat. 78° 20′ S., and after the winter at Cape Evans, Griffith Taylor made a second western trip with Debenham, Lt. Tryggve Gran and P. O. Forde, completing the geological survey of the lower mountain slopes W. of McMurdo Sound from Butter Point northward to Granite Harbour in lat. 76° 50′ S. This journey lasted from Nov. 1911 to Feb. 1912 and was rich in scientific results.

Wilson's Winter Journey (1911).—The finest adventure of the first winter at Cape Evans was the daring journey in solstitial darkness *via* Hut Point to Cape Crozier and back by Dr. Edward A. Wilson, Lt. H. R. Bowers and Mr. Apsley Cherry-Garrard. It lasted for 36 days from June 27 to Aug. 1 1911, and the total distance traversed by man-hauled sledges was over 100 m., giving an average of about 4 m. per day out and 7 m. a day home. During a stay of ten days an effort was made to study the nesting habits of the emperor penguin. This journey was made in the lowest temperature ever experienced in the Antarctic: many days had readings below −60° F. and the worst was as low as −77° F. The snow in places was as granular and hard to pull through as sand, and only one sledge could be moved at a time, so that on some days many hours' work only made 2 m. in distance.

Scott's Journey to the South Pole (1911–2).—The main object of Capt. Scott's expedition being the great southern journey, steps were taken at the earliest date to lay out depots for the main expedition of the following year. The vital point being transport, means had been taken to provide three alternatives to man-haulage. There were landed at Cape Evans 17 Siberian

ponies, 33 Siberian sledge dogs and three motor sledges on the design of which Scott had taken immense pains. The motors were practically useless on account of mechanical defects and were abandoned early in the great march. The health of the animals was a source of unending anxiety and much trouble was experienced in driving them.

The route selected was at first about a day's march to the E. of that taken by Shackleton and consequently far to the E. of that followed by Scott on the "Discovery" expedition, the reason being to get the smooth Barrier ice beyond the influence of the great pressure ridges which disturb the surface near the mountains. But the Plateau was to be reached by Shackleton's way up the Beardmore glacier at which point the tracks converged.

Depots were laid out by Scott in Jan. and Feb. 1911 at Corner Camp in lat. 78° S., Bluff Camp nearly in lat. 79° S. and at One Ton depot which he had hoped to plant in lat. 80° S., but was obliged by circumstances to place in lat. 79° 29′ S. only—a necessity which contributed to the greatest Antarctic disaster on record. In Sept. 1911, when the temperature was usually below -40° F., Scott's second-in-command, Lt. Edward R. A. R. Evans, took additional stores to Corner Camp; but no more distant depots were supplemented before the main southern journey started.

The two motor sledges left Cape Evans on Oct. 24 1911, got over the sea-ice to Hut Point, safely ascended to the Barrier and broke down hopelessly, the first a few miles N. of Corner Camp, the second a few miles S. of Corner Camp on Nov. 3. Thenceforward the southern advance was made by 16 people in three parties of four each, reinforced by two from the motor sledges and two with the dogs, one party ahead breaking the trail, the others following at intervals. Bad weather was experienced, frequent blizzards making the advance difficult. Depots with stores were provided for the returning parties at Mount Hooper in lat. 80° 35′ S. on Nov. 21 (Day and Hooper of the motor party, who had dragged a sledge so far, left to return three days later), at the Mid Barrier in lat. 81° 35′ S., at the South Barrier depot in lat. 82° 47′ S. on Dec. 1 and at the entrance to the Beardmore glacier in lat. 83° 30′ S. on Dec. 10. The last of the ponies had broken down and been shot, and from this point Meares and the dog-teams returned northward. The party of 12 pushed on up the Beardmore glacier with three man-hauled sledges, and after leaving a depot in the middle of the glacier, reached the Plateau at 8,000 ft. on Dec. 21 1911 and left the Upper Glacier depot in lat. 85° 7′ S. Here Dr. Atkinson, Mr. Wright, Mr. Cherry-Garrard and P. O. Keohane returned, and the party of eight went on with two sledges. Ten days later Three Degree depot was formed in lat. 86° 56′ S. and at this point Lt. Evans with Crean and Lashley returned. This party was attacked by scurvy as on the southern march from the "Discovery" in 1902, and Lt. Evans broke down on the Barrier and was only rescued by the heroic exertions of his companions. The southern party—now consisting of five men: Scott, E. A. Wilson, H. R. Bowers, L. E. G. Oates and P. O. E. Evans—made one more depot in lat. 88° 29′ S. and reached the South Pole on Jan. 18 1912, having made 69 marches averaging over 12 m. per day. His diary shows that in the outward journey Scott's mind was full of care and anxiety, while the disappointment of finding by Amundsen's record that he was not first to reach the Pole was a shock from which his spirits seemed never to recover.

The return journey was commenced without delay, but without any help from animal traction it proved too much for the men. Edgar Evans fell ill first and after causing fatal delay, he died on Feb. 17 on the Beardmore glacier. Oates, feeling his strength exhausted, had the heroism to sacrifice himself rather than cause further delay, and he left the tent on March 17 in 79° 50′ S. never to return. The last camp was made in lat. 79° 40′ S., only 11 m. from One Ton depot on March 19, and here during a blizzard which raged for several days Scott, Wilson and Bowers met their fate with heroism, Scott writing to the end. The immediate cause of collapse seems to have been cold, due to the deficiency of oil fuel in the Mount Hooper depot, the reason for which was stated to be evaporation through defective stoppers.

The Winter of 1912 at Cape Evans.—During the absence of the southern party the "Terra Nova" had reached Cape Evans in Feb. 1912 and stores were landed, including seven mules from India and 14 dogs. Dr. Atkinson's party, sent back by Scott from the Beardmore glacier, arrived on Jan. 28, and after seeing to matters at the base, Dr. Atkinson went south with the dog-teams in time to rescue Lt. Evans near Corner Camp on Feb. 22, and as the latter was in a serious condition Atkinson stayed with him until he got him on board the "Terra Nova." Cherry-Garrard and Dimitri took the dog-teams back to One Ton depot to meet Scott, reaching that point on March 4 and remaining until March 10 in weather that made a further advance S. impossible, and they got back to Hut Point on the 16th with great difficulty and in a very bad state. The ship left on March 8 to make a final attempt to relieve Campbell's northern party and did not return, so the base party did not know what had happened either to the northern or southern parties. On March 26 Atkinson with P. O. Keohane set out from Hut Point and got as far as Corner Camp, where he turned, being satisfied that Scott's party must have perished. He made one more journey, though it was now very late in the season, and left two weeks' provisions at Butter Point for the northern party, returning to Hut Point on April 23, the day the sun disappeared for the winter. There were 13 souls in the Cape Evans hut that winter, with Dr. Atkinson in charge, Lt. Evans having returned ill to New Zealand and Dr. G. C. Simpson, whose meteorological work had been of unique value, having gone back to his duties in India. On Oct. 30 1912 the whole party, under Dr. Atkinson, with Mr. C. S. Wright as guide, with seven mules and the dogs, set out from Hut Point, and on Nov. 12 the tent with the bodies of Scott, Wilson and Bowers was discovered in lat. 79° 50′ S., and the records and collections brought back.

During Dec. 1912 a party of six climbed Mt. Erebus, reaching the summit on the 11th, the second occasion of its ascent.

The "Terra Nova" returned on Jan. 18 1913 and a few days later took off the entire party, reaching New Zealand on Feb. 12. The sensation produced by the tragedy of the expedition was profound and a large fund was subscribed for the benefit of the relatives of the dead explorers and for the promotion of polar research. The scientific results of the expedition have been worked up and are of the highest value in all departments.

Australian Expedition (1911–4).—An Australian expedition was fitted out under the command of Dr. (later Sir) Douglas Mawson, with Capt. John King Davis as commander of the ship and second-in-command of the expedition, for the purpose of exploring the coast of Antarctica S. of Australia. The expedition left Hobart in the "Aurora" on Dec. 2 1911, and after landing a party with a wireless installation on Macquarie I. (lat. 55° S.) the ship reached Adelie Land, discovered by D'Urville in 1840, and effected a landing in Commonwealth Bay, the position of which was subsequently fixed by wireless time-signals as lat. 67° S., long. 142° 40′ E. Dr. Mawson with 17 companions was landed here in Jan. 1912. The "Aurora" proceeded westward close along the Antarctic circle. Balleny's Sabrina Land, D'Urville's Côte Clarie and most of the land reported by Wilkes were found not to exist, though an enormous ice-tongue which might well have been taken for part of the continent occupied the position of Termination Land. Just beyond this point Mr. Frank Wild was landed on a new coast called Queen Mary Land in lat. 66° S., long. 94° E., and left with seven companions on Feb. 20 1912, the actual position being on a solid ice-shelf about 17 m. from the high land. The "Aurora" returned to Hobart.

At the main base in Adelie Land autumn sledging proved impossible, and throughout the winter there was a continuous succession of terrific blizzards, wind with an average velocity of 50 m.p.h. for the year, and sometimes with average hourly velocity of over 100 m.p.h. poured torrents of drift snow from the interior into the sea. Only the fact that the hut was buried in the snowdrifts saved it from being carried away. No such weather has been recorded from any other part of the world. In the spring two caverns were excavated in the ice at distances

of about 5 and 12 m. respectively from the hut towards the high inland plateau and were stored with provisions for summer sledging; the use of surface depots like those on the Ross Barrier was impossible owing to the wind. Five sledge parties started simultaneously in Nov. 1912, their paths diverging so as to cover the greatest possible area. The eastern sledging parties under Mr. F. L. Stilwell and C. T. Madigan with Dr. A. L. Maclean and others, mapped the coast and huge glacier tongues as far east as long. 150° 20′ E., reaching the farthest point on Dec. 18. The land, with a surface rising to 3,000 ft. above the sea, extended far to the east and was named George V. Land. It stretched towards Oates Land sighted by the "Terra Nova" of Scott's expedition. Good rock exposures were found containing coal and fossils. The magnetic pole party from the main base, under Lt. R. Bage with E. N. Webb and J. F. Hurley, travelled out 300 m. with man-hauled sledges and reached 6,500 ft. above sea-level at a point only a few miles from that reached by Sir Douglas Mawson and Sir Edgeworth David from McMurdo Sound on Sir Ernest Shackleton's expedition. The western party from the main base under Mr. F. H. Bickerton, with A. J. Hodgeman and Dr. L. A. Whetter, reached a point on the Antarctic circle in long. 138° E. on Christmas Day, travelling over the Plateau at a height of about 4,000 ft. An air tractor sledge started with this party but broke down after 10 miles.

Dr. Mawson, with Dr. X. Mertz and Lt. B. E. S. Ninnis, using dog sledges, set out for a long journey to the S. E. well inland of Madigan's party, and had very difficult ground to cover, including many rises to over 3,000 ft. with intermediate descents to near sea-level, where there were heavily crevassed glaciers. They had got out about 310 m. to nearly long. 152° E. when on Dec. 14 1912 Ninnis, with his sledge and dogs, broke through the snow covering of a crevasse of enormous depth and was instantly killed. Many essential parts of the equipment were lost with the sledge, and only six dogs in poor condition were left. From this point the homeward track was laid farther S. than the outward so as to avoid the great ups and downs, and the travellers pushed on in frequent bad weather on short rations supplemented by the flesh of the dogs. Both suffered severely from the insufficient and loathsome food, and Mertz collapsed on Jan. 6 1913 and died the following day, leaving Mawson alone 100 m. from the hut. After three days spent in cutting down the sledge and rearranging its load Mawson started on his lonely tramp, and after appalling difficulties, when nearly exhausted, he stumbled on a food depôt laid out by a search party 20 m. from the hut on Jan. 29 1913. It was Feb. 8 when he reached the hut and saw the "Aurora," but she was outward bound. A fresh relief party had come S. in the ship, and a second winter had to be spent in the hut, the isolation somewhat mitigated by wireless intercourse with Australia *via* Macquarie Island.

Capt. Davis, after landing the relief party and taking off all the others, waited for the return of Mawson as long as he dared, having in view the necessity of relieving Wild's party in Queen Mary Land, and the fact that every anchor on the ship had been lost in the fight with blizzards in Commonwealth Bay. He reached Wild's base just in time, got the party safely on board and returned to Hobart. From their base in long. 98° E. Wild's party had travelled W. to the Gaussberg in long. 89° E., and E. as far as long. 101° E., mapping the glaciers which descended from a plateau rising above 3,000 ft., as well as several islands off the coast. The "Aurora" returned to Commonwealth Bay on Dec. 13 1913, and after taking the base party on board made another voyage to Queen Mary Land and carried out valuable oceanographical work on the way back to Hobart.

W. Filchner (*1911–2*).—Lt. Wilhelm Filchner organized a German expedition to the Weddell Sea in 1911, and sailed from South Georgia in the "Deutschland" (Capt. Vahsel) on Dec. 11 in that year and entered the pack seven days later in lat. 61° S. The ship went S. approximately on the meridian of 30° W. and sighted land on Jan. 29 1912 in lat. 76° S.; about 2° S. and 8° W. of Bruce's Coats Land. The "Deutschland" proceeded along the new coast, named Luitpold Land, to lat. 77° 48′ S., long. 35° W. on Feb. 2 1912, where an indentation in the Barrier ice formed Vahsel Bay, whence the land rose to the S. and three nunataks were observed piercing the snow. Efforts to get farther S. on a westerly course failed, and on Feb. 6 it was decided to erect the winter hut on an iceberg which appeared to be firmly frozen to the Barrier and to offer an easy passage for dog-sledges to the land. All stores were transferred to the iceberg, when on Feb. 18 it suddenly began to move and ponies, dogs, stores and as much of the wood as could be saved were hurriedly reëmbarked. Two small depots of provisions were afterwards laid out on the Barrier ice as a base for land parties while the ship sought for winter quarters; but Capt. Vahsel feared the destruction of the vessel, and induced the leader to change his plans and return to South Georgia for the winter in order to try again next year. The return journey was commenced on March 4 1912, but four days later the ship was beset by young ice in lat. 74° S., long. 31° W., and remained fast, drifting with the winds and currents of the Weddell Sea all winter, on the whole westward and northward until the middle of August, when she was in lat. 66° S. and long. 44° W. Thereafter the drift was eastward and northward until she broke out of the pack in lat. 63° 40′ S. and long. 36° W. on Nov. 27 1912 and proceeded for home. The drift lasted for 264 days and no land was sighted, although a sledge journey was made westward to long. 45° W. in search of Morrell Land. Capt. Vahsel died during the drift, and the expedition broke up at South Georgia.

Shackleton's Weddell Sea Party (*1914–6*).—Sir Ernest Shackleton had completed his preparations for an attempt to cross the Antarctic regions from Weddell Sea to Ross Sea before the outbreak of the World War, and carried out his expedition at the direct order of the Admiralty, which declined his offer of the ships and men for war service. He left England on Aug. 8 1914 in the "Endurance" and sailed from South Georgia on Dec. 5, with the intention of landing in Vahsel Bay and proceeding thence to the South Pole after wintering on the land. The pack was entered in lat. 57° S. and the ship worked her way S. between long. 15° and 20° W. until on Jan. 11 1915 she sighted Coats Land, and followed new land named the Caird Coast to Luitpold Land. Here the "Endurance" was beset in the ice on Jan. 18 in lat. 76° 34′ S., long. 31° 30′ W. and the voyage was at an end. The "Endurance" drifted in the pack as the "Deutschland" had done three years before, and on a nearly parallel track, moving N. about 10° farther W. and at almost exactly the same rate in the same latitudes. The ice was however much heavier, and in the terrific pressures which occurred the "Endurance" was crushed on Oct. 27, when the expedition of 28 men with 49 dogs abandoned her and camped on the floe. This was in lat. 69° 5′ S., long. 51° 30′ W., and three weeks later the shattered wreck sank through the ice. The attempt to sledge over the ice westward towards the E. coast of Graham Land was unavailing, as the ship's boats could not be left behind and were too heavy to drag. The party therefore camped on the drifting floe, keeping up scientific observations and maintaining their health and spirits though in continual danger from the floes ridging up or cracking asunder. The drift went on until April 9 1916 when the floe, reduced to a triangle 100 yds. in the side, drifted into the open sea in lat. 62° S., long. 54° W., and the party had to take to their boats, after drifting 292 days in the ship and 165 on the bare ice, 457 days in all. North of lat. 66° S. the drift of the "Deutschland" had turned sharp to the E., but that of Sir Ernest Shackleton's floe continued in the main due N.; the difference may have been due to the opposite seasons or to other causes. The three boats safely reached Elephant I. in the South Shetlands, and a shelter was rigged up of two boats, where 22 of the party were left under the capable leadership of Mr. Frank Wild, while Shackleton and five companions set out in the third boat, the "James Caird," for the almost desperate attempt to reach South Georgia. The effort succeeded in great measure through the fine seamanship of Capt. Worsley, and the island was reached in 16 days on May 10 after a voyage of over 800 m., but on the side farthest from the whaling stations. After a four-days rest Shackleton, with two companions, had recovered sufficiently to cross the unknown snow-covered mountains, which had never

been climbed before, and a steamer was sent round for the others. Sir Ernest Shackleton made strenuous efforts to rescue the Elephant I. party first in a small steamer from South Georgia, then in a trawler from Montevideo, then in a little motor schooner from Punta Arenas, all of which were driven back by the ice floes near the South Shetlands, and finally in the "Yelcho," a tug from Punta Arenas, in which he reached the island on Aug. 30 1916 and brought back the whole party without a casualty.

Shackleton's Ross Sea Party (1914-7).—On the Ross Sea side the "Aurora," under command of Capt. Aeneas Mackintosh, brought an auxiliary expedition to lay out depots on the Barrier to facilitate the latter part of Shackleton's march from the Weddell Sea *via* the South Pole. The "Aurora" reached Cape Evans on Jan. 16 1915, and, while she remained there with the hope of wintering, Mackintosh and a sledge party laid out depots as far as lat. 80° S. by Feb. 20. This was a better record than in Scott's autumn journey of 1911; but it was midwinter before Mackintosh found the ice strong enough to permit of his return to Cape Evans. Early next summer he started S. again; was at the 80° depot on Jan. 6 1916 and with five companions reached Mt. Hope at the mouth of the Beardmore glacier in lat. 83° 30′ S. on Jan. 20 where he left a depot. The return journey was one of terrible hardship aggravated by scurvy, and the party narrowly escaped Scott's fate. Mr. Spencer Smith died, but the rest reached Hut Point on March 18 1916. In their anxiety to get back to the Cape Evans party, Mackintosh and Hayward attempted the journey on the sea-ice on May 8, but the ice was not strong enough and they were lost. It was July before the rest of the southern party reached Cape Evans.

On May 6 1915 the "Aurora," which had been frozen in and made fast by many cables to the shore at Cape Evans, was blown out to sea with all the ice and was held fast for 315 days, during which time she drifted northward through Ross Sea nearly in the same direction and at nearly the same rate as the "Endurance" was drifting at the same time in the Weddell Sea. She had been severely damaged by ice pressure; but Lt. J. R. Stenhouse, who was in command, rigged a new rudder, and when she was released on March 16 1916 in lat. 62° 27′ S., long. 157° 30′ E., he brought the disabled vessel safely to New Zealand. The ship was repaired by the New Zealand Government and dispatched under the command of Capt. J. King Davis with Sir Ernest Shackleton on board, and on Jan. 7 1917 she reached Cape Royds and rescued the seven survivors who had come safely through their two winters in spite of shortage of supplies, the winter stores not having all been landed when the ship was blown away. All of the 53 men who returned from the expeditions of the "Endurance" and "Aurora" served in the navy, army or air force during the World War, three being killed and five wounded.

Scientific Results.—The scientific results of the expeditions described above could not yet in 1921 be adequately summarized, for the war had retarded the investigation of the collections and the discussion of statistics. It would be impracticable to draw general conclusions as to the physical and biological conditions of the Antarctic regions until the researches of all the expeditions had been published in a comparable form.

All the inferences from earlier work required revision, but specialists of different expeditions had already committed themselves to views which could not be reconciled in the absence of full information from all explorers. This observation applies in particular to the general theory of the meteorology of the South Polar area, as expounded for the Gauss expedition by Prof. Meinardus and for Scott's last expedition by Dr. G. C. Simpson. The results of the Australian and German expeditions, which were for a great part of the time synchronous with those of Scott and Amundsen, required to be taken into consideration before a general theory of the atmospheric circulation within the Antarctic circle could be established. This is also the case as to geology, and the bearings of geological evidence on the probable nature and extent of the Antarctic continent, and the relations of that land mass to the other continents.

Priestley, *Antarctic Adventure, Scott's Northern Party* (1914); G. Taylor, *With Scott, the Silver Lining* (1916); Sir D. Mawson, *The Home of the Blizzard* (two vols. 1915); J. K. Davis, *With the "Aurora" in the Antarctic* (1920); Sir E. Shackleton, *South* (1919). (H. R. M.)

ANTHROPOLOGY.—The earlier article (*see* 2.108), discussing the problem of man's origin and the possibility of recovering fossils which would throw further light on early types of man, included the remarkable statement:—"It seems as if anthropology had in this direction reached the limits of its discoveries" (*see* 2.119). This prediction has fortunately been stultified almost every year since it was made, for later years have yielded an abundantly rich harvest of anthropological data and a clearer vision of their significance. In fact they have witnessed a profound revolution in every branch of the study of man. New and important information has been acquired concerning man's ancestry, and the factors that brought the Primates into existence and transformed one branch of the Order into the human family. Hitherto unknown types of fossil men have been found in the Mauer Sands near Heidelberg, at Piltdown in Sussex, at Talgai in Queensland, at Wadjak in Java and at Boskop in the Transvaal. So many examples of Neanderthal Man have been found at Le Moustier, La Chapelle-aux-Saints, La Quina, La Ferrassie, in Jersey and near Weimar, that we are now able to get a very clear idea of the appearance and distinctive features of the brutal species of man that preceded *Homo sapiens* in Europe. Much new information has been acquired of the different races of *Homo sapiens* that made their way into western Europe after *Homo neanderthalensis* disappeared from the scene; and the discovery of their paintings on the walls of caverns in southern France and in Spain and their plastic art has been an astounding revelation of the genius and skill no less than the artistic feeling of these earliest known members of the species to which we, and all men now living, belong.

The brilliant researches of French anthropologists have made it possible to classify the phases of culture of the so-called upper palaeolithic age and assign to each its distinctive features and its chronological sequence with reference to the other phases. Intensive studies of the older civilizations of Egypt, Elam, Sumer (and Babylonia, which succeeded it), Crete, the Aegean, Palestine, Syria and Asia Minor, have made it possible to understand the origin of civilization in a way that was undreamt of hitherto; and it is now possible confidently to sketch out the process whereby this common civilization was diffused into Europe, to Turkestan and India, to Siberia and China, to Indonesia and Oceania, until finally it crossed the Pacific to Central America and Peru. But perhaps the most profound change that was initiated in anthropology during the decade 1910-20 was the demolition of many of the dogmas which for half a century had paralyzed ethnological investigation and prevented those who were collecting the evidence from appreciating its real significance. This fundamental change of view had not in 1921 been generally accepted by ethnologists, but there were already then very obvious signs that many of them were preparing to repudiate the fashionable doctrine, which had been expressed in its most extreme form in the earlier article in this Encyclopaedia.

The Evolution of Man.—In spite of not infrequent attempts to disprove man's kinship with the apes, recent research in anatomy, embryology and comparative pathology, as well as the conclusive tests of blood-relationship, has definitely established the fact of man's close kinship with the anthropoid apes, and especially with the gorilla. But this fundamental conclusion is not in any sense invalidated by the clear recognition of the further fact that the ancestors of man and the gorilla respectively became differentiated the one from the other at least as early as the middle of the Miocene period. This does not mean that man's forebears assumed their human characteristics at the period mentioned, but rather that the ancestors of the gorillas and chimpanzees had begun to assume their distinctive specializations and to fall out of the race for intellectual supremacy which was eventually to be attained by the descendants of their unspecialized Miocene brothers. It is in the highest degree

probable that throughout the Miocene, man's ancestors were still simian. All we know of them is that certain fossil apes found by Dr. Pilgrim in the foothills of the Himalayas reveal curious little peculiarities of structure that serve to identify them in his opinion as members of the group of anthropoids from which the *Hominidae* were eventually derived—probably not until the latter part of the Pliocene (G. E. Pilgrim, "New Siwalik Primates," *Records of the Geological Survey of India*, xlv., 1915). But whether or not Dr. Pilgrim is justified in his claim that the newly discovered Miocene ape which he has called *Sivapithecus* is the ancestor of man or not, it is quite certain that in Miocene times the region of the Siwalik Hills was a great breeding-ground of anthropoid apes, and that the great variety of species and genera which were evolved there included the ancestors not only of the orangs, the chimpanzees and gorillas, but also of the human family. The ancestors of the chimpanzees and gorillas spread west with man's forerunners and reached not only Africa, where their descendants have survived until the present day, but also Europe where the fossilized remains of *Dryopithecus* are widespread. In the course of its wanderings between northern India and Africa human characteristics emerged in one of these simian forms.

The outstanding difference between the earliest member of the human family and his simian cousin was the fact that his brain had developed a little further than the ape's, so that he was able to learn to perform acts of a higher degree of skill not only with his hands but with his vocal muscles. He had acquired the power not merely of a fuller appreciation of the symbolism of sound, but also of arbitrarily imitating sounds and of creating a vocal symbolism whereby he could learn from his fellows and communicate his ideas to them. It was the enormously enhanced power of acquiring knowledge and profiting from the experience of his fellows that differentiated man from the apes; and the peculiar features of the endocranial casts of the fossils *Pithecanthropus* and *Eoanthropus* suggest that the acquisition of the power of speech may have been an essential part of the process of making a man from an ape.

If India has provided us with new light on the place and time of the separation of man's ancestors from the other apes, Egypt has revealed the origin of the anthropoids. It was in 1901 that Dr. C. W. Andrews, of the British Museum, discovered that the Egyptian Fayum was a veritable museum of hitherto unknown fossil ancestors of several mammalian Orders. His prediction that important monkeys would be found there has been fully realized by the discovery of the very primitive Catarhine *Parapithecus* and an anthropoid ape, *Propliopithecus* (M. Schlosser, "Beiträge zur Kenntniss der Oligozänen Landsäugetiere aus dem Fayum [Aegypten]," *Beiträge zur Pal. u. Geol. Österreich-Ungarns u. d. Orients*, Bd. xxiv., 1911). The discovery of a diminutive anthropoid as early as the beginning of the Oligocene period prepares us for the fact that it presents many signs of not distant kinship with the peculiar Eocene Tarsioidea, a Sub-Order of Prosimiae, one of whose members, the Spectral Tarsier, still survives to-day in the forests of Borneo, Java and certain other islands of the Malay Archipelago. For some years intensive studies have been made of the anatomy and embryology of this remarkable creature (see, for example, "the Discussion of the Zoölogical Position and Affinities of Tarsius," *Proc. Zoöl. Soc. London*, 1919, published Feb. 1920); and these investigations have shed a great deal of light upon the factors that brought the Primates into being and in one group of the Order initiated further changes, especially in the cultivation of stereoscopic vision and all that it entailed in the stimulation of brain-growth, which ultimately culminated in the emergence of human powers of foresight and discrimination (see *Presidential Address to the Anthropological Section of the British Association*, 1912).

Fossil Remains of Extinct Members of the Human Family.—The conclusion to which the study of man's ancestry had led investigators, that the brain led the way in the emergence of human characters, received a dramatic confirmation in 1912, when the late Mr. Charles Dawson and Dr. Smith Woodward announced that the former had discovered (in a patch of gravel alongside the path leading to Barkham Manor, the residence of Mr. Charles Kenward, near Piltdown in Sussex) fossilized fragments of the skull of a palaeolithic member of the human family quite unlike anything known hitherto (C. Dawson and A. Smith Woodward, "On the Discovery of a Palaeolithic Skull and Mandible in a Flint-bearing Gravel overlying the Wealden (Hastings Beds) at Piltdown, Fletching (Sussex)," *Quarterly Journal of the Geological Society*, vol. lxix. (1913) and vol. lxx. (1914); the best photographs of these highly significant specimens will be found in *A Guide to the Fossil Remains of Man in the Department of Geology and Palaeontology in the British Museum*, first issued in 1915). Sufficient of the cranium was recovered to restore the whole of the brain case; and it is important to remember that, although a lively altercation was provoked in 1913 as to the proper way of reconstructing the skull, there never was any real doubt as to the form of the brain case on the part of those who were studying the actual fossils, because these display the anatomical details which leave no room for any doubt on the points at issue. The interesting feature of the cast of the interior of the cranium is the demonstration it affords that this extremely primitive "Dawn Man," *Eoanthropus Dawsoni*, as Dr. Smith Woodward has called him, had a brain which fell definitely within the range (so far as size is concerned) of variation of modern men's brains. But it displayed some remarkable deficiencies, more especially in the singularly poor development of those frontal, parietal and temporal areas, the noteworthy expansion of which is the fundamental distinctive character of the human brain. Perhaps the most interesting feature of the endocranial cast of the Piltdown man is the remarkable localized overgrowth of that particular part of the brain (the posterior part of the superior temporal convolution) which in modern man is intimately associated with the appreciation of the acoustic symbolism of speech. As a somewhat analogous boss is found on the endocranial cast of *Pithecanthropus*, the fossilized remains of which were found nearly thirty years ago in Java by Dr. Eugen Dubois, it affords grounds for the view that the acquisition of speech may have been one of the essential elements in the transformation of an ape into a man.

It is of fundamental importance to realize that, in spite of its size, the endocranial cast of *Eoanthropus* reveals these indubitable traits of an extremely early phase in the attainment of human characters; and the brain was contained in a skull of a peculiarly distinctive type. For so simian is the form of the jaw that many anatomists and palaeontologists refuse to admit that it is human, and claim that a hitherto unknown chimpanzee expired at Piltdown in Pleistocene times on the same spot as *Eoanthropus* and that the former left its jaw and the latter its skull. This view is widely held, but chiefly by non-British anatomists (see, for example, M. Ramström, "Der Piltdown Fund," *Geol. Inst. of Upsala*, vol. xvi., 1919) who have never studied the actual fossils. Had they done so they would have realized that, in spite of its form, both the mandible itself and the teeth lodged in it display undoubted human characters. Moreover the cranium also reveals much more primitive features than is commonly supposed by those who have not seen and handled it. In fact there is no reason for withholding assent to the view that this remarkable cranium, which formerly lodged a brain of extremely primitive character, once formed part of the same individual whose jaw had not yet lost all the marks of the ape.

A vast amount of writing has accumulated since 1912 with reference to this remarkable skull, but most of this literature is irrelevant and misleading, as the authors have not seen the material about which they write and have no adequate realization of the true state of affairs.

As to the age of the Piltdown skull, precise information is lacking. It was found in an ancient river bed along with *rolled* teeth of Pliocene elephants and rhinoceros that had been washed out of some older geological formation, and unrolled teeth of early Pleistocene hippopotamus and beaver and the base of the antler of a red deer. From a consideration of all the evidence it

is reasonable to assume that the Piltdown man lived in the early Pleistocene period, and this inference is borne out by the crude implements of flint and elephant-bone found along with the skull. The crucial importance of *Eoanthropus* depends upon the fact that it is so obviously close to the main line of descent of modern man. Yet it reveals such astounding simian resemblances that many—perhaps the majority of—recent writers want to claim its jaw as a chimpanzee's. This in itself is a striking demonstration of the closeness of the affinity of primitive man and certain apes.

Although in 1921 it was nearly thirty years since Professor Eugen Dubois discovered at Trinil, on the banks of the Solo river in Java, the fossil which he regards as parts of one individual, *Pithecanthropus erectus*, his monograph on the subject had not been published. Nevertheless the stream of writings on this ape-man was still flowing unabated. In Boule's *Les Hommes Fossiles* (1921) the distinguished French palaeontologist still maintained that *Pithecanthropus* is not a member of the human family, but is an ape. Dubois himself maintains that it is neither a man nor an ape, but a creature really intermediate between them. But the endocranial cast of *Pithecanthropus* reveals the fact quite definitely and surely that as regards its size, shape and the relative proportion of parts, this so-called ape-man of Java comes within the range of the *Hominidae*. Moreover, as has already been mentioned, its endocranial cast exhibits a fullness of the postero-superior part of the temporal area which suggests the acquisition of the characteristically human power of speech. The question is still debated whether the thigh-bone found in the same bed as the skull-cap of *Pithecanthropus* really belonged to the same individual It is so obtrusively human that some authorities find a difficulty in associating it with the skull: but the balance of evidence is in favour of both being parts of one individual, the most primitive and the earliest known member of the human family, aberrant both in physical type and habitat. Controversy was still proceeding in 1921 as to the age of the *Pithecanthropus* remains, and new evidence provided by the Selenka expedition has been used to strengthen the hands of those who object to the claim of Dubois that the remains belong to the Upper Pliocene and maintain that these earliest known representatives of the human family are to be referred definitely to the commencement of the Pleistocene period (Selenka and Blanckenhorn, "Die Pithecanthropus-Schichten auf Java," *Geologische und palaeontologische Ergebnisse der Trinil-Expedition*, Leipzig, 1911).

In 1905 the remains of *Pithecanthropus* represented the only known member of the family *Hominidae* which did not belong to the genus *Homo*. Since then, however, the remains of other forms have been revealed that surely deserve generic distinction. In 1907 a human lower jaw was found in the base of the Mauer Sands near Heidelberg, which was described by Schoetensack as a hitherto unknown member of the human family which he called *Homo heidelbergensis*. But its age and peculiar features remove it so far from all the members of the genus *Homo* that it is more in accordance with the proper perspective to follow Bonarelli who has created for its reception the genus *Palaeoanthropus*. It is extremely massive and is unlike any other human jaw, not merely by reason of its size but also in the ape-like recession of its chin.

Neanderthal Man.—The fossilized remains of part of a cranium and some long bones found in 1856 by some workmen in the Feldhofer Grotto in the Neanderthal Valley (between Elberfeld and Düsseldorf in Rhenish Prussia) are now generally admitted to represent a species of the genus *Homo* that is definitely differentiated from the species *sapiens*, to which all the living races of man belong. This extinct species is known as *H. neanderthalensis*, a name first suggested in 1864 by Prof. King of Galway. In 1848 a fossil skull was found at Gibraltar by Lt. Flint, but no attention was devoted to it until Busk described it in 1864; and it is now commonly supposed to be a female of the Neanderthal species; but Sera (*Soc. romana di Antrop*, xv. 1909) considers it to be more primitive and earlier than the true Neanderthal people. Other examples of the Neanderthal species have been found in the grotto of Spy (Belgium) in 1886, at Krapina (Croatia) in 1899, at La Chapelle-aux-Saints (La Corrèze, France) in 1908, Le Moustier in the Dordogne (1909) and in the same year at La Ferrassie in the same region. Another skull was found in the same region in 1910, and in 1911 yet another at La Quina (Charente). To this remarkable series of skeletons found in France, which give us so complete a picture of the distinctive features of this brutal extinct species of our genus, is to be added fragments of two jaws found in 1914 at Ehringsdorf near Weimar in Germany (see Hans Virchow, *Die menschlichen Skeletreste aus dem Kämpfischen Bruch im Travertin von Ehringsdorf bei Weimar*, Jena, 1920). The vast literature that has accumulated with reference to the other examples of *Homo neanderthalensis* will be found summarized in M. Boule's *Les Hommes Fossiles* (Paris, 1921) as well as in H. F. Osborn's *Men of the Old Stone Age* (New York, 1915) and W. J. Sollas's *Ancient Hunters and their Modern Representatives* (London, 2nd ed. 1914).

Neanderthal man is now revealed as an uncouth race with an enormous flattened head, very prominent eye-brow ridges and a coarse face. The trunk is short and thick, the robust limbs are short and thick-set: the broad and stooping shoulders lead by a curve to the forwardly projected head set on an abnormally thick neck. The hands are large and coarse and lack the delicate play between thumb and fingers which is found in *Homo sapiens*. The large brain is singularly defective in the frontal region. It is clear that Neanderthal man's limbs and brain were incapable of performing those delicately skilled movements that are the distinct prerogative of *H. sapiens* and the chief means whereby the latter has learned by experiment to understand the world around him, and to acquire the high powers of discrimination that enabled him to compete successfully with the brutal strength of the Neanderthal species.

The Neanderthal race of men, with their distinctive Mousterian culture, suddenly disappeared from Europe, and were replaced by immigrants belonging to our own species, who brought with them to Europe the germs of the phase of culture known as Aurignacian. These newcomers were members of the Cro-Magnon race, a very tall people with large dolichocephalic skulls and relatively broad face. They probably entered Europe from the S., because their settlements are found chiefly near the Mediterranean coastline, in northern Africa, Sicily, Italy, southern France and Spain. The coming of this superior race of highly intelligent men is revealed also by the sudden improvement in the technique of the flint-work and the appearance, especially in the caves of southern France, of mural paintings revealing new powers of artistic observation and skill in depicting the animals which these people hunted. There is revealed for the first time the genius and the aesthetic feeling of members of our own race. At a later period the members of another race (also dolichocephalic, but with much narrower and more harmonic face than the Cro-Magnon people) began to make their way into Europe from the East, probably by way of Poland and Moravia, Hungary and Bavaria, thence into France. These people are often known as the Brünn race and their culture as Solutrian. The skeletons are found deeply imbedded in loess along with the bones of the woolly mammoth, woolly rhinoceros, giant deer, reindeer, etc. Their culture is distinguished by the wonderful skill in flaking flint implements. Although it lasted only a short time in Europe and never extended as far as Spain or the Mediterranean area, this method of stone-working spread far and wide, to Egypt, Australia and America, and in the latter two countries persisted until the present time.

After the Solutrian came the Magdalenian phase of culture, which marked the culmination of the skill and achievement of man before agriculture. This new development was not derived from the Solutrian art, but was brought into Europe and replaced the latter. It lacked the superb skill of the Solutrian flint-workers, but was characterized by a high degree of ability in painting and sculpture.

For information concerning the culture of the Magdalenian epoch in France and Spain see Osborn's *Men of the Old Stone Age*; also the

books by Déchelette, *Manuel d'archéologie préhistorique, celtique et gallo-romaine*, Paris, 1910–13 and Sollas, *Ancient Hunters and Their Modern Representatives.*

The Magdalenian phase of culture in western Europe was succeeded by the Neolithic, a momentous event, which was heralded by the arrival in different parts of Europe of a variety of races:—(*a*) an advance wave of the Mediterranean race which was soon to introduce the distinctive elements of the Neolithic culture, but at first introduced the Azilian-Tardenoisian industry into Spain and France; (*b*) another offshoot of the Mediterranean race that made its way to Ofnet in Eastern Bavaria; (*c*) a race possibly of Nordic affinities that appeared on the coasts of the Baltic, but is known only by the Maglemose industry; and (*d*) a broad-headed advance guard of the so-called Alpine or Armenoid race (distinguished as Furfooz-Grenelle) found along with the dolichocephalic people at Ofnet and also in Belgium.

The coming of the Neolithic people into western Europe marks the advent there of people who brought the rudiments of the great world civilization that was being built up in the Ancient East. For the cultivation of barley and wheat, the making of pottery, the weaving of linen and several other distinctive features of the Neolithic phase of culture are clearly instances of customs which had their origin in Egypt or its neighbourhood at a time when western Europe was still in the so-called "Upper Palaeolithic" phase. Towards the end of the Neolithic phase in the W., when megalithic monuments make their appearance as crude imitation of the stonework of the Pyramid Age in Egypt ("The Evolution of the Rock-Cut Tomb and the Dolmen," *Essays and Studies presented to William Ridgeway*, 1913), we get even more definite indications of the source and date of the cultural inspiration to build such peculiar and distinctive structures; and the close identity of their geographical distribution with those of the ancient exploitation of flint, gold, copper, tin, pearls, jet, amber and purple indicates clearly enough the motives that attracted the culture-bearers to certain localities and made them *foci* of new developments of culture (W. J. Perry). It is important to remember that in the home of their invention the working of gold and copper preceded the building of stone monuments by some centuries; but as prospectors searched for gold and copper ores they invaded territories and obtained these materials from them long before the metals themselves were worked or used locally, *i.e.* while the latter still remained in the stone phase of culture. These are very cogent reasons for the belief that the working of copper first began in Upper Egypt or Nubia (Reisner, quoted by Elliot Smith, *The Ancient Egyptians*, chap. 1; see also *Man*, Feb. 1916, p. 26) and from there spread to Palestine and Syria, to Elam and Asia Minor, Cyprus and the Aegean. It is probable that the making of bronze was first devised early in the third millennium in the neighbourhood of the south-eastern corner of the Caspian, perhaps near Meshed, and from there the practice spread W. and S., and later E., until not only western Asia and Europe passed into a Bronze Age, but also eastern Asia and Central and S. America.

The Talgai and Wadjak Skulls.—At the meeting of the British Association in Sydney in 1914 Profs. J. T. Wilson and T. W. Edgeworth David exhibited the fossilized skull of a boy of about fifteen years of age, which had been picked up thirty years before in Queensland. A full account of this skull was published in 1918 (Stewart Arthur Smith, "The Fossil Human Skull found at Talgai, Queensland," *Philosophical Transactions of the Royal Society*, B, vol. ccviii.). The interest of this earliest Australian skull lies in the fact that it conforms so closely to the type of the existing aboriginal Australian, its only peculiarity being the exceptional size of the palate and teeth, and especially of the large and salient canine teeth. The discovery of fossilized dog's teeth in the cave breccias of New South Wales and Victoria go to prove that early man accompanied by his dogs must have ferried across Wallace's line to make his way into New Guinea and Australia.

The publication of the account of this proto-Australian skull stimulated Prof. Eugen Dubois to announce the information that thirty years earlier he had found fossilized remains of members of the same race at Wadjak in Java ("De proto-Australische fossiele Mensch van Wadjak, Java," *Koninklijke Akademie van Wetenschappen te Amsterdam*, Deel, xxix., May 29 1920).

Boskop Skull.—About the same time that the discovery of the Talgai skull was announced in Australia the discovery was recorded of a very different type of fossilized skull from Boskop in the Transvaal (S. H. Haughton, "Preliminary Note on the Ancient Skull Remains from the Transvaal," *Transactions of the Royal Society of South Africa*, vol. vi., 1917). The fossils consist of part of the brain case and jaw of a type of man differing profoundly from the earliest known inhabitants of S. Africa, the Bushman and the Hottentot. They represent the remains of a variety of *Homo sapiens* in some respects akin to the Cro-Magnon race, the earliest type of *Homo sapiens* known in Europe.

Oldoway Skull.—In 1914 also the fossilized remains of a human skeleton were found in Central Africa (H. Reck, "Erste vorläufige Mitteilung über den Fund eines fossilen Menschenskeletts aus Zentralafrica," *Sitzungsberichte der Gesellschaft naturforschender Freunde zu Berlin*, 1914), but adequate information concerning this discovery is still lacking.

Early Man in America.—Although it is certain that at a relatively early period in the history of *Homo sapiens* there must have been an immigration (by the Bering Strait route into N.W. America) of people sprung mainly from the proto-Mongolian stock, living E. of the head-waters of the Yenisei river, no remains of really early man in America have yet been discovered. The mere finding of implements of Palaeolithic types proves little, because the making of such implements has survived in the East, and the art may have been carried to America within relatively recent times. Up to 1921, the most recent discovery of human remains supposed to be early was made at Vero in Florida in 1916, but the geological evidence showed that the fossilization had occurred in post-Pleistocene times. There is, however, still great uncertainty as to the age of these remains, which do not differ in type from many modern American Indians.

The whole problem of early man in America has been explored in a severely critical spirit by Dr. Ales Hrdlicka, who gives a full bibliography ("Skeletal Remains suggesting or attributed to Early Man in N. America," *Smithsonian Institution, Bureau of American Ethnology, Bull.* 33, Washington, 1907; "Early Man in S. America," *ibid.*, 1912; and "Recent Discoveries attributed to Early Man in America," *ibid.*, 1918).

It is probable that the substratum of the early population of America consisted of a colony of a proto-Mongolian race mixed perhaps to some extent with proto-Armenoid elements in the original Siberian homeland. In later ages, more especially between about 300 B.C. and 1000 A.D., this population in America has been very considerably diluted—more especially on the Pacific coast—by a steady percolation of a variety of alien elements into the N.W. coast from Asia and into Central and South America from Polynesia and Micronesia in numbers sufficient materially to affect the physical type of the people of the western littoral and differentiate them from the eastern people.

For the evidence in support of this (but with a different interpretation) see Clark Wissler, *The American Indian* (New York, 1917). Dr. Wissler's book is also an invaluable summary of the present state of our knowledge of the geographical distribution of the arts and crafts of America, and a striking demonstration of the fact that the arts of agriculture, pottery, weaving, stone-working, metallurgy, etc., were diffused abroad in America from one centre somewhere in the region of Honduras. But he stoutly denies the conclusion (which emerges so clearly from the evidence he presents) that the elements of this exotic culture were planted in Central America by small groups of immigrants who had crossed the Pacific Ocean via Polynesia from Cambodia and Indonesia.

Classification of Existing Races.—Between 1910–20 it became increasingly clear that the generally adopted classification of mankind and of early culture was unsatisfactory, and not in full accordance with the facts that are now available. The introduction of the terms "Palaeolithic" and "Neolithic" by Sir

John Lubbock (afterwards Lord Avebury) served a useful purpose for a time in discriminating between the early and the later methods of flint-working before the discovery of bronze. But it is now known that the great break in the technique of stone-working did not occur at the transition from the Palaeolithic to the Neolithic phase, but when the so-called "Lower Palaeolithic" gave place to the so-called "Upper Palaeolithic."

The vast significance of this great revolution in man's history (at any rate in western Europe) is emphasized by the fact that it coincided with the final disappearance of the species *H. neanderthalensis* and the coming of the members of the species to which we ourselves (and all existing members of the human family) belong, *i.e. H. sapiens*. The replacement of the degraded type of mankind with his crude Mousterian culture and the coming of *H. sapiens* with his greater skill and artistic aptitude is surely the most significant revolution in the whole of man's history. To discriminate between these two phases of culture, Elliot Smith has suggested the terms, "palaeanthropic" and "neoanthropic" to apply respectively to the extinct species and their works and *H. sapiens* and his achievements ("Primitive Man," *Proceedings of the British Academy*, 1917).

All the races of man that exist at present belong to the species *sapiens*, but they differ profoundly in type and in the probable dates of their differentiation the one from the other. The most primitive race of all is the aboriginal Australian, who represents the survival of the earliest phase of *H. sapiens* with relatively slight change. After he separated from the rest of mankind he found a home in India, where he formed the substratum of the aboriginal people called pre-Dravidian. The rest of this race wandered E. until they reached Australia, small remnants remaining in some of the Indonesian Is. as abiding witnesses of the ancient migration. Probably at a much later period the Negro and Negritto became differentiated from the rest of mankind and found their area of characterization in tropical Africa, from which place in later times negroid peoples drifted along the whole southern littoral of Asia to Indonesia and Melanesia. It is probable that the Bushmen and Hottentot races represent early differentiations from the Negro stock. These two races, Australian and Negro, retain the black colour of skin which originally was probably common to all mankind and his nearest relatives, the gorilla and chimpanzee. After the Australian and Negro had been differentiated the rest of the human family attained a higher plane of development associated with a bleaching of the skin, a refinement of the features and a further growth and specialization of the brain. This pale-faced stock became broken up during the glacial period into four main stocks which became isolated the one from the other. Probably the earliest to wander off and become segregated—possibly in the region of the Yellow river—was the proto-Mongolian group which in course of time became specialized in structure as the Mongolian race. The next group probably found its area of characterization in N.E. Africa where it assumed the less specialized, *i.e.* relatively primitive, features that distinguish the Brown or Mediterranean race. Two other groups became isolated in the N.—one, probably in Turkestan, assumed brachycephalic traits and developed into the so-called Alpine or Armenoid race; the other, somewhere to the N.W., retained its primitive dolichocephaly but developed the distinctively blond traits that are the obtrusive characteristic of the Nordic race. Within each of the areas of characterization groups became isolated and differentiated in greater or less degree the one from the other. Moreover at the end of the glacial period, when the great ice-barriers disappeared there was extensive intermingling not merely of the formerly isolated groups of the same race, but also of different races. In Siberia especially there was a complex intermixture of Armenoid, Mongolian and Nordic peoples; and in western Asia and the Mediterranean littoral a variety of blends of Brown and Armenoid peoples. It was probably after a certain amount of such intermixture had occurred near the head-waters of the Yenisei that an essentially proto-Mongolian people moved E. and crossed into America as the first inhabitants of the New World.

The whole racial problem was in 1921 still in process of reconsideration. The best collection of facts relating to the subject will be found in the new edition of Keane's *Man, Past and Present*, edited by Quiggin and Haddon (Cambridge, 1920), but the headings of the chapters preserve the fallacies of the effete system of classification that is now being discarded.

Only the most inveterate prejudice can blind one to the fact that the widespread movement of small groups of people in Polynesia (the chief ingredients in whose constitution were elements of the Brown and Armenoid races) served to link up America with the Old World, and to provide the means whereby the elements of the early civilization of south-eastern Asia were introduced into Central America and Peru. No ethnologist doubts for a moment that the early mariners reached Easter I., because the island is peopled, and the language and the culture of the islanders afford proof of the fact that they came from the West. But it must be apparent that for every ship that chanced to strike that microscopic islet in eastern Polynesia there must have been hundreds, if not thousands, that missed it and were swept on to the coast of America. The whole culture of this Pacific littoral affords corroborative evidence of the fact that these early mariners did plant in Central America and Peru the beliefs and customs which we know them to have had. Mr. Charles Hedley claims (*Man*, Jan. 1917, p. 12) that the peoples of Oceania obtained from America the coconut and the sweet-potato as the result of such intercourse. The recent discovery (Chinnery) of the use of tobacco in the central highlands of New Guinea raises the question whether America learned the use of tobacco from Papua or the reverse. The very primitive and peculiar methods of smoking tobacco that Lt. Chinnery discovered in New Guinea suggest that if introduced from the East it must have occurred at a relatively remote period.

The Diffusion of Culture.—For half a century ethnology has been suffering from a grave reaction which it is only now beginning to overcome. Thus in the earlier article it was stated (*see* 2.119):—

"Anthropological researches undertaken all over the globe have shown the necessity of abandoning the old theory that a similarity of customs and superstitions, of arts and crafts, justifies the assumption of a remote relationship, if not an identity of origin, between races. It is now certain that there has ever been an inherent tendency in man, allowing for difference of climate and material surroundings, to develop culture by the same stages and in the same way. American man, for example, need not necessarily owe the minutest portion of his mental, religious, social or industrial development to remote contact with Asia or Europe, though he were proved to possess identical usages. An example in point is that of pyramid-building. No ethnical relationship can ever have existed between the Aztecs and the Egyptians; yet each race developed the idea of the pyramid tomb through that psychological similarity which is as much a characteristic of the species man as is his physique."

This once authoritative statement is cited at length to call attention to the actual teaching in ethnology which went far to sterilize half a century's intensive investigation; and as the present tendency is to sweep away all such sophistry and introduce into ethnology the real scientific method, it will be useful to examine the claims of the system which has to be got rid of.

Let us take the above five sentences as quoted seriatim. As it stands the first sentence would be altogether satisfactory if it really meant that ethnology utterly and totally disclaimed the view that similarity of customs implied racial kinship. The fact that a Japanese makes a steam-engine does not transform him into an Englishman! But as the second sentence shows, the ethnologists were confusing race and culture. The Japanese engineer who builds the steam-engine does not do so because there is "an inherent tendency in man to develop culture in the same way": the fact that the making of a steam-engine does not transform him into an Englishman does not preclude the recognition of the debt he owes directly or indirectly to Englishmen for the idea and for the methods of putting it into practice. Instead of it being "now certain" that there is "an inherent tendency in man" (in other words what the psychologist calls an instinct) to build steam-engines or pyramids, both the facts of history and the principles of psychology teach us that there

is no such specialized instinct. With reference to the protest that American man did not borrow mental, religious, social and industrial ideas from Asia, no one has provided more cogent illustrations of the fact that he did do so than the author of the disclaimer himself (see, for example, "On the Diffusion of Mythical Beliefs as Evidence in the History of Culture," *Report British Association*, 1894, p. 774; "On the Game of Patolli," *Journal Anthropological Institute*, vol. viii., 1879, p. 128). The series of step-pyramids that are scattered from Mesopotamia to Ceylon, to Cambodia and Java, to Japan and Shantung, to Tahiti and the Marquesas, to Peru and Mexico afford so striking a demonstration, not only of the spread of a very definite and peculiar phase of culture, but also of the route of the diffusion that many of the reactionary school in ethnology have felt it incumbent on them to get rid of evidence that was so awkward and obtrusive.

It was formerly claimed in effect that man had a pyramid-building instinct, which presumably was kept in check by the vast majority of mankind, but burst its bounds in a chronological sequence among the peoples scattered along the coasts from Egypt to Central America. The more fully the details of these pyramids are studied the more complete is the demonstration of their derivation one from the other as the stream of culture moved from West to East. In Ceylon at Polonnaruwa we find pyramids of Mesopotamian design but built of stone like those of the Egyptians. The less ornate Khmer pyramids, such as Ka-Keo and Ba-Kong, of Cambodia, reproduce the Sinhalese models with singular accuracy: and then pyramids of the same type appear in western Peru and Equador, Central America and Mexico, the Mississippi Valley and the south-eastern region of the United States, the transference of the incentive across the Pacific having been effected probably between the third and the tenth centuries A.D.

The acceptance of ideas concerning the possibility of spontaneous generation—with curious lack of knowledge and logic the ethnologists called it "evolution"—of similar ideas and customs among widely distant peoples was paralyzing the study of ethnology and removing it farther and farther from the stimulating influence of serious discussion and honest observation. Dr. W. H. R. Rivers was mainly responsible for leading ethnology out of this morass. In his presidential address to the Anthropological Section of the British Association in 1911 he exposed the fallacies of the popular ethnological doctrine and insisted on the importance of the diffusion of culture. One of the fallacies that had led ethnologists astray and facilitated the acceptance of the weird speculation of spontaneous generation of culture was the belief that useful arts could not be lost. One finds this view expressed in the earlier article (*see* 2.117):—

"Had the Australians or New Zealanders, for instance, ever possessed the potter's art, they could hardly have forgotten it."

By demonstrating the fallacy of this argument and showing that even so vital an art as boat-building could be lost by an island people, Dr. Rivers (*Report British Association*, 1912, p. 598; also *Festsscrift Tillägnad Edvard Westermarck*, Helsingfors, 1912, p. 109) removed the only serious obstacle in the way of the acceptance of the truth of the diffusion of knowledge in the way we know it to have been spread abroad in historical times.

From a detailed study of the technique of embalming Elliot Smith became convinced that the evidence provided by mummies from the islands in Torres Strait was so conclusive a proof of the influence of Egypt as to leave no possibility of doubt as to the certainty of the spread of culture from Egypt to New Guinea and Australia; and as the result of an examination of methods of mummification in various parts of the world he put forward a theory of *The Migration of Early Culture* (Manchester, 1915), in which the evidence provided by the geographical distribution of megalithic monuments, sun-worship, ear-piercing, tattooing, couvade, artificial deformation of the head, the use of the swastika, etc., was used to corroborate the reality of the diffusion of the ingredients of early civilization. If, as this theory claimed, the spread of culture took place in large measure by sea ("Ancient Mariners," *Journal of the Manchester Geographical Society*, 1917), the Indonesian archipelago ought to preserve some evidence of the movement by which the custom of building stone monuments reached Oceania from the West. This evidence was revealed by Mr. W. J. Perry (*The Megalithic Culture of Indonesia*, Manchester, 1918), who rendered an even greater service by explaining the motives of the wandering peoples who were mainly responsible for distributing abroad throughout the world the germs of civilization. Men prospecting for gold, copper, silver, tin and other metals, or for flint, turquoise, lapis lazuli, amber or jet, or divers searching for pearls or pearl-shell were the means of planting the elements of culture in outlying places in the world and making them foci of civilization ("The Relationship of the Geographical Distribution of Megalithic Monuments and Ancient Mines," *Mem. and Proc. Manchester Lit. and Phil. Soc.*, 1915; "The Geographical Distribution of Terraced Cultivation and Irrigation," *ibid.* 1916; "An Ethnological Study of Warfare," *ibid.* 1917; "War and Civilization," *Bull. John Rylands Library*, vol. iv., 1918).

Since Perry put forward this illuminating suggestion its truth has been repeatedly confirmed by investigations in the British Is., in the Caucasus, in Hyderabad, in Siberia, in eastern Asia, in New Guinea and Oceania, and especially in America. Working out the details of the geographical distribution of the different ingredients of civilization one is now able to reconstruct the past history of the beginning of culture and its diffusion throughout the world. We now realize that the incentive that spurred men on to build up the artificial structure of civilization was primarily the instinct of self-preservation. The realization of the dangers to life impelled men to seek for materials which they believed to be life-giving or death-averting. This was the original value attached to pearls and gold, to incense and jade, and to most of the things which the earliest members of our species sought for in the belief that no adventure was too hazardous and no danger or difficulty too great if by overcoming it they could secure the elixir of life (Elliot Smith, *The Evolution of the Dragon*, Manchester, 1919).

The Beginning of Agriculture.—If one single event more than another can be regarded as the foundation of civilization it is surely the invention of agriculture. Much speculation has been made as to where and how this crucial event was brought about; but the breeding experiments of such investigators as Prof. Biffen of Cambridge and the late Mr. Aaronsohn (see Coulter, *Fundamentals of Plant Breeding*, 1914, p. 192) dispose once for all of the popular view that primitive man more than sixty centuries ago produced the barley and wheat, which has been the staple foods of a large section of mankind since then, by an elaborate and long-continued process of experimental breeding. Having disposed of this anachronism, one is in a better position to appreciate the cogency and conclusiveness of the claim set up recently by Prof. Thomas Cherry of Melbourne ("The Discovery of Agriculture," *Proceedings of the Australian Association for the Advancement of Science*, 1921), that the Nile valley was the place where barley was found growing in a natural state, and that agriculture associated with basin irrigation was invented simply by imitating the natural conditions which the proto-Egyptians had constantly before their eyes. Dr. Cherry has pointed out that in Egypt alone the climatic and seasonal conditions are favourable for the natural growth of barley; and we know that it was the staple diet of the earliest Egyptians (G. Elliot Smith, *The Ancient Egyptians*, 1911, p. 41). The climatic conditions in Mesopotamia, Syria, and Asia Minor are such that the cultivation of barley became possible there only when men applied the lessons of artificial irrigation which they had acquired in Egypt. Dr. Cherry believes that wheat must have grown naturally on some of the smaller Aegean islands—he mentioned Melos and Naxos—and was first cultivated centuries after barley and by men who had learned the art of agriculture directly or indirectly from Egypt. But before the close of the fourth millennium the Egyptian technique of agriculture and irrigation had been adopted in Sumer and Crete and probably also in Syria and Asia Minor. Soon afterwards it was to spread N. and E. to Turkestan and Baluchistan

and in the W. to Europe, as one of the distinctive features of the Neolithic Age there.

The effect of the discovery of a means of securing a certain food supply capable of being stored for use in the lean periods of the year not only led, for the first time in the world's history, to a settled community and a steady increase in population within the settlement, but in addition it gave men leisure to think of other things than the mere struggle for existence. It is no mere chance circumstance that the invention of agriculture is intimately related to the development of the potter's art, to the building of more pretentious houses, to the weaving of linen and the domestication of milk-giving cattle. But it also provided the predisposing circumstances that compelled the organization of labour and the assumption of control of his fellow men by a leader who became a king, and brought about the curious result that the chief function of this earliest ruler was to be the irrigation engineer to the community, as we know to have been the case both in Egypt and Sumer. As this settled community in the Nile valley increased in numbers the necessity was forced upon it of making more ample provision for disposing of its dead; and out of the circumstances that attended these events there came into existence the arts of the embalmer, the carpenter and the stonemason. Architecture had its birth in the proto-Egyptian necropolis. Ship-building also was invented in close association with this train of events: and the first great maritime expeditions of which any hint has survived had for their object the obtaining of materials needed by the embalmer and the tomb-builder. Probably in the fourth millennium sea-going ships were already trafficking to Syria, Asia Minor and Crete, to southern Arabia and E. Africa (Elliot Smith, "Ancient Mariners," *Journal of the Manchester Geographical Society*, 1917).

The Beginning of Civilization.—After many years of fluctuating diversities of opinion it is now widely admitted that there is a very close genetic relationship between the earliest civilizations of Egypt and Babylonia. The identity of their burial customs, their methods of agriculture and irrigation, the use of bricks, cylinder seals and mace-heads, the use of copper and painted pottery, the weaving of linen and the choice and methods of preparing cosmetics, and above all their beliefs and religious practices—these and scores of other customs reveal the fact that the cultures of the earliest peoples of Egypt, Sumer and Elam were derived from a common source. The recent incident that compelled scholars frankly to admit the reality of the cultural link between Egypt and Babylonia in very early times was the acquisition by the Louvre of a predynastic flint-knife with a handle carved from the tooth of a hippopotamus which is said to have come from Gebel el-Arak near Nag'Hamadi in Upper Egypt (Bénédite, "Le couteau de Gebel el-Arak," *Fondation Eugène Piot, Mon. et Mém.*, xxii., i., 1916). The design engraved on the handle is claimed to be very un-Egyptian and to afford certain evidence of cultural contact with Sumer. But many scholars now claim that Egypt obtained the elements of her civilization from Sumer (see, for example, Prof. S. Langdon, "Early Chronology of Sumer and Egypt," *Nature*, May 5 1921, p. 315). In support of this contention Prof. Langdon claims that "recently discovered dynastic tablets establish the date of the earliest kingdoms of Mesopotamia as early as 5000 B.C."; whereas he attempts to fix the beginning of the first Egyptian dynasty by comparing the methods of year-dating of the famous Naram-Sin (2795–2739 B.C.) with those of Egypt, arguing that Naram-Sin borrowed his system of year-dating from Egypt and was contemporaneous with the last two kings of the second Egyptian dynasty. He claims to have confirmed the date *circa* 3200 B.C. for Menes. But a wholly unexpected revision of Egyptian dating has come from the German school of archaeology which was responsible for the minimal date 3200 B.C. which Prof. Langdon claims to have established by independent evidence.

Prof. L. Borchardt has recently set forth at length a series of arguments, mainly based on astronomical data, to prove that the first Egyptian dynasty began in 4186 B.C. and that the sixth dynasty lasted from 2920 to 2720 B.C. (*Die Annalen und die Festlegung des Alten Reiches der Ägyptischen Geschichte*, Berlin, 1919). This new estimate, even if it should prove to be true, would not necessarily be fatal to Langdon's claims. But there are reasons of other kinds that demonstrate the derivation of Sumerian and Elamite culture from Egypt.

If it can be shown that Egypt was the home of the invention of agriculture and irrigation, of the working of gold and copper, of the weaving of linen and the making of bricks, of the building of sea-going ships and the use of incense it necessarily follows that Sumer and Elam must have acquired these practices from Egypt, especially as Prof. Langdon rightly claims that the spread of culture took place mainly by sea-routes. As neither the Sumerians nor the Elamites are known to have built sea-going ships nor to have had any motives for doing so, one naturally assumes that the Egyptians (as the builders of the earliest known sea-going ships) took the initiative in opening up the communication by sea with the Persian Gulf, as we know they did with Crete and the coasts of Palestine, Syria and the Red Sea. But the facts brought to light by the French excavations in Elam seem to prove quite conclusively that the predynastic civilization of Egypt was planted there, probably by miners working the copper ore.

Perhaps the most valuable evidence bearing on the early inter-relationships of Egypt, Elam and Sumer and the wider spread of their cultural influence is afforded by the important study of early painted pottery, which M. Edmond Pottier contributed to the valuable series of reports of M. de Morgan's Délégation en Perse ("Étude Historique et Chronologique sur les Vases Peints de l'Acropole de Suse," *Mémoires de la Délégation en Perse*, Tome XIII. "Recherches Archéologiques," 5ième Série, 1912, p. 27). According to him Susian ceramic ware is revealed as the product of a very primitive civilization; but in addition it recalls (or perhaps it would be more correct to say, reveals the germ of) certain highly perfected industries such as that of the Greeks. It is, in fact, an amazing mixture of inexperience and skill—the sort of result one might expect to find when an industry which has been developed elsewhere is suddenly transplanted to a new country, and work requiring special skill is unavoidably entrusted to the incompetent hands of local artisans. The Susian workmanship in fact displays clearly the fact of the derivation of the ceramic craft from elsewhere.

In the lowermost level in which there is any evidence of human occupation at Susa, pottery was found in association with copper and stone weapons. This suggests, according to Pottier (p. 60), that the pottery is Eneolithic and that the first colonization of Susa took place in the Eneolithic epoch. For in this lowest level the evidence of the arts and crafts indicates that a fully-developed civilization was present from the beginning of the Susian record preserved for us to study. Linen, for example, was found along with the weapons—an association with copper and painted pottery which further strengthens the proof of the Egyptian origin of the imported Susian civilization. Necklaces of lapis lazuli and turquoise afford evidence, according to Pottier (p. 61), of foreign relations. They suggest, in fact, the possibility of connexions with the regions around the southern end of the Caspian (13 and 14) where these stones are found and were worked in very early times.

Discussing the date of these earliest Susian remains M. Pottier (p. 65) thinks that they are slightly earlier than any of the known Sumerian objects: but he is not inclined to accord them an age many centuries earlier than the time of Ur Nina of Lagash (2800 B.C.). It seems quite clear that there are no valid reasons for attributing to any Elamite or Sumerian remains a date earlier, if indeed as early, as that of the First Egyptian Dynasty. Now the proto-Egyptians had been working copper, making linen and painting pottery, for many centuries before this earliest possible date for the commencement of Elamite and Sumerian civilization. Hence, as undoubtedly borrowing did occur, it is clear that Elam and Sumer acquired the germs of their civilization directly or indirectly from Egypt, or from the same source as Egypt.

M. Pottier does not go so far as to make this claim, but he submits all the evidence that makes its adoption unavoidable:—"En examinant les monuments égyptiens de l'âge préhistorique et des premières dynasties, tout le monde sera frappé des traits de ressemblance nombreux qu'ils présentent avec les trouvailles élamites des couches les plus anciennes. . . . (En Egypt) on retrouve des formes, des sujets, des détails de technique qui évoquent aussitôt le souvenir des antiquités de Suse: vases de pierre dure et d'albâtre" (p. 82). M. Pottier discusses the problem in its wider bearings (pp. 83–85), and elsewhere (pp. 67 *et seq.*) sets forth his views on the psychology of originality in invention and of the significance and the manner of cultural diffusion. Though he does not claim that Susa borrowed from Egypt, he is quite clear that the proto-Elamite culture was imported from Susa, and he sets forth the evidence which in fact demonstrates that Egypt must have been the source of its inspiration. On p. 66 he again discusses the antiquity of the proto-Elamite civilization and repeats his remarks about the earliest immigrants into Elam in these words:—"Quand ces envahisseurs s'installèrent sur les faibles hauteurs, de neuf a dix mètres a peine, qui bordaient la rivière (J. de Morgan, *Revue d'Assyriologie*, 1909, p. 2), ils étaient déjà en possession d'une civilization raffinée." They had copper weapons and utensils: their women had mirrors: they had fine clothes, etc.

If it is indeed a fact that Elam was colonized before Sumer, the question naturally suggests itself why the newcomers were not content to exploit the fertile banks of the Tigris and Euphrates, but should have chosen the less attractive and rocky country of Elam for their settlement. The answer to this question has been provided in advance by Mr. W. J. Perry's investigations (*Memoirs and Proceedings, Manchester Literary and Philosophical Society*, 1915) which explain why civilized immigrants in other parts of the world have chosen certain regions to exploit and neglected apparently more attractive places. The Egyptian immigrants into Elam were undoubtedly prospecting for copper ore. In his book *Les Premières Civilizations* de Morgan refers to Elam as one of the two "foyers des inventions métallurgiques" on the ground that copper implements were found in the earliest strata there and the mountains of Elam are "riches en minerais cuivreux" (p. 169). But it was the ore which attracted the foreigners and induced them to settle in Elam.

There is evidence of various kinds to suggest that at or about the time when the Elamite and Sumerian civilizations were founded there was a widespread prospecting of the mineral resources of western Asia and the lands around the eastern Mediterranean. The objects of this search were gold and copper, lapis lazuli and turquoise, pearls and shells.

We have already seen that the proto-Elamites had lapis lazuli and turquoise and suggested that they must have gone as far afield as the Caspian to obtain these stones. That they did actually exploit this region is shown by the results of the Pumpelly Expedition (Ralph Pumpelly, *Explorations in Turkistan*, Carnegie Institution, 1908) in Russian Turkestan, where painted pottery of proto-Elamite type was found in the neighbourhood of certain ancient copper-workings. There can be no doubt that Susian prospectors went to the Caspian area to obtain copper ore, and incidentally got lapis lazuli and turquoise. In the lowest stratum in the northern kurgan at Anau, Pumpelly found hand-made painted pottery, cultivated wheat and barley, turquoise beads, mace-heads, copper and lead, and rectangular houses of sun-dried brick (vol. i., p. 33). At a somewhat higher level he found in addition beads of lapis lazuli and carnelian (p. 42). It was only at a later time (his so-called "Culture 3," found in the southern kurgan at Anau) that pottery turned on the wheel was found: in the same level tin mixed with copper, and evidence of an "intentional alloying with lead" was obtained; also figurines of a goddess and a cow. Of the earliest culture Hubert Schmidt tentatively estimates the age as "in the third millennium," the second in the latter half of the second millennium, and the third approximately 1000 B.C.

Pottier also summarizes (*op. cit.*, p. 71) the whole discussion: "According to Hubert Schmidt (*Revue archéologique*, 1910, i., p. 307) the most ancient pottery from Anau may be contemporary with that of Susa, but he believes it to represent an extension of Elamite art to Turkestan." In a great part of the Transcaspian region of Turkestan "au delà de l'Oxus," north of the Pamir plateau between Samarkand and Kashgar, the finding of objects made of metal or pottery analogous to those of Mesopotamia (Pottier, p. 70) affords additional evidence of the diffusion of Elamite, Sumerian and Babylonian culture in very early times.

It is clear then that the search for copper ore, lapis lazuli and turquoise led to the diffusion of proto-Elamite culture far into Turkestan. But the same reasons led to its spread to Armenia, the Caucasus and Asia Minor in the west and at least as far as Baluchistan, and probably India, in the east.

In Armenia and the Caucasus painted Susian-like vases do occur, but only very rarely (Pottier, p. 73). "Cette poterie du Caucase, dont la date n'est determinée, est sans contredit affiliée par la tradition à la fabrique élamite" (p. 74). In Galatia and Cappadocia painted pottery of the same type is found, which is certainly not of Aegean inspiration (p. 74). Similar pottery is found also in Phrygia and Mysia (p. 76); and M. Pottier suggests that between early times and the period of the eighth and seventh centuries B.C. Susian influence percolated into Phrygia from the neighbouring lands. The geographical lines of the spread of this culture seem to have been determined mainly by the distribution of copper and gold. Elamite pottery has been found north of the Black Sea in Scythia (Pottier, p. 74). Without any definite reasons, so far as I understand his report, M. Pottier thinks that, although the designs upon the painted pottery of the Thraco-Phrygian area are similar to those of the Susian ware, the inspiration was independent. However, he thinks that Lydia and Caria, Syria and Palestine were influenced both by Elam and Egypt about the middle of the third millennium. Once one admits the motive and considers the times of the respective diffusions of culture, the process and the lines of spread become clear enough. When gold and copper acquired in Egypt for the first time an arbitrary value they were sought for far and wide, not merely in the Eastern Deserts of Egypt and Nubia, but also in Arabia and Elam, in Asia Minor, in the Caucasus and Turkestan. From Egypt there were two main lines of diffusion of culture—one E. to Elam and the other N. to Crete[1] and Asia Minor;[2] and from each of these centres secondary lines of radiation were established.

One of the most striking illustrations of the extent of these secondary radiations and of the motives which prompted them is afforded by the remarkable centre of Elamite culture at the little village of Nal (in the Jhalawan district of Kalat state, lat. 27°40′, long. 66° 14′) in Baluchistan (J. H. Marshall, "A New Type of Pottery from Baluchistan," *Survey of India, Annual Report*, 1904–5, Calcutta, 1908, pp. 105 *et seq.*; for summaries see *Revue archéologique*, 1909, p. 156, also Pottier, *op. cit.*, p. 72; Noetling, "Ueber eine prähistorische Niederlassung im oberen Zhob-Thal in Baluchistan," *Zeitschrift für Ethnologie*, 1898, pp. 460–470; also "Ueber prähistorische Niederlassungen in Baluchistan," *ibid.*, 1899, pp. 104–107).

The pottery from Baluchistan is painted with designs clearly analogous to those found at Susa, of the culture of which it is clearly either a contemporary offshoot or a persistent survival. On the evidence supplied by Marshall the latter explanation seemed to be the just one; but Noetling has shown that the Baluchistan pottery occurs in what he calls "Neolithic" sites, and it is quite clear that the Elamite ceramic industry extended as far east possibly in the third millennium. The fact that it was found in association with gold deposits and ancient irrigation works completes the proof of the motives and the identity of the introducers of the ancient civilization. The Baluchistan centre of Susian influence possibly represents a stage in the migration of the knowledge of copper (from Egypt, via Susa and Baluchistan) to India, where an early Copper Age culture

[1] See Diedrich Fimmen, *Die Kretisch-Mykenische Kultur* (1921).
[2] A. E. Cowley, *The Hittites*, The Schweich Lectures for 1918 (1920).

developed on the banks of the Ganges (W. Crooke, *Northern India*, 1907, p. 18: "an age of copper is well marked by finds of implements of remarkable shapes in the Ganges Valley ").

The search for copper or gold attracted these earliest exploiters to Elam, to Asia Minor, the Caucasus and Black Sea littoral, the southern shores of the Caspian and Transcaspia, and to Baluchistan; but it also led them much farther afield. So that, long before the invention of bronze the germs of ancient civilization were planted in Turkestan and along a series of gold-workings from the Oxus to Bukhara, to Issyk-kul and Kulja, to Barnaul, Krasnoyarsk and Minusinsk, which became the centre where for many centuries the civilization of central Siberia flourished in spite of the fact that it was the lure for the greed of a vast continent and the home of strife (W. J. Perry, "War and Civilization," *Bulletin of the John Rylands Library*, 1918).

But it was not merely the chain of golden sands along the line from Bukhara to the Yenisei that attracted the miners from the S., but also the gold and jade in the Tarim valley in pursuit of which the prospectors were led on from Kashgar to Kucha past Lop-nor to Suchan, Liangshan and Lanshan until eventually they discovered the gold and jade in the mountains S. of Si-ngan in Shensi. Settling down to extract this wealth they incidentally planted the germs of the civilization of China. Laufer's memoir on *The Beginnings of Porcelain in China* (1917) (see also his "Some Fundamental Ideas of Chinese Culture," *Journal of Race Development*, vol. v., 1914, pp. 160–174) affords irrefutable corroboration of the fact that "the entire economic foundation of ancient Chinese civilization has a common foundation with that of the West" (p. 175). "It is inconceivable that the (potter's) wheels of India and China should be independent of those of the West" (p. 175). All the facts brought together by Laufer point clearly to the conclusion that the world at large learnt the use of the potter's wheel from Egypt (pp. 174–176). Many centuries later "the incentive for the process of glazing pottery was received by the Chinese directly from the West, owing to their contact with the Hellenistic world in comparatively late historical times. The knowledge of glazing rendered the manufacture of porcelanous ware possible; yet in this achievement the creative genius of the Chinese was not guided by outside influence, but relied on its own powerful resources" (p. 176).

Elamite civilization was diffused to Turkestan long before wheel-made pottery was made, because Pumpelly's excavations revealed the fact that in the first and second of his culture-stages at Anau only hand-made pottery was found.

The routes followed by these early culture-bearers from Persia to central Siberia and to China respectively are mapped out by the remains of ancient irrigation systems. Wherever gold was to be obtained from any of the streams or lakes these wandering prospectors settled to wash the sands for the precious metal: they also irrigated the land in their characteristic way to grow crops to maintain themselves; and they left stone monuments as memorials for their dead. The association of these three classes of evidence, the presence of gold, ancient irrigation and stone monuments, still blazes the paths taken by these ancient prospectors forty or more centuries ago. Detailed statements of two of these classes of evidence will be found in J. Mouchkeboff's *Les Richesses Minérales du Turkestan* (Paris, 1878) and H. Moser's *L'Irrigation en Asie Centrale* (Paris, 1894).

There is evidence of another kind in substantiation of the intimate cultural link between early Egypt, Elam and Sumer, and between them and the Iranian and Turanian domains. The religious ideas and mythology reveal the closeness of the bonds between these ancient centres, and especially the fact that much of so-called early Aryan beliefs and myths are really Egypto-Sumerian in origin.

But reference has been made to the intimacy of the early cultural bonds between Mesopotamia and Turkestan because it has a bearing upon one of the most important episodes in the history of civilization—the invention of the alloy bronze and the inauguration of the Bronze Age. We know that before the invention of bronze prospectors for gold and copper exploited the line of deposits of these metals which forms a chain linking the valley of the Oxus to the upper Yenisei. The rich archaeological harvest collected around the sites of these ancient workings establishes this fact. Now if it be true—and the evidence at present available renders it probable—then the making of bronze was invented with the help of the tin obtained from Meshed. Ancient tin mines were discovered in this region by P. Ogorodnikov (compare Baer, *Arch. f. Anthr.* ix., p. 265], quoted by Terrien de Lacouperie, *Western Origin of Chinese Civilization*, p. 322). "Strabo declares that it (tin) was produced in Drangiana, west of the modern Afghanistan, a district partly coinciding with Khurasan, where its presence has been confirmed. It is also found in other parts of Persia, near Asterabad and Tabriz" (C. H. Read, *A Guide to the Antiquities of the Bronze Age*, British Museum, 1904, p. 9.) The exact spot where tin has been found at the south-eastern corner of the Caspian is indicated by J. de Morgan, *Mission Scientifique au Caucase* (1889).

In her important monograph on *Gournia* Mrs. Harriet Boyd Hawes brings forward the following weighty arguments in favour of the invention of bronze in the southern Caspian area. "When the Pumpelly expedition returned from Turkestan in 1904, one of the members brought potsherds indistinguishable at first sight from the brilliantly mottled ware found at Vasiliki (Crete) during the same season. . . . The strong likeness between the two fabrics . . . is more reasonably explained by intercourse than by accident. Moreover, Dr. Hubert Schmidt . . . reports that a neighbouring tumulus (near the large one in which the pottery was found) gave him a three-sided seal-stone of Middle Minoan type, engraved with Minoan designs—man, lion, steer, and griffin. How shall we explain those evidences of Aegean influence in southern Turkestan? They must be brought in line with other proofs of contact. . . . We see that at *c.* 2500 B.C. Asia Minor shared with the Aegean the knowledge of bronze . . . we may suggest the probability that, long before tin was discovered in Europe, it was being brought overland through Asia Minor, and also by way of Transcaucasia and the Black Sea from distant Khorassan, Strabo's Drangiana. . . . Excavations at Elizabethpol in Transcaucasia have revealed a culture in early contact with the Aegean."

One of the results of this intercourse between Turkestan and Asia Minor was the introduction into Europe of the appreciation of jade, which no doubt was responsible for stimulating the people of Europe to hunt out and work the supplies of nephrite which occur locally.

Terrien de Lacouperie makes the following statement:—

"The precious nephrite (polished celts) is found along the route from Khotan in Turkestan, its starting point, to the Jaxartes, to the Oxus, then S. of the Caspian Sea, in Babylonia and Assyria, along the Northern Asia Minor shores, bordering upon ancient Troy, then passes to the Peloponnesus, where it directs its course to Crete, and, not touching Egypt, passes from Greece to Italy, where it is distributed among the Helvetian Lakes, the Megalithic monuments of Armorica, etc." (*Western Origin of Chinese Civilization*, p. 34.)

Chinese Civilization.—There is no doubt that the cradle of Chinese civilization was in the Shensi province early in the third millennium, and that the inspiration of this culture was provided by miners from the W. who were exploiting the gold, copper and jade of the mountains S. of Si-ngan-fu, and incidentally planting in China the much modified elements of Elamite civilization which had been handed on from one mining camp to another on the long route to China.

The occasional use of jade for seal-cylinders in Babylonia and the value attached to turquoise there suggests that the people who were washing the sands of the Oxus, the Syr Daria, Issyk-kul and the Ili for gold—and the presence of distinctive types of ancient irrigation works on the banks of these waters proves the reality of such exploitation—were also working the Tian Shan range and the neighbourhood of Khotan and Kashgar for jade and turquoise. What strengthens the belief in the reality of this suggestion is the fact that the peculiarly arbitrary and distinctive magical significance which was attached to pearls

and gold by the early sailors of the Erythraean Sea was acquired also by jade. The only reasonable suggestion that explains this remarkable circumstance is that these ideas were acquired by the people of Turkestan from Mesopotamian miners, and that the former came to attach to *all* the materials for which the immigrants were searching the peculiar attributes which these immigrants themselves assigned only to certain of them. Hence jade came to be regarded, like pearls, as the giver of life and resurrection and as a preventive of putrefaction of the corpse.

The problem that must be solved in the explanation of the symbolism of jade in China is the source of its inspiration. Why should jade be regarded as the giver of life and resurrection, the preserver of the dead and the bringer of good fortune? We know how and why the pearl came to acquire these magical attributes. We know also that the ancient Persian word for a pearl, *margan*, "the giver of life," was adopted in all the Turanian languages; so that the word and the idea underlying it spread E. as far as Kamchatka. The exact identity of the ideas concerning (and the methods of using) jade suggest that they must be derived from the pearl-symbolism, and the tentative explanation suggests itself that the people of Mesopotamia exploited the area in the neighbourhood of the Tian Shan mountains for gold and jade, and so transmitted to the people of Chinese Turkestan ideas of the magical properties of jade which in course of time spread due E. to the head-waters of the Hwang-ho river.

"The mountains south of Si-ngan-fu in Shensi Province produced jade, gold, silver, copper and iron in the first century B.C., as expressly stated in the *Annals of the Former Han Dynasty* . . . the distinguished physician T'ao Hung-King (452-536 A.D.), the author of a treatise on *Materia Medica* (*Ming i pieh lu*), states that the best jade comes from (Lan-t'ien): he mentions also the occurrence of jade in Nan-yang, Honan Province, and in the Lu-jung river of Tonking, also that brought from Khotan and Kaskgar" (Laufer's *Jade*, p. 24).

Laufer denies that jade was imported into China from Turkestan before the commencement of the Christian era; and also seems to be opposed to the idea that the magical value attached to jade in China was suggested by the West.

"While from about the Christian era Turkestan became the chief source for the supply of jade to China, to which Yunnan and Burma were later added, neither Turkestan nor Yunnan came into question in very early times. The jades used in the period of the Chou, and most of those of the Han Dynasty, were quarried on the very soil of China proper. It was doubtless the Chinese themselves who, being acquainted with jade in their country, probably for millenniums, gave impetus to the jade fishing and mining industries of Turkestan. Also this case may throw a side-light on the nephrite question of Europe: home-sources do not exclude imports, and scarcity or exhaustion of sources may favor them" (Laufer, *Jade*, pp. 23 and 24).

But Laufer's hypothesis of the origin in China of the special appreciation of jade will not bear examination. The search for gold in Turkestan was certainly begun by people from the South. There can be no doubt that the same people who washed the sands of these rivers of Turkestan for alluvial gold and fresh-water pearls also inaugurated the practice of "fishing for jade." The proof of this inference is provided by the fact that jade acquired precisely the same reputation and had attributed to it the same remarkable repertory of magical properties as these southern miners associated with pearls and gold.

Dr. Laufer himself puts the matter in its true perspective when he is discussing the problem of European jade (p. 5). His argument is so apt and incisive that it is tempting to use it to demolish his own hypothesis:—

"Nothing could induce me to the belief that primitive man of central Europe incidentally and spontaneously embarked on the laborious task of quarrying and working jade. The psychological motive for this act must be supplied, and it can be deduced only from the source of historical facts. From the standpoint of the general development of culture in the Old World, there is absolutely no vestige of originality in the prehistoric cultures of Europe, which appear as an appendix to Asia. Originality is certainly the rarest thing in this world, and in the history of mankind the original thoughts are appallingly sparse. There is, in the light of historical facts and experiences, no reason to credit the prehistoric and early historic populations of Europe with any spontaneous ideas relative to jade; they received these, as everything else, from an outside source; they gradually learned to appreciate the value of this tough and compact substance, and then set to hunting for natural supplies."

Substitute "China" for "central Europe" in this admirable statement, and it applies with equal force. For the Chinese had no reasons for attaching a special value to jade until they were inspired to do so by ideas which came to them from elsewhere. Laufer claims that the question can only be settled on the basis of historical fact. His argument also implies that the idea of working jade spread from one centre. In other words, if we accept his teaching, the use of jade in Europe during the early Bronze Age was inspired by events in the Shensi province of China! What historical evidence is there, first, for assigning such a remote date for the exploitation of jade in China, and, secondly, for the transmission of the knowledge of these events from China to Switzerland nearly 40 centuries ago?

In Turkestan we find definite reasons for the appreciation of and the commencement of the working of jade. We have also found some evidence to justify the hypothesis that the making of bronze was invented in close proximity to Turkestan. The people who introduced the knowledge of bronze-making into Europe, also introduced the appreciation of jade.

If, however, we accept Laufer's view that Chinese culture inspired the appreciation of jade in central Europe in the second millennium B.C., or even earlier, presumably the channel passed *via* Turkestan. Part of his argument (see above) was based upon the fact that the Chinese jade traffic with Turkestan was unknown before the beginning of the Christian era. But if there was this early intercourse with Turkestan, the fact that the Babylonians or whoever was exploiting the wealth of that country, attached a special value to gold, pearls and jade can hardly be left out of account in considering the origin of Chinese ideas. Is it likely that the exact coincidence between these wholly arbitrary ideas in China and Babylonia respectively were independent the one of the other? Dr. Laufer himself rightly scouts the idea of such independent development. If so he must admit that the Chinese ideas concerning jade must have been inspired by the West.

Light is thrown upon these problems by the study of the metal implements found in Siberia and elsewhere. In his admirable *Guide to the Antiquities of the Bronze Age* (British Museum, 1904), Sir Hercules Read summarizes the evidence in an impartial manner[1]:—

"At the extremities of the vast area stretching from Lake Baikal through the southern Siberian steppes across the Ural Mountains to the basin of the Volga, and even beyond to the valleys of the Don and Dnieper, there have been found, generally in tombs, but occasionally on the surface of the ground, implements and weapons marked by the same peculiarities of form and by a single type of decoration. These objects exhibit an undoubted affinity with those discovered in China; but some of their distinctive features have been traced in the Bronze industry of Hungary and the Caucasus: for example, pierced axes and sickles have a close resemblance to Hungarian and Caucasian forms. The Siberian bronzes have thus relationships both in the East and West; but their kinship with Chinese antiquities being the more obvious, it is natural to assume that the culture which they represent is of East Asiatic origin. The presumable antiquity of Chinese civilization (which after all is only a presumption); the continued westward tendency of migration in historical times (which, however, were started by the disturbances in the gold region of the Altai,[2] and therefore tell against Sir Hercules Read's argument); and the fact that the greatest centre of discovery lies far away to the East in the basin of the Yenisei, in the districts of Minusinsk and Krasnoiarsk, are all points which may be urged in support of this view."

To the objections which we have interpolated in this quotation, Sir Hercules Read himself adds others. The Chinese implements are "not of primitive forms":—

"Their prototypes are found neither in the Ural-Altaic region itself, where some objects may indeed be simpler in design than others but cannot be described as quite primitive; nor as yet within the limits of China itself" (p. 107).

[1] Pages 106–111 compare also the fuller and more recent summary of the evidence in the book by Minns, *Scythians and Greeks*, in which, however, the statement is marred by an uncritical acceptance of the dogma of independent evolution of culture.

[2] See Perry's Rylands Library Lecture, *War and Civilization*.

"The true solution of the problem will be reached when it is recognized that the basin of the Yenisei and China represent the two termini of a stream of culture which passed N. from the southern end of the Caspian Sea and divided at the Tian-Shan range into two branches, one of which passed more immediately to the Yenisei and the other *via* Khotan and Kashgar ultimately to China. Sir Hercules Read hints at the possibility of this explanation without, however, definitely committing himself to it:—

"The similarities existing between the Far Eastern and Hungarian groups will not be fully explained until the Bronze Age of southern Asia as a whole is far better known than it is at present (1904). According to a view which has found some acceptance, the common elements may have been derived from some centre in southern or south-western Asia, from which issued two streams of influence, one passing to the N. of the Caucasus, the other to China by a southerly route" (p. 109).

Further, in his account of the Siberian implements, Sir Hercules Read adds:—

"The most characteristic ornament represents animals of local species, bears, reindeers, wild goats, etc., the monsters characteristic of the later Iron Age tombs being absent. Sometimes the heads of animals are placed back to back so as to form the guards of daggers, a disposition which has some resemblance to those of daggers represented upon Assyrian monuments" (p. 110).

Correlating all the facts and suggestions brought together by de Morgan, Pumpelly, Laufer, Read, Hawes and Minns, and interpreting them in the light of Perry's illuminating demonstration of the vital part played by the search for gold, copper, pearls and precious stones, we find the general explanation seeming to emerge quite definitely, even if the details still remain to be worked out.

From the third millennium the mines on the S.E. of the Caspian were being exploited and contact was established between Babylonians, Elamites and the population of Turkestan. The northerly extension of Mesopotamian cultural influence established further contact with the Mediterranean in the West, and both directly and indirectly with the strip of rich metalliferous country stretching along the Caucasus from the eastern coast of the Black Sea to the Caspian. At the same time, from the eastern and south-eastern shores of the Caspian there was a further extension of mining activities E. and N.E. to the Oxus, to Samarkand and Ferghana, and to the S.E. of Lake Balkash. From the great southern Caspian centre of the Bronze industry there were drifts of cultural influence to the Aegean and the Black Sea, to Turkestan and China itself.

The invention of the alloy bronze was an event of most momentous importance in the history of civilization; the determination of the exact place whence the knowledge of this procedure was diffused to the ends of the earth is therefore a point of exceptional significance: hence the facts and arguments which point to the neighbourhood of the Caspian early in the third millennium as the place and time of this event have been set forth here in some detail.

Social Organization and Totemism.—One of the most potent factors in shaping the beliefs and customs of the world at large was the result of an ingenious device on the part of the priesthood of Heliopolis to attain their own selfish aims, namely, of increasing their political power and influence and enhancing their social status. Until the period of the Fourth Dynasty in Egypt the royal family controlled the whole of the priestly and administrative functions of the State. The king was the high priest and his eldest son the grand vizier. Each of the administrative districts of the State—the nomes—was governed by a member of the royal family. Hence the whole government of the State was concentrated in the hands of one family. But from the earliest times the priesthood of Heliopolis had played an important part in Egypt. They were responsible for the astronomical calculations necessary for the prediction of the annual flood of the Nile, on which the welfare of the whole country depended. At Heliopolis the first nilometer was set up, and in all probability the first solar calendar was devised there. In course of time it became the centre of the solar cult which superseded (or rather adopted and profoundly modified) the Osirian belief in the river as the source of all life. Having built up the solar theology at the end of the Fourth Dynasty, the priesthood of Heliopolis made a bold bid for power by putting forward the prophecy that Re, the sun god, would be the father of the first king of the Fifth Dynasty by the wife of the high priest of Heliopolis. Hence arose the custom of regarding the chosen people as "children of the sun" and believing in the virgin birth of kings and gods—arbitrary elements of culture the widespread distribution of which throughout the world is a striking token of Egyptian influence in the upbuilding of civilization. The ingenious device of the Heliopolitan priesthood to seize control of the State was not wholly successful, but resulted in a dual organization of the Government, the Heliopolitan family controlling the priestly duties and the Memphite (the old royal) family the civil administration. This splitting of responsibility and control led to a rapid disintegration of the governing power and at the end of the Sixth Dynasty the State was reduced to a condition of anarchy. But the effect of this remarkable experiment in government became widely diffused beyond the boundaries of Egypt; and the dual organization of the community and the use of such phrases as "son of the Sun" were carried far afield, even to Oceania and America. In the whole extent of the regions from Egypt to America we find traces of two well-marked phases of civilization. The earlier represents a form of social organization essentially identical with that of Egypt of the Fifth Dynasty:—sun-cult; a dual kingship, one ruling family being concerned with secular and another with priestly functions; and a dual division of the State, which even extends to individual villages. It seems probable that the priesthood which originally devised this dual organization realized the danger of the cleavage and the risk of disintegration inherent in it, and introduced the principle of exogamy to maintain the coherence of the community that was split into two conflicting moieties by compelling the members of the divisions to intermarry.

In many places this phase of culture gave place to another derived directly from it by a process of inevitable disintegration following on the splitting off of daughter settlements. In this secondary process the sun-god became known as a war-god: the kingship ceased to be dual, and the dual organization of the State and the village tended to disappear with greater or less rapidity according to local circumstances.

In the early phase of dualism the two rulers were assisted in the administration by a council, the members of which were the representatives of local groups (the Egyptian nomes), usually clans associated with some animal from which they claimed descent. (The reason for this remarkable belief, known as totemism, is probably to be found in the fact that the earliest Egyptians regarded the milk-giving cow not merely as a foster-mother but as the actual Great Mother of mankind. When the nomes adopted as badges a series of distinctive animals, these maternal functions were attributed to all of them.) Like the kingship this totemic council was also dual, one section being concerned with peace and the other with war. It often happened that the ruling power disappeared and then we find that the people deliberately maintained the council as the proper means of preserving the constitution with which they are familiar. Thus is produced a state of affairs commonly called the dual organization in which the country is divided into two parts with different characteristics. Just as in Egypt one kingdom was known as the white crown and the other as the red, so in many parts of the world one moiety is connected with the colour white (or a light colour) and the other with red (or a dark colour). One is associated with the sky and with peace and is regarded as superior, the other with the earth, the underworld, and war and is regarded as inferior.

A feature of the dual organization is the council of old men—the gerontocracy—which is regarded as of the utmost importance. The various groups of the dual organization in its pure form appear to be what are called totemic clans. The basis of this system is to be found in the doctrine of theogamy, which as we have seen was invented by the priests of Heliopolis to serve their own personal ends.

There was a vast amount of speculation during 1910–20 as to the meaning of totemism, an impartial and full summary of which has recently been published by Dr. Arnold van Gennep (*L'État Actuel du Problème Totémique*, Paris, 1920). But recent research (and especially the unpublished researches of W. J. Perry, which the present writer has been permitted to see and use) makes it abundantly clear that, wherever it is found, totemism has been derived directly or indirectly from the beliefs and practices associated with the ruling classes in Egypt during the Pyramid Age, to which reference has already been made. When one investigates the more primitive forms of totemism and realizes the part played in them by such ideas as matrilineal descent from animals, virgin birth, children of the sun, and the belief in the protective value of animal crests, there can no longer be any doubt as to the derivation of these conceptions from Egypt of the Fifth Dynasty.

In the foregoing account it has been claimed that a very intimate connexion exists between the dual organization and the system of totemic clans. This is not an accidental circumstance, as is often assumed, but is the inevitable result of the conditions under which the dual system arose in Egypt. No doubt this will be regarded as a very heterodox claim; but the facts in proof of it are certain and their meaning quite conclusive. Although the dual organization now survives only in India, Oceania and America, there are marriage customs with a much wider distribution, notably in Africa, which point to the influence of this social system in earlier times. In Australia there are very complicated systems of rules to regulate marriage: but in many tribes they afford a very striking demonstration of the original connexion between the dual system and the totemic clans. The dual chieftainship still persists in Polynesia and New Guinea, as it did in Japan until the Shogunate became virtually extinct a few years ago. According to Géza Róheim (*Man*, 1915, p. 26) there are very definite traces of the same customs among the Ural-Altaic peoples. He refers especially to the double kingship of the Khazars as being essentially similar to the Mikado-Shogun system of Nippon.

The vast importance of the study of social organization has been emphasized by Dr. W. H. R. Rivers within recent years (*Kinship and Social Organization*, London, 1913; *History of Melanesian Society*, Cambridge, 1914), and in his hands the use of the data relating to marriage regulations and relationship has become a most valuable instrument for investigating the problems of ethnology and the diffusion of culture. (G.E.S.)

ANTISEPTICS (*see* 2.146).—During recent years the study of antiseptics has proceeded mainly along two lines—attempts have been made to produce more efficient antiseptics for use in the ordinary way by external application, and chemical substances have been elaborated which when injected into the circulation destroy the microbes with which they come in contact. At the same time many studies have been made on the natural antiseptics by which the body rids itself of infection.

Antiseptics Naturally Occurring in the Human Body.—It is well known that we are constantly coming in contact with disease-producing microbes and yet only comparatively rarely does an infection result. It is also well known that an individual who has been living in a secluded spot which was comparatively free from infection, when brought into a city where infection is common, is very much more liable to infection than an individual who had been living in the city. The latter by coming in contact with the microbes has developed a partial immunity to the common infections, so that, while the stranger will rapidly succumb to the infecting microbe, the partially immune person will be able in many cases to resist it. This immunity is due to an increase in the amount of anti-bacterial substances of the body fluids, and to a better organization for the mobilization of the defences of the body towards the point of attack.

In the simplest cases, where microbes are introduced into the body by the instrument which inflicts the wound, there is very quickly produced a dilatation of the surrounding blood-vessels which increases the blood supply to the infected region. This is followed by an increased transudation of the fluid portion of the blood from the vessels into the infected tissues, and by an emigration from the blood of the white corpuscles or leucocytes, which are amoeboid bodies capable of ingesting the microbes and destroying them.

With some infecting agents such as the typhoid bacillus the fluids of the blood have a great power of killing the microbes, but in most of the commoner infections this power is not so manifest and the leucocytes are the chief agents in their destruction. The quality of the fluids even in these cases is, however, of great importance in preventing the increase of the microbes, and in acting on them so that the leucocytes can readily take them up and complete their destruction. Almroth Wright has shown that in cases of severe infection the power of the blood serum to neutralize tryptic ferments (the antitryptic power) is much increased, and by virtue of this increased antitryptic power the growth of the microbes is greatly hindered in the serum. He has shown also that the alkalinity of the blood is of great importance in retarding the growth of some microbes such as those which cause gas gangrene. He has also shown that the serum will act on the microbes by virtue of its opsonic action so that they can be taken up by the leucocytes and destroyed. These observations on the opsonic power of the serum form the basis for modern vaccine-therapy, which has been of such benefit in combating many infections.

It has been shown that the leucocytes of the blood, and also the leucocytes which exude from the blood into an infected wound and constitute pus, have a very powerful action in destroying the ordinary septic microbes, and these natural antiseptics have the great advantage over the chemical antiseptics that they act mainly on the microbes which are imbedded in the tissues, and not merely on the microbes on the surface of the wound. In all wounds in which an infection has been established the majority of the microbes are in the tissues well below the surface of the wound, and are quite inaccessible to chemicals applied to the surface.

During recent years research has been directed to the action of chemical antiseptics on the natural defences of the body, and it has been shown that the cells of the body are more susceptible to the chemicals and are more easily killed by them than are the microbes, so that it is clearly impossible to kill by means of one of the ordinary chemical antiseptics the microbes imbedded in the tissues, unless at the same time the tissues are destroyed.

Chemotherapy.—The ideal method of using an antiseptic is to introduce it into the circulation so that it reaches every portion of the infected focus and destroys the microbes. For the ordinary bacteria this ideal had not yet been attained in 1921, but remarkable advances had been made in this direction in certain infections. In 1910 Ehrlich prepared an organic arsenical product which when injected into the body rapidly destroyed the microbe of syphilis, and this product, salvarsan, or a later and more easily administered product of somewhat similar constitution, neo-salvarsan, has revolutionized the treatment of this disease. Following Ehrlich, Morgenroth prepared a chemical substance which had a remarkable affinity for the pneumococcus (the microbe which causes pneumonia), and destroyed it in very high dilution, whereas it had little lethal action on other bacteria. It was found that Morgenroth's drug (optochin) lost much of its lethal power on the pneumococcus when injected into the animal body, and also it had certain poisonous effects on the animal tissues, so that in practice it had not been useful. The fact, however, that drugs can be prepared that have a very specific action on one microbe offers some hope that in the future there will be produced chemicals which will be able to destroy the ordinary disease-producing bacteria, without damaging the tissues, and so give us an easy and certain remedy for the common infections.

Chemical Antiseptics for Application to the Wound.—Prior to the World War the use of antiseptics in surgery had been largely discarded in favour of "aseptic" methods, in which the aim was to prevent the access of the microbe to the wound. During the war, however, it was found that all wounds were infected with septic microbes, and many antiseptic methods

were employed in the hope of destroying these microbes. At first, antiseptics such as carbolic acid and iodine were used, but they were found to be ineffective in preventing the spread of the infection. Then antiseptics of the chlorine group which were derived from bleaching powder came into vogue, and these were found to be much more useful, although their exact value was obscured by the great advances made in the surgery of the wounds at the same time. These chlorine antiseptics act very quickly on the microbes, but at the same time they are very rapidly destroyed in the wound, so that after about 10 minutes they have lost their antiseptic value. It was the common practice to instil these antiseptics into a septic wound every two hours in the hope of keeping up a constant supply of the antiseptic, but as the active agent is destroyed in about 5 or 10 minutes it follows that for the greater part of the time there was no antiseptic in the wound. Fleming has shown that in all probability the beneficial action of these so-called antiseptics was not in their power of destroying microbes but in their power of aiding the natural antiseptic defences of the body.

In the simplest form these chlorine antiseptics were solutions of hypochlorous acid (ensol) or sodium hypochlorite (Dakin's fluid), but later Dakin introduced more complicated organic preparations, such as chloramine T. and dichloramine T., which were more stable and contained a greater percentage of the active agent. These later applications have never attained the popularity of the simpler compounds.

Morison introduced into war surgery a procedure in which the wound, after being thoroughly cleansed, was rubbed over with a paste consisting of bismuth, iodoform and paraffin (Bipp). This obtained a considerable popularity, and it was supposed to act by virtue of the iodoform, which is not in itself an antiseptic, being broken down in contact with the blood fluids with the liberation of iodine. Experiments showed, however, that there was not sufficient iodine liberated to act as a lethal agent for bacteria in the body fluids, and it is probable that, like the chlorine antiseptics, this depended largely for its beneficial action on its power of aiding and conserving the natural defences of the body.

The last types of antiseptics to be introduced into war surgery were the aniline dyes. The power of some of these dyes as antibacterial substances had been previously investigated. Churchman had shown that gentian violet would kill many varieties of bacteria (those which stain with Gram's method) in a dilution of 1 in 1,000,000, or less, while it had little lethal action on other varieties which did not stain by Gram's method. Another dye, brilliant green, had been used in bacteriological technique for the isolation of typhoid bacilli, owing to its having a less lethal action on these than it had on the other and more common bacteria. Browning introduced into surgical practice another dye of the acridine series, called by him flavine or acriflavine, which had been originally prepared by Benda at Ehrlich's suggestion for the destruction of trypanosomes (the parasites of sleeping-sickness). Flavine differed from all the other antiseptics in that it acted more powerfully in the presence of blood serum than it did in water. Great hopes were therefore entertained that it would be able to deal effectively with the bacteria in an infected wound. It was found, however, that it was rapidly fixed by the body tissues and by the dressing of the wound, and in practice it was not found to have advantages over the other antiseptics in common use.

Towards the end of the war all the chemical antiseptic solutions fell more or less into disuse and more reliance was placed on efficient surgery and the natural antiseptics of the body. The greatest advance in the treatment of infected wounds was the efficient cleansing of the wound, the removal of all dead tissues, and the immediate closing of the wound so that the natural antiseptic defences could exercise their functions to the greatest advantage. It was found that when physiological salt solution was used the results of this procedure were as good as when chemical antiseptics were employed.

Since the war conditions have been removed antiseptics have largely disappeared from surgical practice, and a return has been made to "aseptic" methods, in which microbes are, as far as possible, excluded from the wound and the natural defences of the body are left to deal with the few microbes which may gain access. (A. Fl.)

ANTOINE, ANDRÉ (1858–), French actor-manager (*see* 2.148), opened in 1897 his Théâtre Antoine in Paris, which for 10 years he made famous as a home of modern realistic drama, playing in particular the works of Brieux, Hauptmann and Sudermann, and staging a French version of *King Lear*. He returned to the management of the Odéon in 1906 and there produced *Julius Caesar*, *Coriolanus* and a large number of classical and modern dramas, but he retired in Feb. 1914. He was subsequently engaged in writing his memoirs.

ANTWERP, Belgium (*see* 2.155).— Pop. (1914) 313,833; but, including Borgerhout (52,126) and Berchem (32,257), total pop. 398,216. The projected *grande coupure*, or cutting through the neck of the loop in the river Scheldt immediately below Antwerp, was abandoned, and, in place of this scheme, three extensive wet-docks were constructed between 1903–14. In 1913, 7,142 vessels of aggregate tonnage 28,270,000 entered the port as compared with 6,095 of 10,662,000 tons in 1905. The decision, taken in 1878, to change Antwerp from a fortress to a fortified position by the construction of an outer line of 15 forts and batteries at a distance varying from 6–9 m. from the enceinte was nearly completed at the outbreak of the World War in 1914. A proposal to connect the two banks of the river by a tunnel under the Scheldt was about to be taken in hand in 1921.

On Aug. 17 1914 the Belgian Government left Brussels for Antwerp, and the Belgian army withdrew before the advance of von Beseler's army behind the fortified lines. The bombardment of Antwerp began on Sept. 28 and lasted until Oct. 9, when the city surrendered. Nine-tenths of the population fled, mostly to Holland. Some 300 houses (especially in the Marché aux-Souliers, the Avenue d'Amérique and the suburbs near the forts) were destroyed, but the older and more important public buildings (the positions of which were known to the Germans) escaped damage. Under the harsh occupation of the Germans, Antwerp remained practically a dead city. On Nov. 19 1918, the King and Queen of the Belgians entered the city in state and attended a Te Deum in the cathedral. In Aug.-Sept. 1920, the Olympic Games (7th Olympiad) were held in a newly constructed stadium at Beerschot just outside the city.

The Siege of 1914

In the middle of the 19th century, the steady development of the city and its naval installations had made it necessary to enlarge the fortress, and so disquieting were the ambitions of the new French Empire that it was decided to erect a national keep for the defence of Belgium at Antwerp. The new fortress was accordingly built between 1859 and 1870 under the direction and after the plans of the celebrated Belgian engineer, Gen. Brialmont.[1]

It comprised: (1) A line of detached forts (forts No. 1 to No. 8 and Fort Merxem on the right bank; Forts Cruybeke, Zwyndrecht and Ste. Marie on the left) placed at a distance of about 2¼ to 3 m. from the agglomeration of buildings, so as to protect these against bombardment. These forts, about 2,200 yd. apart, built both in masonry and in earth, were big batteries which embodied the lessons of the siege of Sevastopol. (2) A polygonal enceinte carried round the edge of the city.

With over 1,000 guns the entrenched camp of Antwerp was considered the most powerful fortress in the world. After the lessons of the sieges of 1870–1 and 1877, however, it was considered necessary to extend the fortress's sphere of influence still further, in order to facilitate the operations of the Belgian army when manoeuvring under its protection, and especially to enable it to make sorties in the direction of Brussels or in that of Louvain without being cut off. As the water-line formed by the rivers Nethe and Rupel considerably impeded such operations between Lierre and the Scheldt (that is to say, on that part of the front which was most convenient for them), the forts of

[1] A general plan of Brialmont's fortress and details of its enceinte will be found in 10.693-694.

Waelhem and Lierre and the Chemin de Fer redoubt were constructed S. of the Nethe as a sort of bridgehead. Meanwhile the demands of the port were growing, and the city was becoming cramped within its enceinte. It was therefore decided about 1900 to extend the defensive system still further.

The scheme adopted by the legislative chambers in 1906 provided for:—

(1) The creation of *a principal line of defence*, composed of detached forts about 5 to 11 m. from the limits of the Antwerp agglomeration, to shelter the city from bombardment by the artillery of that epoch. This line was, on an average, about 2 m. in front of the Rupel-Nethe water-line, thus placing the crossing points of this line out of reach of heavy field artillery. Its total perimeter was 59 m., 46 m. on the right bank and 13 m. on the left, of which 6 m. were protected by inundations.

The forts, 17 in number, were disposed about 3 m. apart, and, in principle, permanent redoubts were to be built in the intervals. The forts were armed with one or two cupolas for twin 15-cm. guns, two cupolas for single 12-cm. howitzers, and four or six cupolas for single 7·5-cm. guns. The redoubts had only one 7·5-cm. cupola. Forts and redoubts were constructed entirely of ordinary concrete, with vaults 2·50 metres thick at the crown and surrounded by wet ditches, 33 ft. wide. They all had traditores or "Bourges casemates" flanking the intervals with 7·5-cm. Q.F. guns. The garrisons varied from 100 to 500 men.

(2) The creation of an *enceinte de sûreté* on the old fort line, the forts being organized for small weapons. Concrete redoubts were built at intervals of about 500 yd. and all these *points d'appui* were connected by a grille. This line of defence was to be 20 m. long and 5 to 7½ m. removed from the first line of defence.

(3) The demolition of the elaborate enceinte built in 1859 in the immediate vicinity of the town.

(4) Additional defences on the Lower Scheldt, including several coast batteries level with Doel to sweep the reaches of the river up to the Dutch frontier.

These very extensive works had necessarily to be spread over several years, and in 1914, on the outbreak of hostilities, the transformation of the fortress had not been completed.

(1) Even if the organization had been carried through according to plan, the fortress would not have come up to the standards established by the siege of Port Arthur. The two positions of defence were too *shallow* in themselves and also too far apart to support one another. The *points d'appui* of these positions, in which the elements of permanent defence were concentrated on a small ground surface, very easy to locate, were conceived on a vicious principle. Monolithic concrete is not invulnerable to present-day siege artillery; the organs of defence should therefore be protected above all by their dissemination, by camouflage and by their irregular dispersion over a large surface on the principle of the Metz *Feste*.

The substructures and the armouring, constructed to resist the 21-cm. mortar, were not calculated to face 28-cm., still less 30·5 and 42-cm. projectiles.[1]

(2) In July 1914 not one of the forts planned in 1906 was finished. Some lacked cupolas. Others had cupolas without concrete aprons, and these had to be improvised by pouring gravel, iron rods and cement round the cupolas. In some cases sacks of cement soaked with water, or even simple sandbags, had to suffice.

The transmissions and canalizations were not established either inside or outside the forts, neither was the machinery in place.

(3) For reasons of economy the 15-cm. cupolas had been provided with old guns, formerly on wheeled carriages, which had a range of not more than 8,800 yd. and used black powder. The most recent guns, amongst them those of the traditore batteries, hastily installed, were for the most part without laying instruments. Of the other guns available the most powerful was the 1889 model 15-cm. which had a range of 11,000 yards.[2] Older guns or howitzers, of 12 or 15 cm. were also available, all using black powder. England sent six 4·7 Q.F. guns, mounted on armoured railway trucks, and, in the last days of the siege, six 6-in. guns. No equipment for observation of fire and no observation posts existed, and the necessary survey work for firing by the map was incomplete. There were ten aeroplanes and one balloon for the fortress and the field army together.

The supply of ammunition was extremely modest, the 15-cm. guns being provided with 800 rounds, the others with only 125. Some French ammunition was hurriedly obtained, but, not being designed for the guns, it speedily put them out of action.

(4) The fort garrisons were chiefly of the oldest classes. The Lebel rifle with which they were armed was strange to them and they were entirely ignorant of the machine-gun. The men of the fortress battalions which garrisoned the intervals had had no military service for 10 years or more and their fighting value was very low. The cadres were entirely inadequate.

Unfinished works, conspicuous and concentrated, proof only against projectiles of 21 cm.; obsolete artillery, lacking in observation-posts and in munitions; a garrison full of goodwill but with inadequate cadres and untrained in the handling of modern weapons—such were the real means of defence of the legendary fortress of Antwerp in 1914.

None the less the Belgians displayed, from the moment when their territory was invaded, the utmost activity in preparing it. The unfinished forts were put in a state of defence by any means that came to hand. The aprons for the cupolas were banked up as best they could be. Distribution systems were created for motive power, lighting and telephones. The immediate foreground was cleared, though this did more harm than good, as it made the works very visible. The inundations were prepared. Forts and redoubts were united by continuous wire. In the rear infantry trenches were constructed, but these inevitably showed well above ground on account of the water-level in the soil, and the shelters, which were none too numerous, were made merely with logs. The reserve artillery of the fortress was established in battery positions, which gave an average of five old-pattern guns, firing black powder, per km. of front.[1] A supporting position along the whole length of the Nethe was put in hand. The old fort line, and even the enceinte (which had been only partially demolished), were also organized as far as possible.

The unfinished state of the fortress and the mediocrity of its armament formed a serious handicap to the important part which Antwerp was destined to take in the operations.

(1) As a great commercial metropolis, always abundantly supplied with products of all kinds, Antwerp was an obvious centre for military depots and stores. Containing all the army's arsenals and supply magazines, it was a base of operations from which the army could under no circumstances allow itself to be cut off.

(2) By reason of its situation Antwerp offered to the Belgian field army a stronghold from which it could sally forth at any time it chose, to threaten the lines of communication of the German armies operating in the north of France.

(3) Through Ostend and Zeebrugge Antwerp had easy means of communication with England. Under the shelter of the fortress and the Scheldt English troops could safely land in Flanders, act in liaison with the Belgian army, operate against the German lines of communication, protect the Pas de Calais coast with its sea traffic, vital to England, and prevent the Allied left wing from being turned and enveloped.

To fulfil these important missions the fortress should have been complete and well manned. Failing these two conditions, it was of no importance save for the presence of the Belgian field army within its walls.

The Belgian army had fallen back in the direction of Antwerp when, to avoid envelopment by the German I. and II. Armies, the Nethe position had to be evacuated (Aug. 18–20). Hence, too, after the sortie battles of Aug. 25 (Eppeghem, Hofstade, Werchter) and Sept. 9–12 (Aerschot, Haecht, Louvain) undertaken for the purpose of coöperating in the battle of the Frontiers and that of the Marne, the army returned in each case to the fortress, resolved to stay there as long as its communications with the sea were not in danger.

When the German I. Army wheeled through and past Brussels on its way to France, it dropped the III. Res. Corps (v. Beseler) to face northward as a flank-guard against the Belgian field army at Antwerp. With some additions and changes, Beseler's force[2] remained on the defensive, fulfilling this duty on the line Grimberghen-Over de Vaert-Aerschot.

On Aug. 25 and again on Sept. 9 it had to meet serious sorties of the field army in Antwerp, and on the second of these occasions its situation was at one time critical. After this, for a few days, the front was quiet. But towards Sept. 20 reports began to come in of important German transport moves and of a quantity of very heavy artillery moving on the roads leading

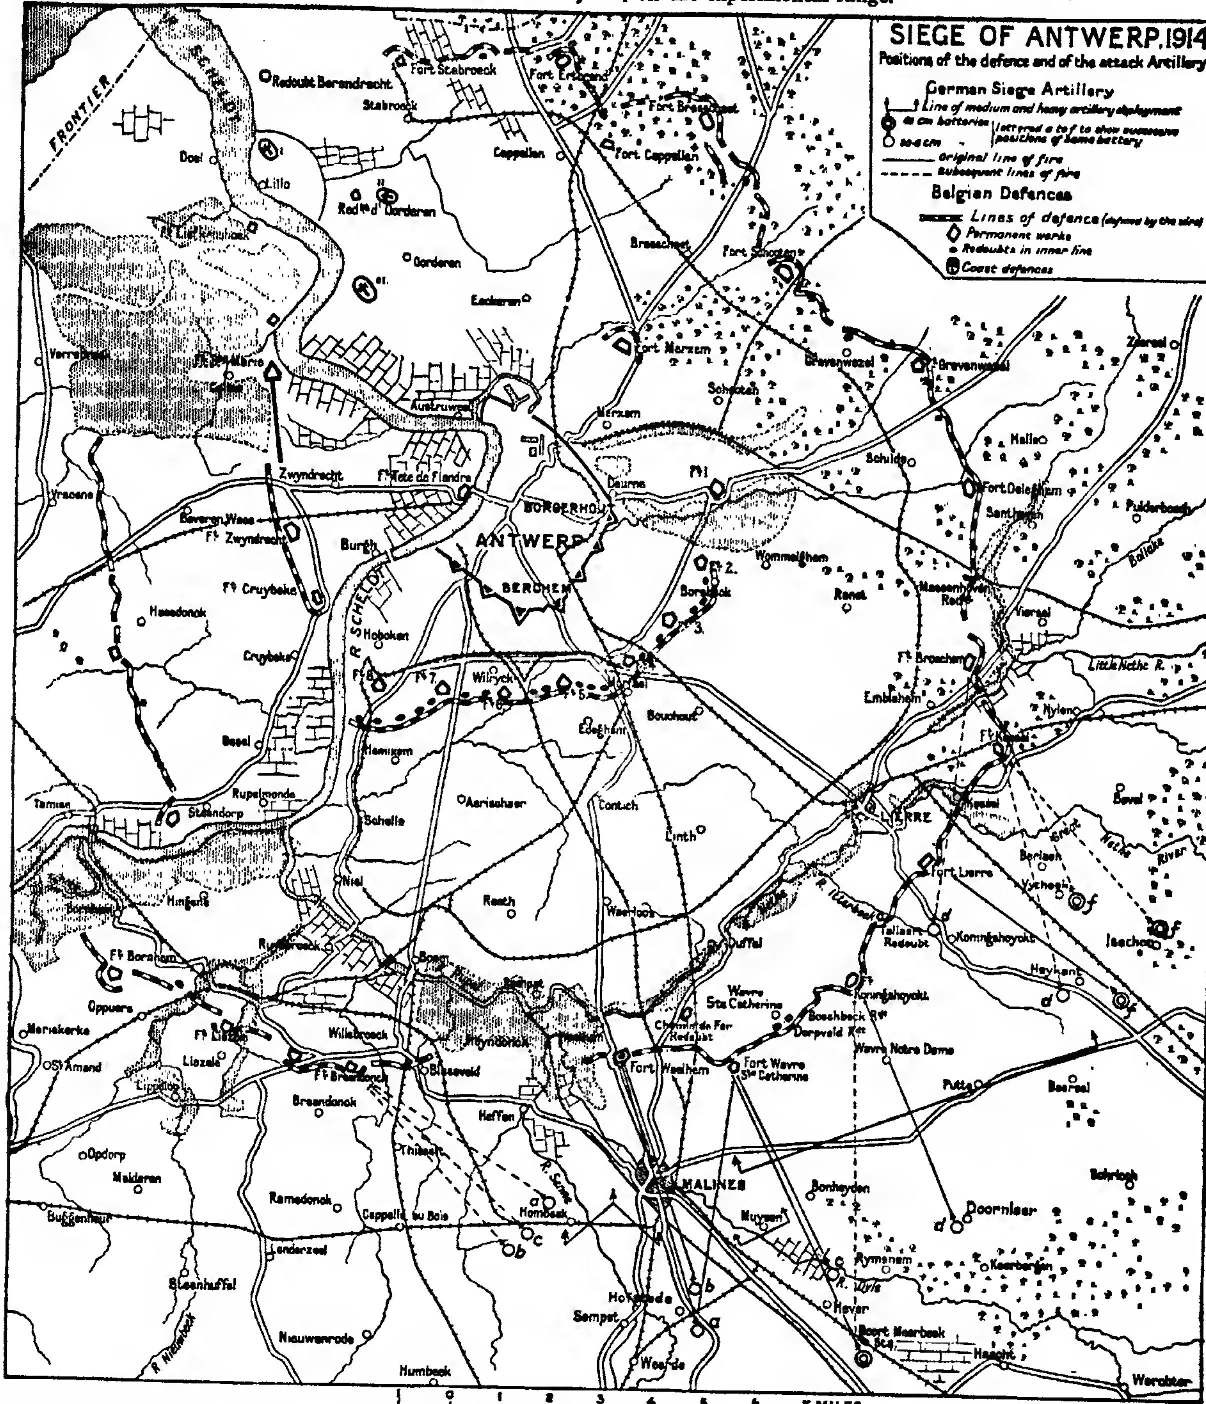
[1] Twenty-eight cm. howitzers were used by the Japanese at Port Arthur 1904–5. The first German model of 30·5-cm. siege howitzer was designed as early as 1898. (C. F. A.)

[2] Its 38-kgm. shell was powder-filled. An order for 8,000 H.E. shells had been placed in Germany in 1912, but the firm concerned failed to deliver them.

[1] The artillery of the field army of course excluded.

[2] Till Sept. 8 Beseler remained under command of I. Army. From Sept. 8 to Sept. 10 his force was under the VII. Army headquarters. Finally on Sept. 17 the force was designated "Armeegruppe Beseler." (C. F. A.)

from Maubeuge to the region N. of Brussels. The powerful *matériel* which had laid in ruins the forts of Liége, Namur and Maubeuge in succession was in fact now on its way to Antwerp. Soon it was established in position in all the region between the Dyle and the Grande Nethe, from Boortmeerbeek to Heyst-op-den-Berg.[1] The heaviest ordnance, 30·5-cm. and 42-cm. howitzers, had not only demolishing but also ranging power. They could install themselves in perfect safety beyond the extreme range of the Belgian guns, and regulate their fire as if on the experimental range.



[1] The total artillery strength of the Germans before Antwerp was:

Field Artillery	F. Gun	25 batteries	150 pieces
	F. How.	6 "	36 "
	Total		186 pieces
Heavy Field and Siege Artillery Guns	10 cm.	6 batteries	24 pieces
	13 cm.	4 "	16 "
	15 cm.	2 "	8 "
	Long guns		48 pieces
Howitzers	15 cm.	18 batteries	72 pieces
	21 cm.	12 "	48 "
	Howitzers		120 pieces
Super-heavy Howitzers			
German and Austrian	30·5 cm.	4 batteries	9 pieces
German	42 cm.	2 "	4 "
			13 pieces

(C. F. A.)

On Sept. 27 the German operations assumed the character of the beginning of a siege. The town of Malines received a violent bombardment and was evacuated. The artillery deployment of the attack was completed, and fire opened on the 28th.

The Army Group Beseler comprised at that time the 37th Landwehr Bde. between Alost and Termonde, where it had served in flank guard since Sept. 14; the 4th Ersatz Div. (arrived from Lorraine on the 26–27) between Termonde and the Willebroeck canal; the Marine Div. between this canal and the Dyle about Malines; the III. Res. Corps from the Dyle to the Antwerp-Aerschot railway (5th R. Div. on left, 6th R. Div. on right), and the 26th Landwehr Bde. N. of Aerschot, with a group furnished by the III. Res. C. further to the right front at Westerloo.

The specialist troops, besides the medium and heavy artillery already alluded to, were two regiments and some additional units of pioneers, four railway companies, three kite balloons and a flight of aeroplanes, a survey section and two searchlight sections. General von Beseler himself was an engineer general and had been inspector-general of pioneers.

Field-Marshal von der Goltz, Governor-General of Occupied Belgium, had at his disposal some brigades, of which the 1st Reserve Ersatz Bde. and the 1st Bavarian Landwehr Bde. joined the Beseler Group directly, while the 41st Landwehr Bde. watched the left rear between Alost and Ninove, and the 38th Landwehr Bde. the right front near Beverloo Camp.

Siege Operations.—It at once became clear that the attack was being concentrated on the south front of the fortress. The attack project elaborated by the Germans in peace-time had made the east front the objective. On the other hand, an attack against the west front would have had the advantage of isolating the Belgians from Allied support. But von Beseler had not the necessary forces to prosecute a siege on this side while still covering the communications through Brussels against a sortie. In spite, therefore, of the fact that the Nethe and its inundations lay behind the fort line, he had decided to attack the south front.[1] Trusting in the thrice-proved powers of his weapons of attack, he set out to spare his infantry, to crush and throw into confusion the lines of defence by gunfire, ruin the mechanism of the organs of defence in the forts by methodic hammering, controlled by aircraft, destroy the guns in their cupolas and the garrison in their shelters—more certainly than would have been possible if they had been dispersed—before giving them a chance of fighting. These results attained, he would then cautiously advance his infantry and gain a footing in the shattered forts and pulverized lines of defence.

The Belgian troops were thus faced with the prospect of waiting stoically and in obscurity, without hope of riposte, under the fracas of a cyclopean bombardment, till the moment when they should be blown up or crushed at their posts.

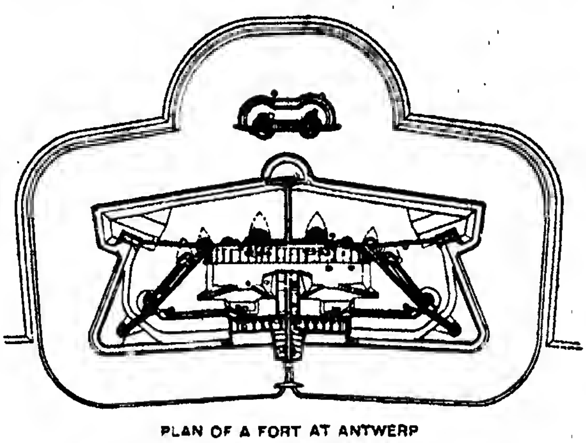
Under such conditions they could not hold out very long. It was essentially a question of the number of mortars and the quantity of munitions possessed by the assailant and of the destructive power of each separate projectile. Actually this unequal struggle lasted 10 days and nights without truce, and this time was infinitely precious in retarding the moment when the Germans—rid at last of the menace of the Belgian army on their right rear—could freely and with better chances renew their great effort to reach and envelop the left flank of the Franco-British armies.

On Sept. 27 the Belgian field army was distributed on the most dangerous sectors as follows: The 1st and 2nd Divs. between the Senne and the Nethe from Willebroeck to Lierre with the 5th Div. in reserve N. of the Nethe; the 6th and 3rd Divs. between the Senne and the Scheldt; the 4th Div. at Termonde and the cavalry division about Alost-Wetteren to cover the communication between Antwerp and the sea.

On the morning of the 28th the German cannonade was let loose along the whole front between Termonde and Lierre. Under cover of this the infantry got into contact with the outposts of the fortress. The Belgian guns replied with vigour.

[1] His request for additional forces wherewith simultaneously to operate west of the Scheldt was refused by headquarters.

Between the Scheldt and the Senne Belgian detachments energetically repulsed their assailants (4th Ers. Div. and Mar. Div.), notably on the outskirts of Blaesveld (S.E. of Fort Breendonck). But E. of the Senne towards noon, the super-heavy artillery came into action and began by engaging Forts Waelhem and Wavre Ste. Catherine.[2] At Fort Wavre Ste. Catherine the first 42-cm. shell pierced a concrete vault 2½ metres thick. At 1 P.M. the gallery of the gorge front was demolished. Other vaults, including those of the fire-control room, suffered the same fate; a cupola was jammed, and the left traditore battery crumbled into the ditch. The other forts suffered less. The firing, after a pause in the evening, continued with intensity all through the night on most of the forts. On the 29th, W. of the Senne renewed attacks, especially heavy about Blaesfeld, were repulsed. Between the Senne and the Nethe the cannonade was even more violent than on the previous day, both the trenches in the intervals and the permanent works being engaged. From 5 A.M. Fort Wavre Ste. Catherine (which in fact was the point selected by von Beseler for the break-through) received 42-cm. projectiles at regular intervals of seven minutes, not counting those of 21 and 30·5 cm.



PLAN OF A FORT AT ANTWERP
SHOWING ALL HITS OF CALIBRES ABOVE 21 CM.
●—HITS

It is difficult to imagine the terrible situation of a garrison subjected to such a bombardment. The arrival of a 42-cm. projectile is announced by a deafening roar. When it bursts in the masonry the whole mass of the fort shakes violently and seems to sink in the earth and to oscillate back to its original level. The blast throws men against the walls. Poisonous fumes and clouds of cement dust cause violent sickness and sometimes suffocation. Under such conditions, and in close confinement, it is easy to see why the men lost not only their powers of action but even, it seemed, their reason.

The men's quarters were destroyed, fires broke out, the air became unbreathable and the greater part of the garrison took refuge on the berm of the ditch. A 42-cm. projectile went through the dome of one 15-cm. cupola, exploded, and tossed the voussoirs to a distance of about 30 feet. The second 15-cm. cupola was put out of action by a 30·5. The other cupolas were either destroyed by being laid bare or made inaccessible by the obstruction of their galleries. One magazine was hit by a shell and blew up. The double caponier of the capital was completely ruined.

By 11 A.M. the fort had all its guns out of action and all means of defence destroyed. The survivors of the garrison were authorized to evacuate it as fire rendered it untenable. Forts

[2] The artillery of medium and heavy calibre was deployed mostly along the Malines–Heyst-op-den-Berg road, the rest behind Malines, at ranges of 3,500 to 7,000 yd. from the two first and 5,000 to 9,000 from the two last-named forts. Of the super-heavy artillery two 30·5-cm. batteries (range 9,500 and 10,500 yd.) engaged Fort Waelhem and Chemin de Fer or Duffel redoubt; a 30·5 battery (8,500 yd.) and a 42-cm. battery (11,300 yd.) attacked Fort Wavre Ste. Catherine; an Austrian 30·5-battery (range 8,800 yd.) Fort Koningshoyckt, and a 42-cm. battery (range 9,000 yd.) Fort Lierre. All these were two-gun batteries except the Austrian, which had four. The ranges here given are approximate. For positions see map.

(C. F. A.)

Waelhem and Koningshoyckt, less heavily bombarded, continued to reply vigorously.

On the 30th the situation grew worse. The 1st Div. deployed between the Heyndonck inundation and Fort Wavre Ste. Catherine was worn out by three days of bombardment and had to abandon its ruined entrenchments and transfer the defence to the N. bank of the Nethe, leaving Fort Waelhem to defend itself in isolation. The right of the 2nd Div., affected by the retreat of neighbouring troops, and itself heavily engaged, gave way at one time.

The German infantry had not yet attacked[1] at any point, but all the works had suffered terribly except Fort Lierre. The artillery both of the forts and of the intervals maintained the struggle all day against the German gunners. Between the Senne and the Scheldt two powerful attacks on Blaesveld and on the sector of the 6th Div. were repulsed.

The Germans, expecting that by this time Fort Waelhem, Fort Wavre Ste. Catherine, and the defences to the N.E. would be "ripe for storming," had fixed Oct. 1 as the day for their break-through. Accordingly the Marine Div. was to attack Fort Waelhem, the trenches adjacent, and Chemin de Fer redoubt, and the 5th Res. Div. to storm Fort Wavre Ste. Catherine and the Dorpveld redoubt. The attack of the Marine Div. failed to reach Fort Waelhem (the Belgian 1st Div. having largely reoccupied the trenches evacuated the day before), but its right captured Elsestraat, and after a sharp initial repulse the 5th Res. Div. reached its objectives, while the Belgian 2nd Div., after prolonged resistance under bombardment, began retreating to the Nethe.

Meantime the works of the Senne-Nethe sector had been subjected to a final and terrible hammering. Fort Waelhem had been mortally wounded. A 30·5 projectile blew up a magazine killing or grievously burning a hundred men who were sheltering in the adjacent postern. But the fort still claimed to be in a condition to fire, and, in fact, the assault on this fort was a definite failure, as also was an attempt made in the night of the 1st–2nd. Fort Wavre Ste. Catherine was carried by the German infantry in the evening of the 1st.[2]

The Dorpveld redoubt had been bombarded intermittently on the 29th and 30th, and on Oct. 1 from 8:30 A.M. Towards 5 P.M. an assault was delivered. The only 7·5-cm. cupola being out of action, the survivors of the garrison held the rampart for half an hour, then abandoned the firing crest and took refuge underground; a company of the enemy's infantry installed itself in the mass of the cupola and the craters of the earthwork, but the garrison kept up rifle-fire from the barrack windows.

The commandant of the work managed to get a friendly field battery outside to sweep with shrapnel the enemy installed over his head; reciprocally, his own traditore battery came into action about 11:30 P.M. to defend the interval. On the 2nd, towards 3:30 A.M., on their side, the Germans attacked the roof of the fort by mining, and the concrete, which was of poor quality, began to yield in the right-hand part of the work. From this point the artillerymen could be of no use, and they were withdrawn under cover of darkness one by one, under the fire of a German machine-gun on the redoubt. Towards 5 A.M. a second mine, still more powerful, breached the vaulting, and the enemy took possession of the deserted floor. After defending for some time an improvised barricade which limited the assailants' progress, the commandant and 12 men, the sole survivors, were forced to surrender about 6 A.M. Fort Koningshoyckt, though violently attacked by 30·5's, took a vigorous part in the evening in repulsing the attack on the intervals.[3] Fort Lierre, after six hours' uninterrupted bombardment from the 42's, repulsed an attempted assault early in the evening. The same night (1st–2nd) the Germans tried in vain to pierce the interval between Fort Lierre and the Tallaert redoubt.[4]

Between the Scheldt and the Senne the German infantry made no move on this day. The artillery, however, kept up a continuous hammering on the front of the Belgian 3rd and 5th Divs., and especially on Fort Breendonck.

On Oct. 2 the Belgian 1st and 2nd Divs. crossed the Nethe and pushed forward to regain the intervals lost during the night, but were checked by violent artillery fire, and King Albert therefore decided to transfer the defence to the north of the Nethe, and had all crossings destroyed.

The evening was marked by the death-struggle of Fort Waelhem. Here the recent strengthening of the structure had consisted chiefly in overlaying one metre of concrete on the old brickwork of 1881, and, according to the Germans, the 21-cm. shell falling in large numbers on the fort contributed as much to its ruin as the 30·5's of which calibre the fort received 30 effective hits out of 556 fired. The Tallaert redoubt and Fort Koningshoyckt were evacuated, being in ruins, the first-named owing to the explosion of a magazine, the second owing to the havoc of the shells. On the fall of Fort Wavre Ste. Catherine the 42-cm. battery hitherto engaged against that fort was turned on to Fort Koningshoyckt, superposing its effect on that of four Austrian 30·5's. At Fort Lierre, after the fruitless attack of the previous day, the German artillery opened fire at 7:30 A.M. and battered successively all the organs of the fort. Several aeroplanes aided in directing the fire, and here the single 42-cm. battery engaged obtained a higher percentage of hits than elsewhere (32 out of 175 rounds). All the cupolas where put out of action, and all the chambers had to be evacuated in turn. By 5:15 P.M. the fort was practically destroyed and shortly afterwards it was evacuated. The Germans did not occupy it till next day.

On the 3rd the small Duffel (Chemin de Fer) fort, armed with six 5·7-cm. cupolas, on which the German artillerymen no doubt disdained to waste a 42,[5] held the enemy engaged the whole day until its munitions were exhausted. The commandant then blew up his defences and brought back his gunners and his wounded to the N. bank of the Nethe. The German infantry of the Marine Div., which advanced during the day and the night, occupied the ruined redoubt early on Oct. 4.

The Belgian troops now began to be seriously disheartened. The forts, in which their confidence—though misplaced—had been supreme, had in a few days been shattered under their eyes by the blows of a monstrous artillery, and they knew that their field artillery had nothing[6] but its own brave audacity with which to carry on the struggle. All its efforts were concentrated on thwarting the enemy's active preparations for crossing the Nethe, where the infantry hastily erected new lines of defence.

The events of these days had left no illusions as to the fate in store for Antwerp's fortified positions. It had been proved that the 42-cm. or even the 30·5-cm. shell would pierce a non-reinforced concrete vault of 2½ meters or the 24-cm. (9½ in.) chrome-nickel-steel domes of the cupolas. Once fire had been opened on a fort it was a question not of days but of hours to put it completely out of action. This being so, the idea that the entrenched camp of Antwerp could constitute a definite place of refuge for the army and the Government had to be abandoned once for all, on pain of involving the army in the surrender of the fortress. But another and a far more serious

[1] In its methodical advance it had reached the line of the Vrouwenvliet (Marine Div.); a line 700 yd. from Fort Wavre Ste. Catherine (5th Res. Div.); Wavre Notre Dame and Koningshoyckt (6th Res. Div.); Berlaer (37th Lw. Bde.). On the 30th the Germans were very anxious about their right flank, owing to Belgian activity in the region E. of Fort Kessel. (C. F. A.)

[2] According to the German account the light flanking guns were still in action when the fort was stormed. Authority had however been given to the commandant (see above) to evacuate it. The fort received 44 hits (out of 500 rounds fired) from super-heavy calibres. Observation difficulties, due to the country, seem to have made control of fire unsatisfactory. (C. F. A.)

[3] According to the German account, the defenders were even able to counter-attack on this part of the line.

[4] Tschischwitz says that the existence of the Tallaert redoubt came as a surprise to the Germans. (C. F. A.)

[5] After the ruin of Fort Waelhem, however, a 30·5-cm. battery was switched on to the redoubt, against which it fired 137 rounds. (C. F. A.)

[6] Ammunition supply had become a matter of anxiety by the evening of Oct. 3.

menace threatened the army more and more as the days went on. For a fortnight past the "Race to the Sea" had been in progress in France. Each side, hoping to envelop the outer flank of the other or seeking to protect its own flank from the same fate, was being led by a series of parallel and practically synchronous efforts to displace the centre of gravity and the decisive point of the campaign towards the sea. Thus by the end of Sept. the battle-front had been extended from the Oise to Arras and Béthune, and fresh German masses were traversing Belgium in a westerly direction.

The real peril to which the Belgian army was exposed lay in the possible failure of the Allied left to gain on the enemy's right and join up with the Belgians on the Scheldt. Yet this junction must be effected at all costs, even if the fortress had to be abandoned in order to get into contact with the Allies.

The King was strongly in favour, however, of holding the fortress until the last extremity, in order to hind the troops and material now concentrated hefore it, and also to gain the maximum of time for the formation of a Franco-British-Belgian front on the Scheldt and the Dendre—the natural rampart of the coast, the Straits and England. To prevent the Germans from reaching the coast would be an inestimahle service rendered to the Allies, and the King was determined not to relinquish the idea save in the last resort. Every day gained at Antwerp meant a French port saved—to-day Boulogne, the next day Calais, the next Dunkirk—and the withholding from the Germans of the Straits of Dover, the most important maritime artery in the world.

Mr. Winston Churchill, then First Lord of the Admiralty, fully realized the capital rôle which the fortress might play in the war. With great foresight and initiative he had drawn the attention of the British War Office to the strategic importance of Antwerp in the beginning of September. In the first days of Oct. he came in person to the besieged fortress to take stock of the situation. The Belgian Command gave him a frank statement of its intentions, and King Albert informed him personally of the rôle he proposed for the Belgian army on the extreme left wing of the Allied front. Being entirely in agreement, Mr. Churchill returned in all haste to London to push forward the immediate dispatch of all the troops the French and English Governments could spare to Antwerp and Ghent. It was urgently necessary (1) to guarantee the effective union of the Belgian army with the general Allied front and (2) to bring about this union on a level with Antwerp, or, failing this, on a line as far east as possible with its left resting on the Dutch frontier or the coast, so that the enemy could in no case seize and envelop the Allies' extreme left wing.

Given the double aim which the King had in view, that of holding Antwerp as long as possible and not allowing himself under any circumstances to he cut off from the Allies, there was no time to he lost in transferring the main base of supplies from Antwerp to Ostend, whence the army could carry out its subsequent operations in concert with the Allies. The transport of materials and supplies and the evacuation of the manufacture and storage establishments, of the wounded, the prisoners and the recruits therefore commenced on Oct. 1. Although the only through railway connexion between the E. and W. hanks of the Scheldt was that hy way of Willebroeck, Puers and Tamise railway hridge, within range of the enemy's guns, the trains followed one another night after night, with all lights out, until Oct. 7 without attracting attention. West of the Scheldt the evacuation transports and convoys were protected by the 4th Div. round Termonde, and the Cavalry Div. round Wetteren.[1]

British Assistance.—The immediate result of Mr. Churchill's personal intervention was the arrival at Antwerp, on the evening of Oct. 3, of a brigade of 2,000 men of the British Royal Naval Division. The apparition, at dawn on the 4th, of these the first Allies the Belgian soldiers had set eyes on during the two months of the war—aroused a wholesome enthusiasm among the dispirited defence troops. Unhappily, this assistance could be no more than a moral stimulus for a fresh burst of energy.

Meanwhile, the German infantry E. of the Senne advanced steadily as near to the Nethe line as the Belgian fire permitted, while the medium and heavy artillery moved up to new positions, and the super-heavy batteries, freed by the fall of all works between Waelhem and Fort Lierre inclusive, got into place to attack Fort Breendonck on the left flank and Fort Kessel on the right—three German 30·5 batteries W. of Hombeek engaging the former, and the Austrian 30·5's at Heykant and one 42-cm. battery[2] at Isschot the latter. On the 4th the six pieces concentrated upon Fort Kessel at ranges of 9,000–9,300 yd. quickly finished their work, the place heing ruined and evacuated just before midday. It was not until the 6th, however, that fire was seriously directed upon Fort Breendonck.

Gen. von Bescler's original scheme was that each unit on the III. Res. Corps front should strive on its own account and at its own time to obtain a foothold beyond the Nethe, while the Marine Div. remained echeloned back on the left, and the 26th Landwehr Bde. advanced on the right as close to Fort Kessel as possible. The fire directed upon the half-exposed left of the 5th Res. Div., however, soon made it necessary that the right of the Marine Div. should also attempt to advance. In this it was unsuccessful, and during the 4th the whole of the 5th Res. Div. and part of the 6th could do no more than approach the water-line.

On the right of the 6th Res. Div., on the contrary, a bold advance carried the Germans into Lierre, and there began in that town a prolonged and fierce struggle, the British Marine Bde. deployed along the Little Nethe and the 5th Belgian Div. on the Nethe between Lierre (excl.) and Hit Ven (excl.) completely holding up both the right of the 6th Res. Div. and those troops of the 26th Landwehr Bde. which, on the fall of Fort Kessel, had pushed up to Klosterheyde.

On the evening of Oct. 5 the German force in Lierre was still pinned down by the fire of the Marine Bde. Further south, under cover of a very heavy bomhardment, they had succeeded in crossing the river, but were held a short distance beyond it, along the road from Hit Ven to Lierre, with only precarious communications hehind them.

On Oct. 6 at dawn the 5th Div. tried, by a general counter-attack, to throw the enemy hack to the S. of the Nethe. But with the whole mass of the German artillery free to cover its infantry the counter-attack was foredoomed. The Belgian guns vigorously supported it, and a determined attack near Ringenhof was for a moment successful and produced a crisis in the German line. But no more could he done. The assistance of Fort Broechem was at an end, since on this day it was taken under fire by the 42-cms. and the Austrian 30·5-cms. which had ruined Fort Kessel and then advanced to their third positions at Vythoek and Koningshoyckt respectively. More and more German infantry was, hy one means or another, got across the Nethe, and the débris of the 1st, 2nd and 5th Divs. and the English Marine Bde. fell back little by little in the afternoon

[1] A first attempt on Termonde had been made on Sept. 26 by the 27th Landwehr Bde. advancing from Alost down the left bank of the Dendre. Not only had this been hung up at Gyseghem, half-way, but Alost itself in its absence had fallen to an attack by Belgian forces from Wetteren. The 27th and 28th were taken up in recapturing Alost, which was thenceforward held, though the garrison was "constantly and severely worried by cavalry, cyclists, armoured cars and armoured trains" in the words of the German account. A detachment of the brigade was sent up to watch the S. side of Termonde, and one from the 4th Ers. Div. was similarly posted (not without fighting) at Baesrode. The whole force on the left was placed under the 4th Ers. Div. staff, but until the arrival of further troops from the governor-general's forces (1st Res. Ers. Bde.) nothing could be done. On Oct. 4 the arrival of these troops, behind which the 1st Bav. Lw. Bde. was also coming up, released the 37th Lw. Bde. from Alost, and an advance was made by this brigade to Schoonarde on the Scheldt, with a view to forcing the passage there and reaching Termonde from the rear. On the 4th, 5th and 6th, however, attempts to do so were repulsed by the defenders, and throughout the critical days the Germans were unable to interfere with movements in the Lokeren region. (C. F. A.)

[2] The 42-cm. battery which had attacked Forts Wavre Ste. Catherine and Koningshoyckt was a railway battery, and had to remain inactive for the time being. (C. F. A.)

to the line Contich-Bouchout, where civilian labourers and recruits had dug some rough trenches.[1]

Meanwhile, along the Scheldt, the enemy's attitude was becoming more and more aggressive in the efforts to gain the crossings at Baesrode, Termonde and Schoonaerde. The situation of the Belgian 4th Div., on a front of 18 m., began to be serious. There lay the gravest danger which threatened the Belgian army—that of being invested in the fortress. The 6th Div., which with the 3rd Div. still held the fort line between the Willebroeck canal and the Scheldt, now received orders to cross the Scheldt at Tamise to reinforce the 4th Div. and safeguard the army's communication with the west.

Withdrawal of the Belgian Field Army.—The defence troops were becoming extremely fatigued, the bravest among them being daunted by the uninterrupted bombardment and the persistent feeling of helplessness in the face of the weapons which had pulverized forts and lines of defence in succession. Soon the enemy would be bringing up his batteries to bombard the city itself. If it had taken only a week to reduce the principal line of resistance constituted by the modern forts on the S. of the Nethe, still less would suffice to break up the old forts of the inner line. The fortress could now offer no prolonged resistance. Moreover, all hope of linking the Antwerp front with that of the Franco-British armies had to be abandoned. Two new English naval brigades, recently formed, had arrived in the fortress on the 5th, bringing the effective of the Royal Naval Div. up to 10,000 men; a French naval brigade had been moved from Dunkirk to Ghent and the British 7th Div. and 3rd Cavalry Div. under Gen. Rawlinson had landed at Zeebrugge and Ostend. Had these troops arrived a few days earlier a combined operation against the left wing of the besieging force might have changed the face of the war. But it was too late. As Mr. Churchill said:—" A week earlier, the result would have been a certainty . . . a little later 200,000 men could not have carried the operation through."

On the one hand, the Germans were threatening the line of retreat through Termonde. On the other, liaison with the Allies was compromised, for the German right wing in France was now hardly more than 30 m. from the sea, whereas the distance from the Nethe to Nieuport was 85 miles. This being so, one consideration now dominated all others—the Belgian army must avoid being surrounded. On the evening of Oct. 6 the King decided to separate the lot of the main body of the army from that of the fortress, and gave orders to cross to the left bank of the Scheldt during the night of the 6th–7th. The troops were then to continue their march westward. It was high time, for, on the 7th, the Scheldt was forced at Schoonaerde, the Germans making every effort to throw back the 4th Div. on Lokeren.

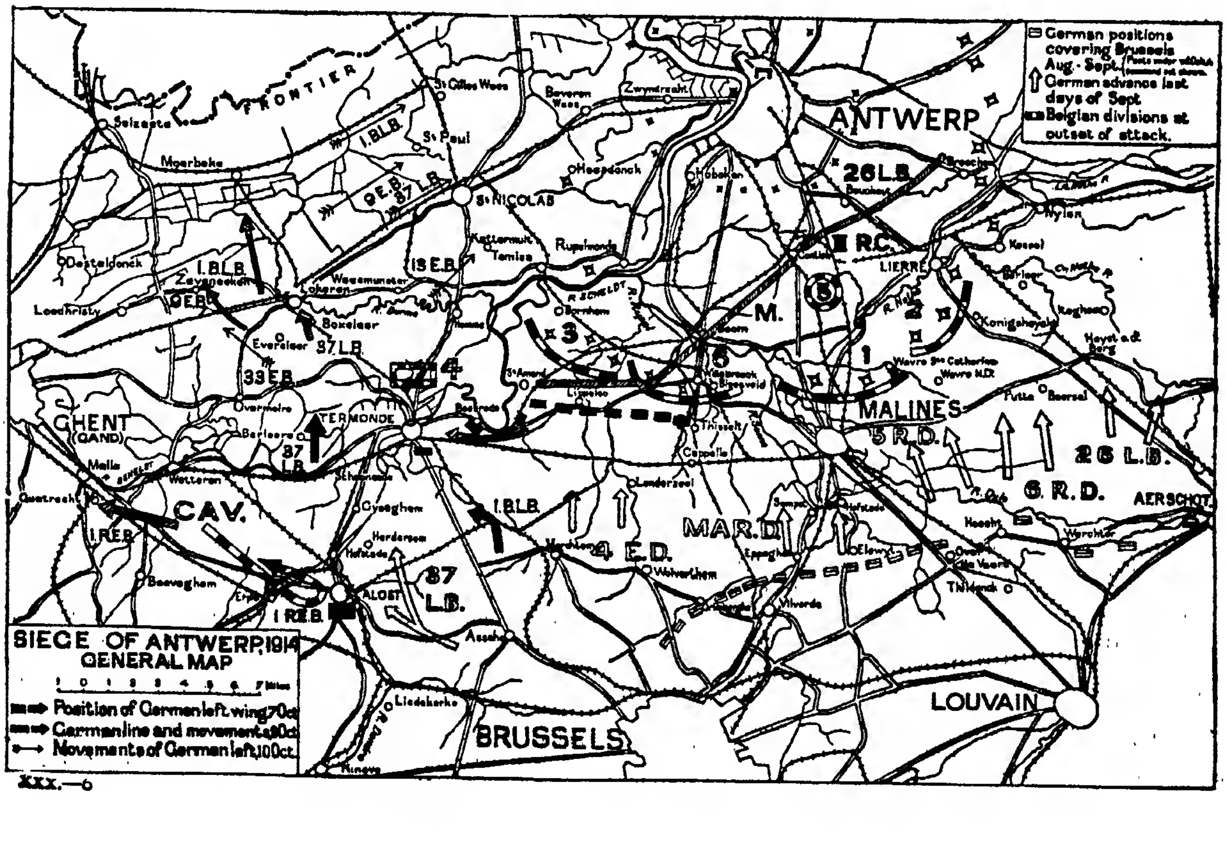
The fortress was still to be defended to the utmost by Lt.-Gen. Deguise, the governor. The garrison proper (personnel of the forts and fortress troops) with the 2nd Div. and the British Naval Div., some 50,000 men, were more than enough to do what could be done with the remains of the fortress.

The Final Resistance.—On the 6th Fort Broechem, battered all day by four 30·5's and two 42-cms., had been put out of action and dismantled. The improvised line Aertselaer-Contich-Bouchout was merely a row of light shelter-trenches, lacking in depth and with both flanks in the air. General Deguise considered it too risky to commit his forces, very inferior as they were, to a determined defence of this exposed position.[2] He therefore placed the 2nd Belgian Div. and the English Div. on the line of forts No. 1 to No. 8. These two divisions stoically endured there the usual bombardment throughout the days of the 7th and 8th. Meanwhile the main body of the Belgian army

[1] The German official account criticizes the inactivity of Gen. Paris in not seizing the opportunity offered by the success at Ringenhof. Whether this criticism be well founded or not it shews that the position at that moment was regarded by the German command as critical.

[2] On the night of the 6th the German line ran from a point S. of Fort Broechem, along the Little Nethe and in advance of the Nethe, to a point about 1 m. W. of Duffel Station. The Marine Div. was still short of the general alignment, not having crossed the river. On its left, the 4th Ersatz Div. faced the line of the south-western forts, of which Fort Breendonck was beginning to be subjected to bombardment. The left of the 4th Ersatz Div. was at St. Amand and Baesrode on the Scheldt, in touch with the forces operating at and above Termonde. On the extreme right, detachments were advancing in the direction of Massenhoven redoubt and Santhoven.

(C. F. A.)



was moving between the Scheldt and the Dutch frontier, seeking contact with Rawlinson's force and the French Naval Bde. which were collecting towards Ghent.

In the afternoon of the 7th, under instructions from O.H.L., Gen. von Beseler informed the governor of his decision to bombard the city of Antwerp, commencing at midnight, in default of previous capitulation. This attempt at intimidation had not the smallest effect upon either Gen. Deguise or on the Communal Council which, convoked by the governor, declared itself to be "willing to accept the consequences of prolonging the defence to its extreme limits," and assured him, moreover, that it never would try to influence the decision of the military authorities responsible for such defence.

The bombardment began at midnight.[1] It was directed especially on the gates of the enceinte. Certain quarters of the town were attacked by long-range guns. On the same night (7th–8th) part of the III. Res. Corps pushed its patrols up to the fort line of defence.

On the 8th, Gen. Paris, the English general, and Lt.-Gen. Dassin, commanding the Belgian 2nd Div., came to the conclusion that resistance to a determined attack on the following day would be hopeless. On hearing this and also that Gen. Paris, after telephonic communication with the British Admiralty, had received orders to bring away the Naval Div., Gen. Deguise at 5:30 P.M. gave up the idea of holding the fort line of defence any longer, and decided to take advantage of the night to withdraw all the troops occupying it to the left bank of the Scheldt.

The orders were:—

(1) The British Naval Div. to cross in the night and entrain at St. Gilles Waes for Ostend.

(2) The 2nd Belgian Div. to accompany the British Div., covering its entrainment at St. Gilles Waes against the German troops reported near Lokeren (see below), then to march westward and try to rejoin the rest of the Belgian army.

(3) The forts still intact to defend themselves individually to the utmost.

(4) The enceinte to be handed over to the Germans when they appeared before it, in order to save the city from unnecessary damage.

(5) A force of some 20,000 men of the garrison troops, under Gen. Deguise himself, to hold out as long as possible in the entrenched camp formed by the Scheldt and the forts of the left bank.

These movements took place in the night of the 8th–9th without being disturbed by the Germans (who had no suspicion of them), but not without a good deal of confusion. Meanwhile the bombardment of the city continued.

On the 7th the Germans had succeeded in forcing the passage of the Scheldt at Schoonaerde. The advance was pushed to within 2 m. of Lokeren, where sharp resistance was again met. The Belgian army was in fact streaming past the front of this small force in several columns; neither side, however, was in a position to take the initiative of an encounter battle, the Germans owing to the tactical, the Belgians owing to the strategical risks that this action would have involved.

Next day the Belgian divisions, though the enemy did not know it, were past the reach of attack and in touch with the French and British forces at and north of Ghent, leaving no baggage or stragglers to be picked up, since all impedimenta had been removed in the transfer of base to Ostend several days earlier.

On the 9th, therefore, the three German brigades, now followed by the rest of the 4th Ersatz Div., struck a blow in the air, while the 1st Res. Ers. Bde. from Alost advanced on Ghent, and at Melle became involved in a very heavy fight with the French Naval Bde. and some Belgian batteries (Oct. 9 and 10). On the 10th, wheeling inwards to invest the fortress, and thus turning their backs to the Belgian field army, the five German brigades N. of the Scheldt pushed on to the line St. Gilles Waes-St. Nicolas, Kettermuit. But instead of the expected main body of the Belgians they only encountered the 2nd Belgian Div., which passed under fire of their guns at Moerbeke westward and the two last battalions of the British Naval Div., which were caught at St. Gilles Waes and forced over the Dutch frontier.

Thus did the greater part of the prey which the Germans counted on capturing at Antwerp escape them.

Meanwhile Gen. Deguise was preparing to defend the entrenched camp on the left bank of the Scheldt. But his remaining troops were of mediocre quality. The men of the fortress battalions were old, their officers few—hardly one per company—and nearly all either reserve officers or newly commissioned. The N.C.Os. were scarce and did not know their men. In fact, Gen. Deguise had 20,000 men in uniform rather than 20,000 combatants. On troops such as these the fury of the bombardment naturally had produced a great effect, and the departure of all field troops, and that of the English whom they had welcomed so hopefully, led them to look upon themselves as so many units written off. During the whole of the 8th and 9th their lines were crossed by crowds of civilians who, carting their families and their furniture and driving their live stock in front of them, filled all the roads and routes leading westward, repeating as they went the stories, a hundred times magnified, of Visé and Louvain, of Dinant and Aerschot.

The spectacle of this deplorable exodus completed the depression of the soldiers. It was no longer possible to expect this almost shepherdless flock of men at bay to defend themselves in open trenches when they had seen armour and concrete ruined in a few hours.

On the evening of the 9th Gen. Deguise, knowing that the Germans were near Lokeren and believing, through an erroneous report, that they had also crossed the river at Antwerp itself, became convinced that no further organized resistance was possible. Officers and units were allowed to leave the fortress at will and were to attempt to rejoin the field army. Many acted upon this and some succeeded, the rest taking refuge in Holland. On the 10th the general sent a flag of truce to Gen. von Beseler to enquire the conditions of surrender. But meantime the civil authorities, seeing the city to be empty of troops, had acted on their own account. The situation was grave. At about twenty points fires had been started by the bombardment. The waterworks at Waelhem on the Rupel having been in German hands for a week, the firemen could not undertake to master the flames in the fire areas. With a sudden violent wind the whole city might be set ablaze.

To save the city from a disaster, which could be of no advantage from a military point of view, the leading townsmen had sent a deputation to Gen. von Beseler to obtain a cessation of the bombardment, and on the afternoon of the 9th an agreement was signed suspending the bombardment on condition of the surrender of all the works of the fortress the following day at noon. Gen. Deguise had no choice but to ratify this agreement.

Deep as was the impression made upon the world by the fall of Antwerp, the material strategic gain to the Germans was far less than had been anticipated. Although in military stores and economic resources their booty was considerable, not only had the whole of the Belgian field army made good its escape, but not even the fortress troops were left to adorn the German triumph. As to the works which had not been attacked, they were empty and in most cases rendered useless by their commandants.

Antwerp—Port Arthur—Verdun.—The rapid fall of Antwerp in 1914 may seem astonishing when compared with the resistance of Port Arthur in 1904 and that of Verdun in 1916. It is necessary, however, both in appreciating the resistance of the Belgian fortress and in deducing technical lessons from the siege, to compare the conditions of the three cases in some detail.

Although Port Arthur possessed no cupolas and several of its forts were unfinished, yet the Russians had six months' leisure to prepare, not a line, but a zone of defence 3 m. deep, in which forts, trenches and redoubts formed a tangled system, cleverly applied to very difficult ground. Dug out of hard rock, these entrenchments offered an exceptionally good resistance to the engines of destruction. The artillery of the defence was ample and well distributed in the intervals. Finally, the Japanese

[1] It was opened by a battery of 5·9 shielded guns, E. of Lierre, 16,500 yd. from the nearest point of the enceinte. Later 13-cm. batteries were also employed. (C. F. A.)

siege material included at first no calibres above 15 cm. It was only after two months of the attack that 28-cm. mortars were brought up. Of these the Japanese brought 18 pieces into action, and their projectiles broke through the 1-metre concrete of the permanent forts. But even so the artillery played a secondary rôle. Under these conditions the *moral* of the defence was bound to be excellent, and the fortress was taken by Nogi only after sapping, mining and very heavy sacrifice of life.

At Verdun the Germans used the same calibres and somewhat the same methods of attack as at Antwerp. The bombardment was to annihilate the defence, the infantry to reap the results of the bombardment, and in fact the progress made during the first days was considerable. If they failed in their undertaking it was because the French promptly brought up a great quantity of artillery and established a regular system of reliefs for the troops in line[1]; because the broken ground on the banks of the Meuse was favourable to the defence; because the forts had been strengthened by reinforced concrete (some of them, notably Fort Vacherauville, were entirely of reinforced concrete), and because the nature of the soil allowed the garrison to dig themselves into shelters, proof against even the 42-cm., right under the concrete masses of the forts.

In contrast to these conditions the fortress of Antwerp was built on a uniformly flat site, with water only three feet below the surface. This made it necessary to build all the fortifications above ground and to forego the advantage of deep shelter. The forts were of simple concrete, proof to 21-cm. shells at most. The whole Belgian army was in the line from the outset without hope of reinforcements, fresh artillery, or relief. Added to this, the army, which had at all costs to avoid being surrounded in the fortress, had a vulnerable flank.

It will be seen, therefore, that Antwerp, Port Arthur and Verdun represent three absolutely distinct military situations.

German Occupation: Reconstruction of the Fortress.—Once masters of Liége and Namur, the Germans had lost no time in repairing all the works. They restored the concreted works to their original thickness and filled up all fissures and craters. At Namur most of the cupolas were replaced, but at Liége on the contrary they removed all guns and even numerous armour parts, and proceeded to organize the forts exclusively for infantry and machine-guns. The mechanical and telephonic installations and the ventilation system were improved.[2] Door and window apertures were made smaller and a great number of the latter walled up.

At Antwerp, as at Liége, the Germans converted the forts into infantry works in accordance with the principles already applied at Metz. They restored the earthworks of the forts, but did not as a rule reconstruct the chambers destroyed by bombardment. Chambers not taken into use were walled up. In the intervals they maintained only the western and northern fronts. On the west front (Blaesveld-Bornhem and the left bank of the Scheldt) the existing trenches were consolidated and formed into two lines joining the gorges of the permanent works. A considerable number of small concrete shelters also were built here for machine-guns or observers, and some for flanking guns. On the north front, facing Holland, from the Lower Scheldt to Fort Schooten, the Germans took pains to maintain in good order the old permanent forts and the interval trenches. The latter were made into a continuous system, generally double, with communication trenches, and concrete shelters and posts. In front were two continuous belts of wire. The flanking was ensured by the traditore batteries of the repaired works and by concrete machine-gun emplacements. This line was prolonged by an analogous organization, facing north, all along the Turnhout canal up to and including that town.

The defence system of the river as organized by the Germans consisted of the following elements (all save the last-named on the right bank): *Santvliet gun-spur* (four emplacements for railway guns on pivot platforms, two for 28-cm. guns, two for two 17-cm. guns paired; near the platforms were reinforced concrete shelters for ammunition and personnel); *Blauwgaren battery* (four 12-cm. guns in separate reinforced concrete shelters); *Lillo battery* (four 15-cm. guns without overhead protection); *Liefkenshoek battery* (two 12-cm. guns in concrete shelters); *Ste. Marie battery* (six 24-cm. guns in casemates).

[1] On Feb. 21 1916 there were in the Verdun system 11 divisions. By July 1, 54½ other divisions had done duty in the line, making a total of 65½. Of this total on an average about 27 were present at any one time. (C. F. A.)

[2] Belgian and German accounts of the siege of Antwerp concur in noting the inadequate ventilation of the forts and the effects of this on their resisting power. (C. F. A.)

To sum up, the Germans in restoring the fortress of Antwerp treated the permanent works on the principles applied at Metz, and the intervals as if they formed part of an army front.

BIBLIOGRAPHY.—The Belgian official account of the operations of 1914 appears in instalments in the *Bulletin Belge des Sciences Militaires*. An official German account (*Antwerpen 1914*) by E. V. Tschischwitz, senior general staff officer III. Reserve Corps at the siege, was published in 1921 at Oldenburg. For the British part the official naval history by Sir Julian Corbett should be consulted.

(R. VAN O.)

AOSTA, DUKE OF (EMANUELE FILIBERTO) (1869–), Italian general, was born Jan. 13 1869, the eldest son of Prince Amedeo of Savoy, Duke of Aosta (*see* 1.804), and Maria Vittoria, Princess of Pozzo della Cisterna (1847–1876). In 1895 he married Princess Hélène of Orleans, daughter of the Comte de Paris. Devoting himself seriously to the military career, he in due course commanded the 1st Div. at Turin and the X. Army Corps at Naples. A very serious illness caused a break in his career, and on the eve of Italy's entry into the World War he was still on the reserve list. Following upon the clash between Cadorna and General Zuccari, who had been appointed to the command of the Third Army, the duke was chosen to succeed the latter, and he retained this post throughout the war. The duke's command of the Third Army was conspicuously successful. His task was thankless, for the duty of his army was to hammer against the iron ramparts of the Carso. Various notable successes were won, though the territorial gains were very limited, and in the process of wearing down the enemy the Third Army played a great part. The duke's rank possibly told against him to begin with; but the qualities which he showed speedily made it clear that he was no figurehead, and that he held his command by merit. In the end the fact of his being a royal prince was only a help to the position he had established for himself, for it put him outside the field of ordinary jealousies. He had the invaluable faculty of establishing harmony and a spirit of coöperation among his subordinates, and he won a great popularity among the troops, for whose welfare he did all that lay in his power. His qualities as a leader were so highly estimated that he would probably have been chosen to succeed Cadorna if it had not been thought unwise to place upon a royal prince the responsibility of so grave a moment.

The Duchess of Aosta served throughout the war as inspectress-general of Red Cross nurses. In spite of delicate health, she rose superior to continuous fatigue and frequent hardship, and the award to her of the silver medal for valour was no mere compliment. Their two sons Amedeo, Duke of Apulia (b. 1898), and Aimone, Duke of Spoleto (b. 1900), both served in the war.

APPONYI, ALBERT, COUNT (1846–), Hungarian statesman (*see* 2.226), was from 1906 to 1910 Minister of Education in the Wekerle Cabinet. In consequence of Francis Kossuth's illness Apponyi undertook the greater part of his business as president of the party of Hungarian Independence, calling itself the party of 1848. In the message sent to the party just before his death Kossuth designated him as his most suitable successor. At the outbreak of the World War he adopted in Parliament the standpoint of a "truce of God." Together with Count Julius Andrassy and Rakovszky, Apponyi was from July 6 to Aug. 25 1916 a member of the commission established by the Hungarian Chamber of Deputies to watch over the conduct of foreign policy. In internal affairs Apponyi fought for universal suffrage. After the outbreak of the October revolution of 1918 he retired for a time into private life. In 1919 he was elected as a non-party deputy to the National Assembly, and was head of the Hungarian peace delegation in Paris. He became a member of the League of Nations Union, and as a politician standing outside party was in 1921 perhaps the most influential man in Hungarian politics.

His published works include: *Recollections of a Statesman* (1912); *Die rechtliche Natur der Beziehungen zwischen Oesterreich und Ungarn* in the *Oesterreichische Rundschau* (vol. xxviii); and in Hungarian *Hungary in the World's Press* (1915).

ARABIA (*see* 2.254).—The political frontier of Arabia on the N. was indeterminate in 1921 except in so far as the boundaries between Syria, Palestine and Mesopotamia, as laid down in the

Franco-British Convention of Dec. 23 1920, affect it (*see* SYRIA). The limits of the various independent states of the peninsula, with the exception of the N. boundary of the Aden protectorate, all remain equally undefined. A natural frontier on the N. runs in an irregular curve from Akaba ('Aqaba) first N.E. and then S.E. to the Persian Gulf, following the fringe of cultivation, which fluctuates according as the nomadic or sedentary population is the stronger. This line excludes Kerak, but leaves the transition area of the Hamad or Syrian Desert within Arabia, to which, both physically and ethnographically, it seems to belong.

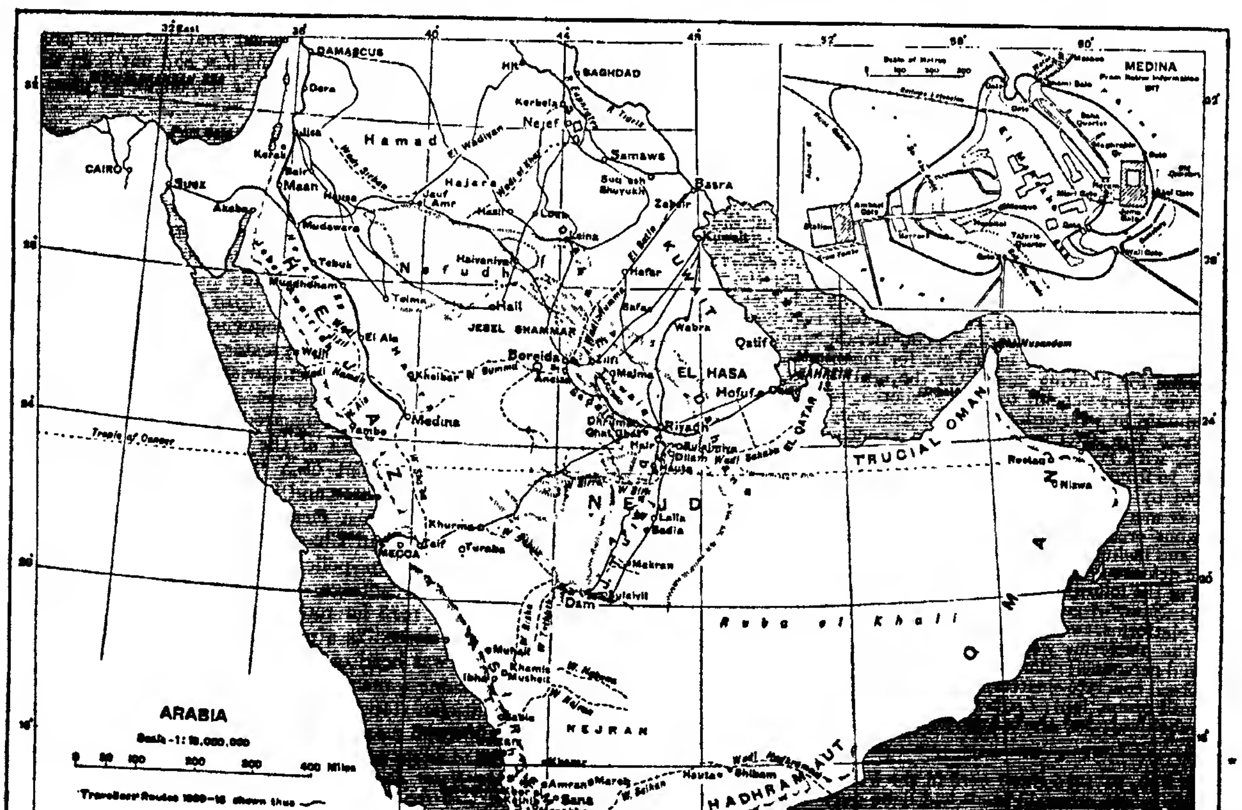
Topography.—Up to 1914, even the best knowledge of Arabia was sketchy, but considerable advance has since been made by the discoveries of recent travellers and as a result, direct or indirect, of war operations. The progress to be noted falls under three main heads: new light has been thrown on the drainage of the peninsula; the positions of a number of places, previously very imperfectly known or only guessed at, have been accurately fixed; and a vast amount of topographic and ethnographic detail has been accumulated.

The compilation of the map of Arabia on the million scale has kept pace with discovery. For this purpose, the route traverse in northern and central Arabia from Huber's *Journal*, extending over 3,000 m., was replotted on a large scale and formed a groundwork on which to place the more hurried surveys of Wallin, Palgrave, Doughty, etc. All the labours of recent travellers, starting with Leachman (1910), and ending with Bell (1914), were reconsidered from the originals and adjusted with due regard to the proportionate value of each, while the information collected by Col. Lawrence during the World War and the surveys of Philby were incorporated. The work of compilation was undertaken by D. Carruthers in 1914 and in 1921 was still in progress. Provisional sheets covering the northern half of the country had already been issued.

The course of the main watershed of Arabia can now be traced with general accuracy. Prolonged northward from the highlands of Yemen and Asir, it passes inland between Taif and Wadi Turaba and runs E.—not W. as was previously supposed—of the Hejaz railway through the Kheibar *harra*, or lava outcrop. Perhaps some of the higher peaks of the 'Aweiridh ridge overtop it.

Wadi Hamdh, the main drainage basin of the short western slope of Arabia, previously thought to have its head-waters in the vicinity of Medina, at about lat. 24° N., in all probability has its source in W. 'Aqiq, at least 3° farther S., thus giving it a total length of 700 to 800 m. including windings. The 'Aqiq, rising S.W. of Taif, passes well to the E. of Mecca and W. of Medina and is said to take the name W. Shaiba between these two towns. Some doubt remains whether the Shaiba discharges wholly into the Hamdh just N. of Medina, or whether it also forms a tributary eastward in W. Rumma (Rima). Wadi 'Ais, coming from the N., and W. Jizil from the S., and joining W. Hamdh in the plain of Jurf are its two main affluents, and their courses, together with the middle reaches of the Hamdh, have been explored in great part and mapped.

Much new information has been obtained as to the drainage of the long eastward slope—effected mainly by the great wadi systems of the Dawasir, Sahaba and Rumma (naming from S. to N.). The town of Dam, in W. Dawasir, central Arabia, previously mapped near lat. 23° N., has had its position definitely fixed in lat. 20° 27′ N. and long. 44° 40′ E. The direction of the course of W. Dawasir, a matter long in dispute, proves to be S.E. towards the Ruba'el Khali, or Great Southern Desert, and not N.E. as the old maps show. The point of junction of the important Asir wadis—Ranya, Bisha and Tathlith—is in all probability in the plain of Hajla about 50 m. N.W. of Dam. As to W. Sahaba, which has a practical monopoly of the surface-waters of the central mass of Arabia and the drainage of which trends to the sea at the southern end of El Qatar, it was found to have its remotest head-waters in W. Sirra in the very heart of the peninsula. Under the name of W. Birk, the Sirra breaks through the Tuwaiq plateau and, turning northward as W. 'Ajaimi, joins W. Hanifa some 60 m. S.E. of Riyadh (lat. 24° 37′ N., long. 46° 41′ E.). W. Hanifa ultimately falls into the Sahaba, but the latter probably carries no surface-water, at any time, farther than the western fringe of the Dahana, about long. 48° E. Wadi Subai, rising somewhere in lat. 22° N., is probably the most southern tributary of W. Rumma.



Jebel Tuwaiq, the salient physical feature of central Arabia, was found to extend for some 60 m. S. of Wadi Dawasir—much farther S. than was previously suspected—giving this crescent-shaped plateau a length from Zilfi (lat. 25° N.) of over 500 m. It has an average breadth of 20 m. and a mean elevation of nearly 3,000 ft. above sea-level and 600 ft. above the great plain on the west. The positions of the southern Nejd oases, most of which are situated on or around the Tuwaiq plateau, have been ascertained; and much further light has been thrown on the limits and peculiar character of the Nefudh and Dahana sand-belts on the N. and N.E. respectively, the former proving to be comparatively hard gravelly plain covered at intervals with parallel sand-belts of varying width and the latter a continuous area of deep sand forced by wind pressure into high sand billows or dunes.

Exploration.—The journeys of recent travellers have been mostly confined to the central and northern parts of Arabia; but a little new ground has also been broken in the W. and S.W. Some of these explorers, notably Philby, Shakespear and Bell, made route traverses by prismatic compass, checked at intervals by determinations of lat. and long. which greatly enhanced the value of their work (*see* Map).

Central Arabia.—Foremost among the explorers since 1910 is H. St. J. B. Philby. In 1917, when on a mission to the emir of Nejd, he crossed the peninsula from sea to sea, a feat previously accomplished by only one other European—Capt. Sadlier, in 1819—his line being from 'Oqair ('Ojair) on the Persian Gulf to Jidda, by way of Hofuf, Riyadh and Taif. He attributes the exceptional fertility of the Hofuf group of oases to the reappearance at the surface there of the rainfall of a very large area. Beyond Riyadh, Philby was the first European to follow, for most of the way, the great central pilgrim route to Mecca. He passed Ghat Ghat, a centre of the Wahabist revival (*see* AKHWAN MOVEMENT). After 80 m. of limestone desert alternating with belts of Dahana, his route lay across the highlands of Nejd, a granitic tract 150 m. in breadth, where he found altitudes up to 3,100 ft.; this tract forms part of the great divide between the N.E. and S.E. slopes of Arabia in which, in about lat. 23½° N. and long. 43½° E., lie the head-waters of W. Sahaba. For no less than 200 m. between the small settlement of Qusuriya, long. 44° 30′ E., and Khurma, lat. 22° N., long. 42° E.—a village of mud huts on the confines of the Hejaz and a point of conflict between the King of the Hejaz and the emir of Nejd—he found no settled habitation, but encountered vast herds of gazelles. After crossing the Rakba plain he reached Taif and, following down the gorge of W. Fatima, reached Jidda.

In a subsequent journey, May–June 1918, Philby explored southern Nejd, going 300 m. southward from Riyadh to Dam and back. His route outward lay through the previously unvisited oases of lowland Aflaj and W. Dawasir and he returned along the crest of Tuwaiq by way of highland Aflaj and El Fara. He determined astronomically the positions of a number of places, including Riyadh (lat. 24° 37′ N., long. 46° 41′ E.), Abu Jifan (lat. 24° 29′ N.), Hair (lat. 24° 21′ N.), Sulaiyil (lat. 20° 25′ N., long. 45° 29′ E.) and Dam (long. 44° 40′ E.), and ascertained various heights by aneroid readings. As a result of the journey, the hydrography of the Tuwaiq plateau, the backbone of central Arabia, is now as well known as any part before the World War. Philby's estimate of the population of Riyadh is 12–15,000, and its most conspicuous buildings are the palace of the emir and the great Wahabi mosque. The oases of Nejd were found to comprise, usually, a nucleus town with scattered hamlets, and not more than a few square miles of cultivated land around in each case; and populations never exceeding 10,000. In Aflaj and Kharj he made a notable discovery of ruin fields of considerable area, scattered with stone circles varying from 10–45 paces in diameter about heaps of rubble, in the middle of which usually stand large blocks of stone resembling the bases of pillars. Situated on hillsides some distance from cultivation, they suggest burial mounds of an early era, and open up an interesting field for investigation. In both districts, the peculiar system of irrigation from natural reservoirs or deep well pits by means of subterranean channels, or *karez*, was unexpectedly found to prevail. At Umm el Jebel, just S. of Laila, is a lake ¾ m. by ¼ m., possibly the largest sheet of permanent water in Arabia, and also a number of reservoirs of unusual size, one measuring 500 by 600 yards. In the Makran depression, S. of Badia (lat. 22° N.), are other perennial pools of water surrounded by woods of well-grown trees. The oasis of Dam (his main objective) locally known as "the wadi," Philby found to consist of some 20 separate settlements with a total population of 9,000, mostly of negro origin or of the Dawasir tribe. Dam itself has a population of about 3,000 and owes its importance to its situation near the line of trade between Yemen, Aden, Nejran (seven days distant), and central Arabia.

The negative results of Philby's journeys were almost as valuable as the positive: he found that the Nejd oases are not tropical paradises; that there is no chain of oases linking Nejd with either Asir or Yemen; and that there is no region of fertility between southern Nejd and Oman, or any settled spot between it and either Oman or Hadhramaut.

Northern Arabia.—In 1910, Lt.-Col. G. E. Leachman set out from Kerbela for Hail (J. Shammar) and Riyadh, but, after passing Leina, he had to return to Samawa. Again, in 1912, he left Damascus intending to cross Arabia from N. to S. He got as far as Riyadh by way of Hazil, Leina, and Boreida, but the emir of Nejd refusing him safe conduct, he was obliged to turn eastward and emerged by the usual road through El Hasa to 'Oqair. As a result of these journeys he drew attention to W. Khar, an important affluent of the Euphrates, and discovered its possibilities as a line of communication between Syria and Iraq via the oasis of Jauf, noting that water is obtainable at regular intervals along it. He was first among Europeans to visit the remarkable wells of Leina, of which there are several hundreds, spread over an area of 5–6 sq. m.; and he is the only European who has made any record of a journey from J. Shammar to Suq esh Shuyukh. His travels were equally important politically, for he laid the foundations of a good understanding between Britain and the emir of Nejd; he was treacherously shot, Aug. 1920, in Mesopotamia.

In 1913–4, Miss Gertrude Lowthian Bell travelled alone, except for native guides, from Damascus to the neighbourhood of Teima. Thence she passed eastwards over new ground along the southern margin of the Nefudh to J. Shammar and visited Hail; then northwards by Loqa to Nejef and Bagdad. The latter part of the route was especially valuable, as it added considerably to knowledge of a region hitherto traversed only by Wallin in 1848. Miss Bell is the only woman traveller in Arabia, with the exception of Lady Anne Blunt, and one of the few women who can lay just claim to the title "explorer," for she surveyed her route by prismatic compass from start to finish.

Capt. Shakespear, British political agent at Kuwait, who became political officer in Nejd in 1914, travelled much in northern and central Arabia. He made compass traverses of his journeys and left voluminous notes which proved of great value. In 1913–4 he crossed the peninsula from Kuwait to Suez by way of Riyadh, Boreida, Haiyaniya and Jauf el 'Amr, following an entirely new course beyond the last-named place. He was killed in action Jan. 24 1915 in a conflict between the forces of Ibn Sa'ud and Ibn Rashid whilst on special duty with the former; his death was a grievous loss to the Indian Political Service, to which he belonged, and to geography.

In 1909, Douglas Carruthers went, primarily, in search of the little known *oryx beatrix*, a rare antelope inhabiting the interior of Arabia, which hitherto had not been hunted by any European, and he obtained a complete series of skins and horns. His route, from Jiza (Ziza) in the Belqa, lay through an unmapped region, Guarmani, in 1864, being his only forerunner, except at Teima. He surveyed his route southwards to Teima, thence northwards along the Nefudh towards Jauf el 'Amr, and back to Jiza.

Alois Musil, in 1908–9 and again in 1910, explored extensive tracts between lat. 27° and 36° N. and long. 37° and 44° E., embracing the Hamad, W. Sirhan, Hajara and Wadiyan. He is reported to have made plane-table surveys of parts of these regions which should furnish valuable data towards the mapping of northern Arabia; he added greatly to knowledge of its ethnography, natural history and archaeology. He is the only European who may be said to have penetrated the Hamad to any great extent.

In 1912, a journey from Kuwait through Zilfi, Boreida, and Riyadh to Hofuf and the coast again was made by Barclay Raunkiaer on behalf of the Danish Geographical Society; he made a prismatic compass survey of his route which to a small extent covered new ground. Raunkiaer died in Copenhagen, July 1915.

Capt. Aylmer and Capt. S. S. Butler, in 1907, opened up comparatively new ground between Bagdad and Jauf.

The Hejaz.—The Arabian section of the Hejaz railway was so ill-known before the World War that even the stations could not be enumerated correctly. Determination, in 1917, of the lat. and long. of Ma'an and the observation of the long. of a few stations to the S. enabled valuable adjustments to be made in the trace of the line. A belt of the Hejaz slope, some 300 m. in length between Wejh and Rabugh and a smaller tract immediately S. of Akaba were pretty thoroughly explored as a result of war operations, and a Turkish staff map of the country within a 30-m. radius of Medina which fell into British hands added further useful data, so that a great part of the Hejaz can now be mapped with fair accuracy. Much was learnt about the Billi tribe who people the rolling country between Wejh and the railway. They were found to be pure nomads without a single settlement in their district except one small garden at El Kurr; while the Juheina and Harb to the S. of them are less nomadic.

Asir and Yemen.—Towards the end of 1918, in the course of Idrisi's final campaign against the Turks, British officers could mix somewhat freely with his people on the coast and were able to meet tribesmen from the least known parts of the interior, and so an amount of knowledge, topographical, social and political, was gained. In particular, the composition and distribution of the chief tribes of Asir and Yemen was learnt. The position of Ibha (formerly Menadhir), the headquarters of the Turks, was at long last ascertained, though no European got there even when they surrendered. Sabia, Idrisi's capital, about 23 m. N.N.E. of Jeizan, was visited by an Indian medical officer who, for the first time, was able to describe

this hut village. In Yemen, in 1909, a considerable amount of survey work was done by M. A. Beneyton, a French engineer, for a proposed railway from Hodeida to San'a and 'Amran (see below) and, as a result, much unexplored territory was mapped on a scale of 1:250,000. G. Wyman Bury went from Hodeida to San'a in 1912, and made a long stay at Menakha in the same year. He has thrown more light than perhaps any recent traveller on the topography and economic conditions of Yemen. A. J. Wavell visited San'a in 1911 and gave the best description of the city since Manzoni, 1884. He found the population reduced to 18,000 as compared with Harris's computation of 50,000 in 1891. The decline in population and the commercial depression prevalent in Yemen may be attributed largely to the lawlessness of the intractable Zaranik and Qahtan tribes who occupy the country between the highlands and Hodeida.

Aden Protectorate and Hadhramaut.—There is little new information regarding these districts. Bury, in 1911, described his penetration of the Kaur watershed (alt. 7–9,000 ft.), N. of the Yafa' Fadhli country. He visited Yeshbum (pop. 4,000), the capital of the Upper 'Aulaqi, situated in a plain producing cotton and indigo and carrying on an industry in cotton fabrics, and got as far as Beihan, 110 m. inland of Shughra and almost in touch with Mareb.

The Red Sea Coast.—The naval patrol during the World War added much to knowledge of the very intricate coastline from Akaba to Aden. The triple coral reef fringing it had kept this coast almost inviolate, but the very numerous openings through the reefs are now known and have been charted.

Political History.—Before the World War, the Porte claimed control of Arabia in its entirety as rightfully part of the Ottoman Empire in virtue of the Sultan's authority as caliph. In actual fact, most of the peninsula was under a number of independent native rulers, only some of whom acknowledged Ottoman influence, and that to a limited degree, while others were under British protection. Effectual Turkish jurisdiction was confined, in the Hejaz, to the two Holy Cities, their ports, and the line of railway; in Asir, to one or two small ports and the inland districts of Ibha and Muhail; and, in Yemen, to certain garrisoned towns in the interior and to the ports of Hodeida and Mocha and connecting roads. The Hejaz railway, built nominally for the benefit of pilgrims to Mecca but in reality to increase the Ottoman hold on Arabia, did not fulfil political hopes, partly because it served not more than a third of the territory that the Turks claimed and partly because of the immense difficulties of its maintenance and working; and it brought about little or no economic development in the peninsula.

The World War marked the passing of Turkish control from the whole of Arabia and, at the opening of 1921, there existed the following principal autonomous elements: the kingdom of Hejaz; the emirate of Nejd and El Hasa; the emirate of Jebel Shammar; the principality of Sabia in Asir; the imamate of Yemen; the sheikhdoms of Kuwait, of Bahrien Is., and of El Qatar; the Trucial Oman; the sultanate of Muscat in Oman; the Ka'aiti and Kathiri sultanates of Hadhramaut; and the autonomous tribes under treaty with Aden. But this list does not exhaust the autonomies, for there are many tribal communities—settled, half-settled and nomadic—which owe allegiance to none but their own local chiefs, such as certain sections of the Anaza and Muntefiq in the N. and the Zaranik and Yam in the S. The parcelling of the peninsula among so many separate communities is largely the result of peculiar geographical conditions which hardly admit of homogeneous settled life except in certain favoured districts, or in oases or wadis; and it is only by virtue of some peculiar source of wealth, some common spiritual ideal or some external support that larger territorial dominions have been established.

The Hejaz.—War with Turkey entailed on Great Britain and her Allies certain dangers in Arabia owing to the efforts made by the Central Powers, through the Porte, to arouse Moslems to a *jihad* or Holy War. Whether this result followed or not, there was every likelihood that the Turks would try to hinder the free use of the sea route to the East and, if left in control in western Arabia, that Aden and the possessions of the Allies in East Africa and the Farther East would be dangerously accessible to the enemy. Great Britain therefore turned to the sherif of Mecca (Husein Ibn 'Ali), believing that the metropolitan position of the Holy Cities of Islam and the venerated lineage of the sherif would make very effective his refusal to countenance a *jihad*, while if he declared against the Turks, the geographical position of the Hejaz would make the materialization of the other dangers improbable. Sherif Husein was known to desire the emancipation of the Meccan emirate.

Under the Ottoman régime, the Hejaz was a *vilayet*, with a *vali* resident at Mecca. Nominally, it included all the area S. of Ma'an to Lith, and was subject to taxation; but the cities of Mecca and Medina were not only tax free but were in receipt of subsidies from the Ottoman treasury, as were also certain Harb sheikhs who were able to interfere with the passage of pilgrims or with the railway track. The whole vilayet was exempt from service in the Turkish army and successfully resisted an attempt to impose conscription in 1914. The Porte maintained forces in the Hejaz, the normal garrison being about 7,000.

Side by side with this foreign government, existed the authority of the sherif or emir of Mecca, enjoying extra-territorial independence at Mecca and Taif with the right to keep official representatives to watch over his interests at Medina, Jidda and elsewhere. The emir was able, at need, to call out considerable levies of Hejazi and other Bedouins and, by so doing, under semblance of helping the Turks, successive emirs not only made interest with the Porte but inspired it with a wholesome respect and, at the same time, kept in touch with a fighting force which could be used some day for their own ends.

Sherif Husein was nominated to the emirate in 1908, as a man of pacific character, likely to serve the Porte's purpose. In 1910 he took up arms for the Turks against the Asiri revolt under Idrisi. In the same year he extended his influence over a part of the territory of the emir of Nejd in central Arabia. But in 1913 he began to pursue an active anti-Ottoman policy, ostensibly opposing the extension to Mecca of the Hejaz railway and supporting the Harb tribesmen in their resistance to this and other Turkish projects; and he organized the Hejaz tribes acknowledging his authority, with a view to insurrection. He reconciled himself with Idrisi and tried (without success) to get the support of the imam of Yemen in his anti-Ottoman aim; and, in 1915, he sent 'Abdalla, his second son, to bring about a truce between the emirs of Nejd and J. Shammar.

In the summer of 1915, Sherif Husein declared his desire for a revolt to the Allies, who thereupon agreed to support him with money, munitions and supplies. A long period of inaction followed, however, and it was not until June 1916 that the revolt actually broke out. After the loss of Jidda, Mecca and Taif by the Turks, Husein proclaimed himself independent of Ottoman rule June 5 1916. To explain his attitude to the Moslem world, he issued a proclamation (Aug. 1916) setting out a number of indictments against the Committee of Union and Progress; and, finding that the Ottoman Government was unable to spare any large force to oppose his aims, he was formally proclaimed "Sultan of the Arabs" in Oct., a large number of chiefs assembling in Mecca to support him. He relinquished this title for that of "King of the Hejaz" in Dec., and was so recognized by the Governments of Great Britain, France and Italy. In 1917, Wejh and Akaba being lost by the Turks, the newly established kingdom was able to maintain its separate existence, and the year 1918 witnessed further satisfactory developments. In spite of the Armistice, the Turks refused to surrender Medina until Jan. 1919. The Hejaz was represented at the Peace Conference by the Emir Faisal, King Husein's third son, and the state was admitted a member of the League of Nations in 1920. By the treaty of peace with Turkey, that country renounced all rights and titles to the Arabian peninsula and the King of the Hejaz undertook to ensure free and easy access of all Moslems to the holy places of Mecca and Medina. The treaty had not, however, been ratified by the Hejaz at the beginning of 1921.

King Husein maintained friendly, but formal, relations with the emir of Nejd during the World War; but, in 1919 and the early part of 1920, there was frequent friction between them over the debatable border at Khurma in the neighbourhood of Taif. A battle at Turaba, near Taif, in May 1919, resulted in a loss of 4,500 men to the Hejaz army; but the emir of Nejd did not follow up his advantage. In June 1920, relations between the dis-

putants were reported to be more friendly; but the frontier still remained undefined in 1921.

The Central Emirates.—The emirate of Nejd, capital Riyadh, and that of Jebel Shammar to the N., capital Hail, comprise all the country between the main northern and southern deserts of Arabia. Between the two emirates lie the oases of Qasim and Sedeir, the overlordship of which has been in dispute for more than two generations. The two emirs control, more or less effectively, all the peoples both settled and nomadic of central Arabia, and the authority of the emir of Nejd extends to El Hasa on the E. and to certain tribes of the Asir border and Wadi Dawasir on the W. and S. Wahabism, or its more modern manifestation the Akhwan movement, supplies the moral basis of the power of the emirate of Nejd, while the settled nature of the population is its material basis. The emirate of J. Shammar, on the other hand, grew out of the desert power of a great nomadic society accustomed to maintain a group of permanent villages and hamlets around J. Aja and Selma, which served as rallying places and as market centres. The Shammar emirate, while inferior to its rival in wealth and settled population and lacking its religious tie, owes its strength to the unity existing between its oasis folk and the tribes of the surrounding regions, to the patriarchal tie binding them, and to the stimulus of the steppe desert upon its life.

Nejd (*see* 19.351) comprises all the oasis groups situated about or on the Tuwaiq plateau, extending well over 500 m. from N. to S., and is directly or indirectly under the rule of Ibn Sa'ud of Riyadh. In addition, the emir lays claim to El Hasa, on the Persian Gulf between lat. 24° and 29° N. He drove the Turks from this district—which they had occupied as a sanjaq of Basra since 1871—in May 1913, and was acknowledged by the Porte as *vali* of Nejd and El Hasa. He, however, effectively occupies only the Hofuf group of oases, with the ports of Qatif and 'Oqair. In 1914, Ibn Sa'ud entered into relations with the British Government—Capt. Shakespear being appointed political officer in Riyadh—and proved an unswerving ally throughout the World War. He declared himself definitely against Ibn Rashid, emir of J. Shammar, who had allied himself with the Turks. He fought a drawn battle with Ibn Rashid at Mejma' in 1915, the main point in dispute being the ownership of Qasim with the towns of 'Aneiza and Boreida; it was in this battle that Captain Shakespear was killed. His attitude towards the Hejaz, while war lasted, was friendly but formal. By 1918, after intermittent and generally successful campaigns against the emir of J. Shammar, Ibn Sa'ud had established his supremacy in central Arabia, including Qasim and Sedeir. His relations with the King of the Hejaz, in 1919–20, became less cordial, frequent disputes having arisen over the frontier question. He is believed to have steadfastly refused either spiritual or temporal allegiance to King Husein. Early in the summer of 1920, Ibn Sa'ud turned his attention to E. Arabia and instigated an attack on Kuwait, which port he is said to covet. Several actions took place but without definite result, and subsequently efforts were made on the part of the British Government to bring about a territorial agreement between the emir and the sheikh of Kuwait.

Before the World War, the authority of Ibn Rashid was supreme in the group of oases about J. Aja and J. Selma; in the steppes N. of Qasim, from the Hejaz border (including the oasis of Teima) almost to Kuwait; and in the oasis of Jauf el A'mr. On the N. and E., the southern Nefudh and the Dahana formed a neutral zone between his territory and the nomad tribes beyond. Ibn Rashid's attitude in the World War was consistently pro-Turkish, though relations between him and the adherents of the Committee of Union and Progress were probably never cordial. The comparative ease with which the Turks could reach Hail, from either the Hejaz railway (at Mu'adhdham) or from Samawa and Nejef, contributed towards making him sensitive to Ottoman pressure. He was reported to have supplied the Turks with large numbers of camels, especially for the expedition against Egypt in 1915–6. As the World War proceeded, his power diminished, both territorially and economically. While Ibn Sa'ud was fighting the Turks in El Hasa (1913), Ibn Rashid was able to maintain his position; but, in 1915, an attempt on his part to overrun Qasim and Sedeir resulted in the loss of the towns of 'Aneiza and Boreida, and they were placed under tribute to Ibn Sa'ud. The oasis of Jauf, on the caravan road from Damascus to Hail, was seized in 1910 by the Ruweila tribe of the Anaza under Nuri esh Sha'lan, one of the most powerful and anti-Turkish of the nomad chiefs. Nuri had shown himself a successful rival of Ibn Rashid, for, in spite of determined attempts on the part of the latter to regain the oasis (notably in 1914), he was not able to reëstablish his authority in Jauf. The important oasis of Teima, also, reverted to the Hejaz in 1917. In the same year Ibn Rashid went to reside at Medain Salih and, for a year, did not set foot in his capital. In May 1920, his murder was reported.

Asir.—The limits of this district are indeterminate, but broadly it comprises the country lying between the territory under the jurisdiction of the King of the Hejaz—who claims control of the Tihama down to Qunfuda—and that of the imam of Yemen. Its eastern limit is contiguous with Nejd. There is a strong political and social distinction between the people of the Tihama lowlands and those of the highlands which constitute Asir proper; and there is no part of Arabia where the tribal elements are so sharply defined and their boundaries less changeable. Settled tribes are the predominant element in Asir, as the physical conditions favour the pursuit of agriculture sufficiently to render nomadism unnecessary. In religion, practically all the tribes are Shafei Sunnites; Wahabism has a few adherents and its tenets are regarded sympathetically all over the district; but everywhere there is a strong antipathy to Zeidism.

Asir cannot be regarded as a political entity. In 1914, it fell into four parts—sections acknowledging the Turks, the Idrisi of Abu 'Arish, and the sherif of Mecca respectively, and small groups of nomad tribes on the E. who recognized no authority. The Turks claimed the whole of Asir as the northern section of the *vilayet* of Yemen, but never succeeded in subduing the country and, in reality, they only precariously held the inland towns and immediate surroundings of Ibha and Muhail and the port of Qunfuda, all of which they garrisoned. The authority of the Idrisi was restricted to a strip of the Tihama some 80 m. long and extending about 40 m. inland to the scarp of highland Asir, with Sabia as capital and Jeizan and Midi as ports. The influence of the sherif of Mecca was mostly confined to the Ghamid and Beni Shihir tribes on the inland side of the ridge.

Interest in Asir, during the World War, was centred on the Idrisi, Seyyid Mohammed. His aim throughout was to rid the district of Turkish control and to extend his own influence. By 1910, he had much reduced the Ottoman hold and, in 1911–2, subsidized and supplied by the Italians during their war with Turkey, he consolidated his position. In 1914, failing to obtain sufficient recognition of his power from the Turks, he declared himself definitely against them. He concluded an agreement with the British resident at Aden in May 1915, and was supplied by the Allies with material. He raised part of the Zaranik tribe and took the field, ostensibly against the Turks, with a nominal following of some 12,000 men and overran the Tihama of Yemen, but failed to capture Loheia, one of his main objectives.

In reality, his support of the Allies was not of a very positive character, as he was in constant fear of attack by the imam of Yemen; and the Turks held Ibha and Muhail, their strongholds in the interior, until the Armistice. He kept on good terms all the time with the King of the Hejaz. The actual extent of the Idrisi's control of Asir, at the beginning of 1921, still remained a matter of doubt; but his attitude towards the imam of Yemen continued to be hostile, though there had been short periods of truce between them. In Feb., information reached England that Idrisi forces had occupied Hodeida.

Yemen.—As in Asir, the social contrast between the highlands and lowlands is very marked, being the outcome of religious and racial differences reinforced by strongly contrasted geographical conditions. Broadly speaking, the central highland population is Zeidite (Shiah) and accepts the authority of the imam, whereas

the population of the Tihama and the extreme N. and S. is predominantly Shafei and is strongly opposed to him. In consequence there has hardly ever been any semblance of administrative unity in the province. It is difficult to state the imam's territorial title as distinct from what he claims. While the Turks were in Yemen, there were districts or tribal groups (*e.g.* in the Yemen interior) who repudiated them, but were not unwilling to accept an imam wholly independent of them; there were others who accepted the Turks, but would have nothing to do with the imam except under pressure (*e.g.* the Isma'iliya, the Daudiya sect along the Hodeida-San'a road, and most of the northern Tihama tribes); and there were others again, such as the Zaranik, between the coast and hills S. of the Hodeida-San'a road, and the Beni Yam in the interior, who accepted neither Turk nor imam.

The imam Yahya Ibn Mohammed came into power in 1904. After his revolt against the Turks (*see* 2.270), a patched-up peace was made between them, but in 1911 his forces again beleaguered San'a. The city was eventually relieved by 'Izzet Pasha, who became military governor and succeeded, after some difficulty, in establishing an *entente* with the imam, "for the sake of peace among Moslems." An imperial firman, read at San'a on Sept. 22 1913, proclaimed a "mediatized status" or condominium, by the terms of which the imam secured the religious and social control of all the Zeidites (roughly all the highlands from the Asir border to the Aden frontier) together with part of the central Yemen Tihama, but he received no sanction to impose taxation.

On the outbreak of the World War, the imam refused to enter into relations with Aden, and was strongly opposed to the Idrisi. In 1915, he showed his leaning towards the Turks, by writing a letter to Enver, "praying for the success of the Ottoman armies." He refused to be drawn into any alliance with the sherif of Mecca. Details of the actual happenings in Yemen during hostilities are somewhat obscure, but the imam's chief activity lay in attempts to tamper with the loyalty of the tribes of the Aden protectorate and Hadhramaut, in which he met with partial success. Later, he sought a closer understanding with the King of the Hejaz and, at one time, an alliance seemed possible, but did not materialize. The Turkish garrisons were withdrawn from Yemen at the end of 1918 and a small British-Indian force occupied Hodeida; but there was evidence that Turkish influence did not wholly disappear at the same time. In Aug. 1919, a British mission, sent from Hodeida in the hope of negotiating with the imam at San'a, was captured by Quhra tribesmen at Bajil about 25 m. inland, and was detained until Dec., when it returned to the coast without having accomplished its purpose. In March 1920, the garrison of Hodeida was temporarily increased owing to the uncertainty of the attitude of the imam and some of the Tihama tribes. In Jan. 1921, the forces of the imam, commanded by Mahmud Nedim Bey, the former vali of Yemen, were reported to be attacking the Tihama regions—the conquest of which appeared to be his main objective—and were threatening Hodeida. In Feb., the occupation of Hodeida by Idrisi troops was reported.

Persian Gulf States.—The sultanates and sheikhdoms, which extend along the Arabian shores of the Persian Gulf, have all come under British influence, in one form or another. Their rulers are controlled in matters of external relations, and maintain their authority internally by grace of their alliance with Great Britain. None rule effectively over territory more than about a day's march from the coast. The states are as follow:—

Oman.—The Sultan of Muscat (*see* 20.99 and 19.43), claims overlordship of all territory extending from Hadhramaut to the entrance of the Persian Gulf (including Dhofar) and, inland, to the Great Desert. In reality his direct rule is restricted to the town of Muscat and a stretch of coast N.W. and S.E. of it. The tribes of the interior are practically independent and have set up an Ibadhi imamate, and if not fighting among themselves are a constant menace to the sultanate. The sheikhs of Rostaq are among the most powerful of these independents. In 1912, under the insistence of the British Government, a warehouse was established at Muscat to control the traffic in arms and ammunition through Oman ports to the interior, which had been greatly abused. A rising of the Ibadhis against the Sultan, for which this control was made part pretext, took a serious form in 1913-4 and necessitated the bombardment of the ports of Quryat and Barka, and an Indian force occupied Beit el Felej near Muscat. The rebels attacked in strength in Jan. 1915, but met with defeat, which relieved the situation. The disaffected tribes continue to dominate the interior, and the authority of the imam, rather than of the Sultan, is recognized by most.

Trucial Oman, formerly known as the Pirate Coast, extends for over 300 m. from El Qatar almost to Ras Musandam, and receives its name from the truce established in 1853 between the five recognized ruling sheikhs of the districts of Abu Dhabi, Dibai, Sharja, 'Ajman and Umm el Qaiwan. The position of the respective sheikhs is regulated by an agreement which, in 1892, placed all external relations under British control and made Great Britain responsible for their protection from aggression. The sheikhdoms are very unequal in importance—those of Sharja and Abu Dhabi are the most considerable territorially. The sheikh of Sharja claims to be paramount over all Trucial Oman, but this is repudiated by the other sheikhs and not recognized by Great Britain. An Arab political agent resides at Sharja.

El Qatar.—The sheikhdom of El Qatar comprises the peninsula of that name on the Arabian coast E. of Bahrein, of which latter it was formerly regarded as a dependency. Turkish control in El Qatar ceased in 1913, when the emir of Nejd drove the Turks from El Hasa, and the sheikh 'Abdalla ibn Jasim came into power in the same year. He maintained friendly relations with Britain and kept on good terms with the emir of Nejd.

Bahrein (*see* 3.212) consists of an archipelago, of which Bahrein is the most important island. The rule of the sheikh is effective only over that part of Bahrein I. adjacent to the port of Manama and over Muharraq I.: his authority over the remaining islands is little more than nominal. He agreed by treaty, in return for a subsidy, not to alienate any part of his territory except to Britain and to conform to British policy. A political agent, under the resident at Bushire, is stationed at Manama. Throughout the crisis in the pearl industry in 1913, and during the World War, the sheikh showed much goodwill to Britain.

Kuwait.—The Sultan of Kuwait (*see* 15.956), Salim, son of Mubarak, who succeeded his brother Jabir in 1917, claimed jurisdiction over 200 m. of territory from El Hasa almost to the head of the Persian Gulf, and ruled nominally westward to the wells of Hafar, where his district met that of the emir of J. Shammar on the N.E., and that of Nejd on the S.W. The late Sultan Mubarak formally repudiated all relations with the Turks at the outbreak of hostilities and his attitude towards the emir of Nejd was friendly, but towards the emir of Shammar intermittently hostile. In 1920, a serious attack on the independence of Kuwait arising out of the activities of the Akhwan sect of Nejd was threatened. Sultan Salim died early in 1921 and was succeeded by Ahmad ibn Jabir.

On March 1 1921, it was stated in Parliament that matters of policy and administration affecting Arab areas within the British sphere of influence and Aden were transferred to the Colonial Office; but questions regarding the Hejaz remained under the jurisdiction of the Secretary of State for Foreign Affairs. The tendency was for the British Government to rely considerably on officers of the Sudan Civil Service.

Trade.—Arabia produces little for export except pearls, dates, coffee, hides and skins; imports consist almost wholly of manufactured fabrics (cotton in particular) and food-stuffs (rice, cereals, flour, sugar and tea). Besides Aden only Muscat, Manama and Kuwait carry on any considerable direct and regular trade with the outer world—the first named with Europe mainly, and the others almost exclusively with India and the East; and Arabian trade in general commodities tends to focus more and more on Aden and Manama. The trade of Jidda—depending largely on the pilgrimages, and seasonal in consequence—though considerable, is of a more local nature and is mainly with Egypt, the near African coast and the Persian Gulf, and India at farthest. The trade of Hodeida, Jeizan, Mocha, Makalla, and the other still smaller ports is almost entirely carried on by sailing craft, though before the World War, Hodeida was also a port of call, at regular intervals, for certain smaller lines of steamers. Commercial enterprise at Arabian ports is mainly in the hands of Indians, especially in Oman, Kuwait, Hadhramaut and even at Aden; second to them come Italians, commercially predominant in many of the Red Sea ports (notably Hodeida), Italian Somaliland and Eritrea offering a convenient base of operations. Prior to the World War, British and Turkish interests were political rather than commercial: neither power had any strong hold on the economic activities of the country, the trade relations between Turkey and the Holy Cities excepted.

The following comparative table gives approximate trade figures (including specie), in thousands of pounds sterling, of the chief ports, in the years just anterior to the World War:—

	Year	Imports	Exports	Total
(a) *Western Littoral*				
Aden	1913–4	4,377	4,149	8,526
Hodeida	1912–3	789	490	1,279
Jidda	1912–3			1,482
(b) *Eastern Littoral*				
Muscat	1913–4	408	272	680
Manama (Bahrein) . .	"	1,878	1,740	3,618
Kuwait	"	371	114	485

The Western Littoral.—Trade was much disorganized during the World War and shifted from port to port as the exigence of the time demanded. Normal conditions were by no means resumed even in 1921. General trade figures were not available, but the following table gives (in round numbers) the trade movement between Aden and the chief ports, from 1914–9:—

(April 1 to March 31)	Jidda	Jeizan	Hodeida	Mocha
1913–4	£ 100,000	£ 5,000	£ 619,000	£ 251,000
1914–5	64,000	2,000	387,000	142,000
1915–6	2,000	33,000	1,000	757,000
1916–7	119,000	782,000	nil	34,000
1917–8	126,000	633,000	nil	nil
1918–9	50,000	538,000	5,000	nil

The marked increase at Jeizan was due to war operations in Asir; the almost total extinction of trade at Hodeida in 1916–9 and the temporary revival of Mocha, at the expense of Hodeida, to the blockade of the Yemen coast; and the sudden fall at Jidda in 1915–6 to the temporary blockade of the Hejaz coast just previous to the Arab revolt. There is normally a considerable direct trade between certain Red Sea ports and Egypt (Suez). In 1918, it amounted to about £E250,000 of which imports were £E225,000, chiefly cotton piece-goods (£E157,000), soap, dried beans, sugar and lentils; and exports, chiefly charcoal.

The main item in the trade figures of Jidda is the export of specie amounting, in normal times, to well over £1,000,000 annually. As to trade in general commodities, there is always an enormous excess of imports over exports, due largely to the requirements of pilgrims, the Hejaz producing little. In 1911, imports included rice £233,000 (from India); maize, wheat and barley £181,000; cotton piece-goods £150,000; silk goods and sugar, and, in that year, 287 steam vessels of 616,000 aggregate tonnage entered the port. Exports in the same year did not exceed £50,000 and consisted of skins and hides, wool, henna, gum and mother-of-pearl shells. The number of pilgrims passing through Jidda in 1912 was 83,295.

Midi (Asir), 45 m. S. of Jeizan, became a port of some importance during hostilities. In 1917, the construction of a stone pier for the discharge of cargo was undertaken.

Hodeida was formerly the most important of the southern Red Sea ports, but during the past decade its trade has steadily declined. In 1909, imports amounted to £650,000 and exports to £401,000, the latter consisting mainly of coffee, hides and skins. The Yemen coffee trade, valued at about £200,000 in 1911–2, has passed almost entirely to Aden on account of the greater security of the Aden routes and the better facilities there for husking the berries, and export. In 1921 the port was reported to be almost deserted. The scheme for a new harbour at Khor el Kethib, a good natural inlet 10 m. N., did not materialize.

The Eastern Littoral.—The following comparative table summarizes the value of the trade (including specie) of the chief ports, from 1912–20, the figures being in thousands of pounds sterling:—

Year	Muscat			Manama			Kuwait		
	Imp.	Exp.	Total	Imp.	Exp.	Total	Imp.	Exp.	Total
1912–3	464	301	765	2,240	2,295	4,535	438	132	570
1913–4	408	272	680	1,878	1,740	3,618	371	114	485
1914–5	328	275	603	758	462	1,220	292	43	335
1915–6	243	188	431	1,173	369	1,542	292	113	405
1916–7	..	..	..	1,530	780	2,310	472	152	624
1917–8	167	157	324	1,607	817	2,424	1,270	263	1,533
1918–9	290	242	532	1,350	1,318	2,668	994	259	1,253
1919–20	..	..	..	1,414	946	2,360	1,961	276	1,337

Muscat is the main trade outlet of Oman. The decline in trade after 1913–4, shown in the table, was due partly to the opening of Dibai in the Trucial Oman as a free port and partly to the control placed upon the arms traffic in 1912. The import of arms fell from £180,000 to almost nil in the period 1913–5. In 1918–9, 80 % of the total trade was with India, 12 % with the Arabian coast, and 4.5 % with Persian ports, and 42 steam vessels of gross tonnage 57,837 cleared the port; the tonnage carried by sailing vessels was 20,149. The most important article of export is dates (£123,000 in 1918–9), of which the better sorts of dry dates go to the New York and Boston markets; of secondary importance are pearls, mother-of-pearl and salt fish, mainly to India. Rice from India is the chief import.

Manama holds a somewhat similar position to Aden as a place of transhipment and centre of distribution for eastern and central Arabia. It is the headquarters of the Persian Gulf pearl industry, in which it is said that 5,000 boats are engaged. The exceptional decrease of exports 1914–6 (see above table) was due to the decline in the pearl trade, which fell in value from about £1,800,000 in 1912–3 to £320,000 in 1915–6, causing great economic stress. In 1919–20 the chief imports were rice £406,000, piece-goods £337,000, coffee £93,000, ghi £67,000 and sugar £33,000; exports, pearls £294,000 (£318,000 in 1918 and £702,000 in 1919), rice £261,000, cotton goods £219,000, and coffee. In the same year, 75 % of the trade was directly with India and 23 % with other ports of the Persian Gulf; and 56 steam vessels of 111,244 aggregate tonnage entered, of which 109,073 was British.

At Kuwait the principal imports (in 1919–20) were cotton piece-goods £384,000, rice £117,000, coffee £21,000, sugar and tea; and exports, rice £58,000 and ghi £14,000. In the same year, 47 steam vessels of 89,809 aggregate tonnage entered; India furnished 82·5 % of the total imports, and 70 % of the exports were destined for other Arabian ports. Pearl boats valued at £27,000 were built in 1912–3.

The Interior.—The principal market centres of the interior of Arabia are: Teima and Kheibar (Hejaz), Muhail and Khamis Mushcit (Asir); San'a (Yemen); Makhlaf (Nejran); Lahej (Aden hinterland); Shibam and Hauta (Hadhramaut); Sema'il, Rostaq and Nizwa (Oman); Riyadh, Boreida and Hail (central Arabia); and Hofuf (El Hasa). Trade at these centres consists in the collection of the small surplus native agricultural products and in the distribution of manufactured articles and foodstuffs brought in from the coast.

Communications.—With the exception of the Hejaz line, Arabia was still without railways at the end of 1920. Two extensions of the Hejaz line were projected: (1) Medina–Mecca; (2) Ma'an–Akaba. The first formed part of the original plan—the distance direct being 280 m. and the estimated cost just under £1,000,000. An alternative route, via Rabugh, was also considered and construction was begun at both Medina and Rabugh, but was abandoned. The Ma'an-Akaba scheme did not go beyond the preliminary survey stage. In 1911, a survey of a railway from Mecca to Jidda was made by the Turks, but construction was postponed. In 1909, French engineers surveyed for a railway which the Turkish Government proposed to build from Hodeida to San'a and 'Amran. Alternative routes were considered—one direct via Bajil and Hajla, and the other making a detour through Zebid, Ta'izz and Yerim. As a preliminary, a French syndicate constructed 5–6 m. of metre-gauge track, between Hodeida and a proposed new harbour at Khor el Kethib, about 10 m. to the north. The work and all material and plant (including several locomotives) were destroyed in the Italian bombardment of Hodeida, in 1912. In 1918–9 a metre-gauge military line was extended from Sheikh 'Othman to a few miles beyond Lahej, a total distance of 25 m. from Aden; when not required for military purposes it is available for ordinary transport.

There are no made roads of any considerable length in Arabia, except one of 173 m. from Hodeida to San'a; but sections of certain of the caravan tracks were adapted, during the World War, for rough motor service, *e.g.* the road from Jidda to Mecca and from Akaba to Ma'an. For purposes of trade, the old caravan routes have still to serve. The only route of trans-peninsular character is that from Zobeir to Boreida (379 m.), Mecca (479 m.) and Jidda (55 m.); total, 913 m. For the passage of trade as well as pilgrims, no other caravan route in Arabia compares with it in importance.

The lines of telegraph are: Jidda – Mecca; Jidda – Rabugh – Medina; Hodeida – San'a; Hodeida – Mocha – Sheikh Sa'id; Hodeida – Loheia – Midi; and Mocha – Ta'izz – Yerim – San'a.

For travelling or through-trade purposes the *rafiq* or companion system obtains. Each tribe has a recognized *dira* or range, and in passing from the territory of one tribe to that of another a *rafiq* of the last tribe is absolutely necessary for safe conduct. Inter-tribal trade is also facilitated by the '*Uqeil*, recognized carriers, who are "franked" by all tribes and are thus able to conduct a caravan with more or less security. They are chosen from among the tribesmen of central Arabia and El Hasa, care being taken to exclude members of the more powerful tribes and those who have blood feuds, so as to preserve the neutral character of the organization.

Industries.—Camel-rearing is mostly in the hands of the 'Anaza in the N., the Qahtan and Shammar in the centre, and the 'Ajman and Muteir in the E.; but the herds of the first-named tribe far outnumber those of any other. The centre of the camel trade is in Damascus (where almost all the capital is supplied) and to a less extent in Bagdad. In normal times, the chief tribes are said to possess 720,000 head, but during the World War herds were much depleted. Only the surplus, possibly numbering 45,000 per ann., and those not the best, are sold. A little horse-breeding is carried on by the emir of Nejd and by the Shahran tribes and there is a small export to Mesopotamia and Syria. Considerable numbers of the white, large-boned breeds of asses of El Hasa are sent to Egypt. The fisheries of Arabia, other than pearl, are valuable for the supply of local needs and are capable of development. The salting of fish is an industry at most coast towns, but more particularly those of the Red Sea and Oman; considerable quantities are sent into the interior. During the war operations, some attention was paid incidentally to the study of the Farsan pearl industry and to the possibilities of its development. The rock salt quarries of Salif, opposite Kamaran I., were worked under the control of the Ottoman debt and 105,000 tons of salt were exported to India and the Straits Settlements in 1908. Just prior to the World War an English company was working the quarries; in 1920, operations had ceased for the time being.

ARABI PASHA (*c.*1839–1911), Egyptian soldier and revolutionary leader (*see* 2.283), died at Cairo Sept. 18 1911.

ARBER, EDWARD (1836–1912), English man of letters (*see* 2.323), was killed in a taxicab accident in London Nov. 23 1912.

ARBITRATION AND CONCILIATION [Labour] (*see* 2.331).—Subsequently to 1910, many countries found it necessary to revise their position in regard to arbitration and conciliation in industrial disputes. The growing organization of workers in trade unions which was a marked feature of the last generation rapidly increased as a result of the demand for labour occasioned by the World War; and the feelings aroused by, and the conditions resulting from, the war led to increasing demands on behalf of workers in all countries, which the strong economic position of the workers enabled them to enforce. The war itself in certain instances necessitated exceptional measures in order that the output of munitions of war might not be hindered by strikes and lockouts. Further, the development of industry has been towards more and more specialization and a still closer inter-relation of industry, so that the effects of strikes and lockouts extend far beyond those immediately concerned and may have most disastrous effects on the public. For this reason the state is forced, in the interests of the community, to take cognisance of trade disputes.

United Kingdom

The position in the United Kingdom, at the outbreak of the World War, was that questions affecting rates of wages and conditions of employment were settled normally by discussion between the parties concerned. During the course of half a century, voluntary conciliation boards, standing joint committees or corresponding procedure had been established in all well-organized industries and this procedure was instrumental in settling large numbers of disputes. In certain important industries, *e.g.* agriculture and transport, the workpeople and employers were not sufficiently organized in associations to render such permanent machinery practicable. The statutory powers of intervention in labour disputes held by the Government were derived solely from the Conciliation Act, 1896, an Act framed upon a purely voluntary basis. A connecting link between the activities of the conciliation boards and those of the Government in the settlement of labour disputes was the provision in the regulations governing the procedure of a number of boards for the reference of differences to arbitration under the auspices of the appropriate Government department (since 1916 the Ministry of Labour), and further by the policy of the department in not intervening in a dispute until the parties had exhausted their efforts to bring about an amicable settlement.

During the period immediately following the passing of the Conciliation Act, comparatively little use was made of the procedure of the Act, but the three years immediately preceding the war were years of very marked industrial unrest in the United Kingdom and there was a corresponding increase in the use made of the provisions of the Act. Serious consideration was given by the Government to the question of strengthening their powers in relation to labour disputes, but up to the outbreak of war no steps had been taken to formulate legislative proposals. In this connexion, reference may be made to the report of Sir George (afterwards Lord) Askwith of Dec. 1912, on the Industrial Disputes Investigation Act of Canada (Cd. 6603), and the report of the Industrial Council on Industrial Agreements (Cd. 6952).

Committee on Production.—The needs of the war and the abnormal conditions arising therefrom made both necessary and possible much stronger Government action in regard to stoppages of work. The outburst of patriotic feeling which followed the declaration of war resulted in employers and workpeople voluntarily bringing to a close the existing and pending disputes, but the economic conditions resulting from the war soon produced a fresh series of labour difficulties. In Feb. 1915, the Committee on Production, consisting of Sir George Askwith, Sir Francis Hopwood (Lord Southborough) and Sir George Gibb, representing the Board of Trade, the Admiralty and the War Office respectively, was established by the Government to enquire into and report as to the best steps to be taken "to ensure that the productive power of employees in engineering and ship-building establishments working for Government purposes should be made fully available, so as to meet the needs of the nation in the present emergency." With the establishment of the Ministry of Munitions, the functions of the Committee in relation to production were absorbed by that Ministry; but in the meantime the Committee had developed, as a result of the acceptance by the Government of one of its earlier recommendations on the subject of stoppages of work, into an arbitration tribunal. It had no statutory position until the passing of the first Munitions of War Act in July 1915, but it quickly developed into the principal arbitration tribunal for the settlement of labour disputes and attained remarkable success. In 1917 the

Committee was reorganised, representatives of employers and workpeople being added, to sit with the independent chairman. The Committee ceased to exist at the termination of the war when its place was taken by the Interim Court of Arbitration established under the Wages (Temporary Regulation) Act. During its period of existence, it issued over 3,750 awards covering most of the important industries in the country and dealing with all kinds of questions of wages and working conditions. In particular, reference may be made to the agreements negotiated, first in the engineering and allied trades and later in a large number of other trades, whereby the associations of employers and workpeople agreed to suspend existing agreements for the determination of general wages questions and to refer to the Committee on Production every four months the determination of the question what general alteration of wages, if any, was warranted by the abnormal conditions then existing and due to the war, with further power to determine special district cases.

The next important development after the institution of the Committee on Production in Feb. 1915, was the "Treasury Agreement" on the subject of the acceleration of output on Government work, negotiated between the Government and the principal trade-unions in March 1915. The Government's main proposals embodied in the Agreement were on the one hand to limit profits and on the other to prevent stoppages of work owing to trade disputes, and to secure the suspension during the war of trade-union restrictions on output. Although this agreement marked a definite stage of advance, real progress was not made until the Government embodied their proposals in the Munitions of War Act, 1915. This act was subsequently strengthened by two further Munitions of War Acts in 1916 and 1917.

Munitions Acts.—Under the Munitions of War Acts, a stoppage of work arising out of a difference on or in connexion with munitions work (which expression was given a very wide interpretation as the result of decisions of the High Court) became illegal unless the difference had been reported to the Board of Trade (subsequently to the Ministry of Labour) and had not, within 21 days from the date of the report, been referred for settlement. The compulsory arbitration thus introduced by the Acts was necessarily accompanied by the statutory enforcement of awards issued thereunder. For this purpose the existing forms of arbitration tribunal were utilized, viz. (1) Committee on Production; (2) single arbitrator, selected by agreement between the parties or, failing agreement, appointed by the Board of Trade (subsequently by the Ministry of Labour); and (3) *ad hoc* boards of arbitration, consisting of an independent chairman, an employers' representative and a labour representative. This last form of tribunal had been introduced in 1908 for appointments under the Conciliation Act in order to meet any objection on the part of Labour that, however fair a single arbitrator might be, he could better determine the matters at issue if there were associated with him persons directly acquainted with the point of view of employers and workpeople respectively. The Act of 1915 left it to the option of the Board of Trade to refer any difference reported under the Act to arbitration; the Amending Act of 1916 required the Board of Trade to refer such a difference if satisfied that it was *bona fide*. Although the definition of "munitions work" under the Acts was very wide, it did not include some very important industries such as mining, transport and agriculture, but a further provision of the 1915 Act enabled the parts of the Act relative to the prohibition of strikes and lockouts and compulsory arbitration to be applied to work of any description (in addition to munitions work) by His Majesty by proclamation, and this course was adopted in certain instances (notably, South Wales coal miners, Lancashire card and blowing room operatives, and dockers at London, Liverpool and Glasgow). It may further be noted that the Munitions of War Acts contained no prohibition of incitement to strike. Consideration was given to this aspect of the problem and in Nov. 1915 the Defence of the Realm Regulation No. 42 was amended by the addition of the words in italics as indicated below:—

If any person attempts to cause mutiny, sedition or disaffection among any of His Majesty's forces or among the civilian population, *or to impede or restrict the production, repair or transport of war material or any other work necessary for the prosecution of the war*, he shall be guilty of an offence against these Regulations.

The Acts also authorized the Minister of Munitions *inter alia* to issue orders determining the rates of wages of particular classes of workpeople and a considerable number of orders were issued with regard to the rates of remuneration of women and girls. Other orders which had widespread effects were the orders made in Oct. 1917, giving a bonus of 12½% on earnings to skilled time workers in engineering establishments and in shipyards, with a view to attempting to meet difficulties which had arisen owing to the altered relation between the earnings of skilled time workers and the unskilled and semi-skilled men on piece work. Three special arbitration tribunals were established for the determination of matters arising out of the various orders made under the 1916 and 1917 Acts.

Under the procedure of the Munitions of War Acts, arbitration became the normal method for the settlement of labour disputes. From the point of view of the workpeople, it was more expeditious to claim arbitration under the Acts than to endeavour to secure a settlement by conciliation machinery or other negotiations and, moreover, an award under the Acts was statutorily enforceable. On the employers' side also, arbitration was often found to be the most satisfactory procedure; when so much work was being done for Government purposes, the employers' financial interest in the result of negotiations was diminished. A further development was that in many industries (*e.g.* the railways and coal mines) the conciliation boards fell into abeyance. During the war wages claims were necessarily determined largely in reference to the cost of living and consequently unions made claims for national advances in place of district claims. The net result, therefore, was a very large increase in the number of arbitrations under Government auspices and a falling off in conciliation settlements. During the four years 1915–8, nearly 8,000 awards were issued by arbitration tribunals under the Munitions of War Acts and, to a small extent, under the Conciliation Act, 1896. The Munitions of War Acts also introduced certain other features which have a considerable bearing on the settlement of labour differences, such as the power given to the Minister of Munitions under the Munitions of War Act, 1917, to extend an award, applying to the greater part of an industry, to other firms not party to the award but engaged on the same class of work.

It may be recorded that the New Ministries and Secretaries Act, 1916, transferred the powers of the Board of Trade under the Conciliation Act and the Munitions of War Acts to the newly created Ministry of Labour.

Wages Regulation Act.—Immediately after the Armistice, the Government, at a national conference of employers and workpeople on Nov. 13 1918, intimated that their post-war policy in relation to labour disputes was to leave employers and workpeople to adjust so far as possible their own differences. Certain proposals were placed before the conference for the period of transition while industry was changing over from war to peace conditions. These proposals, which were accepted by the employers and by the trade unions, were embodied in the Wages (Temporary Regulation) Act. The broad principle of that Act was to maintain as minimum rates, for a period of six months, the standard district rates existing at the date of the Armistice. Wages having been regulated during the war mainly in relation to the cost of living, they had at the date of the Armistice reached a level far above the pre-war rate. It was not anticipated that the cost of living would fall considerably immediately after the Armistice, while there was a fear that rapid demobilization might so disturb the labour market as to result in attempts at wage reduction of a kind which would lead to great industrial unrest. The Act repealed the prohibition of strikes and lockouts contained in the Munitions of War Acts, and limited compulsory arbitration to the wage standards dealt with in the new Act; it continued, in the Interim Court of Arbitration, the principle of a central arbitration tribunal which had been so successful in the form of the Committee on Production.

The termination of the war was followed by an outburst of unrest, and the position became so serious that in Feb. 1919, the Government summoned a further national conference of employers and workpeople to consider the position. A committee appointed by the conference subsequently made a number of proposals on questions relating to hours, wages, and general conditions of employment, unemployment and its prevention, and the best methods of promoting coöperation between capital and labour. As regards wages, one of the recommendations was the continuance of the Wages (Temporary Regulation) Act, 1918 for a further period of six months, and this recommendation was adopted by the Government in the Wages (Temporary Regulation) Extension Act, 1919.

In connexion with this period of unrest, special reference may be made to the coal-mining industry where the position became so acute in connexion with demands of the Miners' Federation, including a demand for the nationalization of the industry, that in Feb. 1919 the Government set up a commission (under the Coal Industry Commission Act) to inquire into the position of, and conditions prevailing in, the industry. (For the reports of this commission see Cmd. 359, 360 and 361 of 1919.)

During the war a number of committees and commissions had been appointed by the Government to inquire into problems connected with labour disputes. Thus, there were (1) an inquiry by Lord Balfour of Burleigh and Sir Lynden Macassey, K.C., into "the cause and the circumstances of the apprehended differences affecting munition workers in the Clyde district," Dec. 1915; (2) commission appointed in June 1917 to "inquire into and report upon industrial unrest and to make recommendations to the Government"—reports summarized by Mr. G. N. Barnes, M.P. (Cd. 8696); (3) committee under the chairmanship of Mr. Justice Atkin, appointed in 1918 as a result of a strike of omnibus workers to investigate and report as to the relations which should be maintained between the wages of men and women, having regard to the interests of both, as well as the value of their work (Cd. 835); (4) committee appointed in 1918 under the chairmanship of Mr. Justice McCardie to inquire into matters connected with a strike of munition workers at Coventry and elsewhere in connexion with the Government embargoes on the transfer of employment of skilled men; and (5) committee appointed in Oct. 1916, under the chairmanship of Mr. J. H. Whitley, to make suggestions for securing a permanent improvement in the relations between employers and employed (Cd. 9153, etc.).

Whitley Committee.—The recommendations of the last-named committee were of far-reaching importance and in fact formed the basis of the Government's post-war policy in regard to industrial relations and strikes and lockouts. The committee recommended the setting up of joint industrial councils (now sometimes called "Whitley Councils") in trades where employers and workpeople were sufficiently organized, the extension of trade boards for poorly organized trades, and the temporary establishment of other bodies for "intermediate" trades. The committee's recommendations with regard to the establishment of joint industrial councils were prefaced by a declaration to the effect that in the interests of the community it is vital that after the war coöperation of all classes, established during the war, should continue, more especially with regard to the relations between employers and employed, and that, for securing improvement in the latter, it is essential that any proposals put forward should offer to workpeople the means of attaining improved conditions of employment and a higher standard of comfort generally, and involve the enlistment of their active and continuous coöperation in the promotion of industry. The committee then recommended that H.M. Government should propose without delay to the various associations of employers and employed the establishment for each industry of an organization, representative of employers and workpeople, to have as its object the regular consideration of matters affecting the progress and well-being of the trade from the point of view of all those engaged in it so far as this is consistent with the general interest of the community. The committee recommended that the national councils should be supplemented by the creation of district councils and works committees to deal with district and local matters respectively and they outlined the questions with which the national councils, district councils, or works committees might deal. The Government intimated their acceptance of the recommendations of the Whitley Committee and at this date (Dec. 1920) 63 joint industrial councils have been established in various industries in the country. The Government have applied the machinery in their own industrial establishments and also in the civil service. The committee also issued a report on conciliation and arbitration and their recommendations thereon were as follows:—

(1) Whilst we are opposed to any system of compulsory arbitration, we are in favour of the extension of voluntary machinery for the adjustment of disputes. Where the parties are unable to adjust their differences, we think that there should be means by which an independent inquiry may be made into the facts and circumstances of the dispute and an authoritative announcement made thereon, though we do not think that there should be any compulsory power of delaying strikes and lockouts.

(2) We further recommend that there should be established a standing arbitration council for cases where the parties wish to refer any dispute to arbitration, though it is desirable that single arbitrators should be available where the parties so desire.

The constitution and functions of the joint industrial councils are in many respects similar to those of conciliation boards, but whereas the latter have dealt mainly with questions affecting rates of wages and conditions of labour or demarcation of work between various classes of operatives, the industrial councils are designed to have a wider scope and can take into consideration matters of every kind which appertain to the welfare and smooth working of the industry. The encouragement of joint industrial councils formed a definite part of the broad policy of the Government to encourage industries so far as possible to settle their own disputes. In certain large and important industries (coal-mining, railways, agriculture) where the Government have not yet found it possible to relinquish their special war relations, while joint industrial councils have not been established, the Government have taken steps to set up special conciliation machinery. For example, in coal-mining special machinery is provided for by the Mining Industry Act of 1920; for railways, the Government have established special conciliation machinery, including a national wages board; and in agriculture, wages boards have been established under the Corn Production Act, 1917, and Agriculture Act, 1920. The voluntary conciliation machinery which was the fundamental factor in this country before the war, but which was in suspense during the war, is therefore now being reëstablished on a substantially wider basis and the result of the establishment of the industrial councils has undoubtedly been greatly to increase the opportunities for the conciliatory discussion and adjustment of labour disputes.

The recommendation of the Whitley Committee with regard to trade boards was also adopted by the Government and, following the passing of the Trade Boards Act of 1918, the Government embarked on a policy of the extension of trade boards. These boards differ from Whitley Councils in that they consist partly of representatives of the employers and workpeople in the trade and partly of persons appointed by the Government; their determinations are statutorily enforceable as minimum rates and extend to the whole of the trade and, moreover, the boards are established in industries where the organization of employers and workpeople is weak. While they would not normally be included in the definition of conciliation machinery, it is advisable to note them in connexion therewith as, by establishing minimum rates of wages in low-paid industries, they tend to remove one of the root causes of labour unrest. Moreover, the meetings of employers and employed for trade board business afford opportunities for the mutual discussion of other matters and thus tend to improve the relations between the parties.

Industrial Courts Act.—The recommendations of the Whitley Committee on the subject of conciliation and arbitration formed the basis of the Industrial Courts Act, which was passed in Nov. 1919. This act sets up alternative forms of tribunals to which recourse can be had, if both parties to a dispute agree. Of these,

the principal tribunal is a permanent court of arbitration (called the Industrial Court) consisting of persons appointed by the Minister of Labour, of whom some are independent persons, some are persons representing employers, and some are persons representing workmen; there are also women members. There is a permanent president of the court and in addition there are chairmen of divisions of the court. The other forms of tribunal provided for by the Act are (a) single arbitrators and (b) boards of arbitration consisting of one or more persons nominated by the employers, an equal number nominated by the workpeople, with an independent chairman nominated by the minister. For the purpose of these boards of arbitration, panels of persons (including women) suitable to act in the respective capacities are constituted by the minister. The Industrial Courts Act further empowers the Minister of Labour in the case of disputes, either apprehended or existing, to appoint a court of inquiry, one of the objects of which is to put before the public an impartial account of the merits of the dispute. The Act continued until Sept. 30 1920 the principle of the Wages (Temporary Regulation) Acts, 1918 and 1919, that broadly speaking the wages ruling at the time of the Armistice should remain in force as standard minimum rates. (The Conciliation Act, 1896, continues in existence, but in practice its provisions are covered by the Industrial Courts Act.) The provisions in relation to the appointment of courts of inquiry, for the purpose of making a public inquiry and public report upon the facts and circumstances of a dispute likely to affect seriously the public interest, is based upon the Canadian Industrial Disputes Investigation Act, but while the British Act (like the Canadian Act) provides for the grant to the courts of inquiry of certain compulsory powers to secure the attendance of witnesses, the production of documents, etc., it differs from the Canadian Act inasmuch as it makes no attempt to prohibit a strike or lockout pending the inquiry. The British Act relies entirely upon the value of publicity and the effect of public opinion. In this connexion it may be mentioned that the experience of the working of the Canadian Act has shown that it has failed in practice to prohibit strikes or lockouts and that its success has lain in the power to secure an impartial inquiry and a public pronouncement upon the facts and circumstances of the disputes concerned.

During the first year of the Industrial Courts Act over 500 cases were referred to the arbitration of the industrial court, a number of the cases being of considerable importance as concerning the wage rates of the whole industry. During the same period courts of inquiry were appointed in three instances with satisfactory results.

Compulsory Arbitration.—Certain aspects of conciliation and arbitration procedure in the United Kingdom have aroused special consideration during recent years. From time to time, proposals have been put forward in favour of declaring strikes and lockouts illegal and instituting compulsory arbitration; at trades union congresses, however, resolutions in favour of compulsory arbitration have been defeated by large majorities. Laws on this basis have existed for some time in Australasia and, under the pressure of war conditions, legal prohibition of strikes and lockouts and compulsory arbitration were introduced in the United Kingdom. Success was, however, only partial, and the experience of this period affords no reliable guide as to what might be expected to occur under more normal conditions. A large number of strikes and lockouts, some of considerable magnitude, did in fact occur, and probably the principal influence in restricting the number of stoppages during the war period was the patriotic spirit and the determination on the part of all classes to bring the war to a successful conclusion. The Whitley Committee on the relations between employers and employed came to the following conclusion on this subject:—

We are opposed to any system of compulsory arbitration; there is no reason to believe that such a system is generally desired by employers and employed and, in the absence of such general acceptance, it is obvious that its imposition would lead to unrest. The experience of compulsory arbitration during the war has shown that it is not a successful method of avoiding disputes, and in normal times it would undoubtedly prove even less successful. Disputes can only be avoided by agreement between employers and workers and by giving to the latter the greater measure of interest in the industry, advocated in our former reports; but agreement may naturally include the decision of both parties to refer any specified matter or matters to arbitration, whether this decision is reached before or after a dispute arises.

For the same reason we do not recommend any scheme relating to conciliation which compulsorily prevents strikes or lockouts pending inquiry.

Various Proposals.—Another matter to which considerable attention has been given is the question of the extension to the whole of a trade or industry of the terms of an award or agreement applying to a particular body of employers. In 1913 the Industrial Council under the chairmanship of Sir George Askwith reported that, subject to the agreement fulfilling certain requirements and to an inquiry by the appropriate Government department, an agreement entered into between an association or associations of employers and workpeople covering a considerable part of the trade or district should be made applicable to the whole of the trade or district concerned. The question was considered at trades union congresses in 1912 and 1913 and also by the Labour party in 1913 and was rejected at all these meetings. A recommendation appended to a number of the war agreements for four monthly arbitrations was put into effect by the Munitions of War Act, 1917, which contained a section empowering the Minister of Munitions to extend awards or agreements, if satisfied that they were binding upon the employers employing the majority of the persons engaged on or in connexion with munitions work in any trade or branch of a trade either generally or in a particular district, and a number of orders were issued for this purpose. Under the Wages (Temporary Regulation) Acts, the Minister of Labour had a certain limited power of extending awards and agreements. The report of the provisional joint committee of the industrial conference of 1919 also contained a recommendation for the extension of agreements providing for minimum rates of wages. Proposals with a view to extension were put forward at the time of the introduction of the Industrial Courts Bill, but the conditions which, in the view of the Government, must necessarily be attached to such a proposal, were not acceptable to the workpeople's organizations and accordingly the Industrial Courts Act did not contain any provisions for that purpose. This subject is one upon which there is clearly considerable divergence of opinion.

Another movement to which reference may be made is the proposals which have been put forward from time to time for the setting up of a national joint organization of employers and workpeople to cover all trades. In 1911 an industrial council was established under the chairmanship of Sir George Askwith, consisting of 13 leading representatives of employers and 13 leading representatives of labour from all branches of industry, but save for a report on the extension of industrial agreements, the council did comparatively little work and in due course it lapsed. In connexion with the industrial conference in Feb. 1919, proposals were made for the establishment of a national joint industrial council representative of employers and workpeople, but so far it has not been found practicable to establish such a body. A somewhat similar movement is the proposal, also so far unsuccessful, to establish a national association of joint industrial councils. The lack of success which these proposals have so far achieved would appear to suggest that the highly organized industries prefer to be able to deal independently with their own difficulties and are averse to intervention by outside bodies.

The increased organization of employers and workpeople in the United Kingdom which resulted from war conditions has had substantial effects on the machinery for conciliation and arbitration. Labour realized from its strong economic position the power of combination, but attempts at general strikes after the war have also indicated the limitations of the strike weapon, and in addition have impressed on the trade-union movement the need for coördination. This is having effect in the proposals now under discussion for the establishment of a General Staff for labour. On the other hand, recent strikes have produced in certain quarters demands for the institution of some measure such as a ballot—to be taken in a manner prescribed by statute—prior to a declaration of a strike, but the trade unions are not likely willingly to forego the "lightning

strike." With organization comes the establishment of machinery for the mutual discussion of differences, and discussion often leads to an amicable settlement; on the other hand, with employers and workpeople strongly organized in their respective associations, the claims advanced on behalf of labour develop beyond claims about wages and working conditions, and extend to questions of principle such as labour's right to share in the management and control of industry. Further, when a strike or lockout does occur, it often has far-reaching effects and impresses itself on the mind of the public, who tend to overlook the numerous differences which might have led to stoppages of work, but were adjusted by discussion. It is largely on the ground of the effect on the public that the State is held to be justified in introducing restrictive legislation for dealing with strikes and lockouts, particularly in the group of industries known as "public utility" services, and, failing settlement, of taking exceptional powers such as those conferred on the Government under the Emergency Powers Act, 1920. A further development of organization has been that the larger trade unions appear in some instances to have become over-centralized, and in this connexion the growth of works committees may well be worth watching. Generally it may be said that in recent years there has been in the United Kingdom a very marked increase in the regular meetings of employers and employed for the purpose of discussion of matters which may be at issue between them; and while it cannot yet be said that there is freedom from suspicion and distrust there is clear evidence of the growth of a desire for full and frank discussion of all matters affecting the relations between employers and employed.

The conciliation and arbitration machinery of the British Government is frankly based on the acceptance of organization by employers and workmen into their respective associations; the joint industrial council scheme is based on organization, and the Industrial Courts Act definitely provides that a difference shall not be referred by the Ministry of Labour to arbitration until there has been failure to adjust the difference by the conciliation machinery existing in the industry.

British Colonial Legislation

In connexion with British colonial legislation on the subject of conciliation and arbitration, it may be recorded that in *Canada* the Industrial Disputes Investigation Act of 1907 continues to represent the legislative position of the Government.

In *Australasia* a considerable number of amendments have been made. In New Zealand the Industrial Conciliation and Arbitration Act has been amended to enable awards and agreements to be amended to meet alterations in conditions of employment and the cost of living. Further, the existing machinery was strengthened by the Labour Disputes Investigation Act, 1913, which provides machinery for the investigation of disputes not coming within the scope of the Industrial Conciliation and Arbitration Act. The 1913 Act provides for conference of the parties with a view to securing an amicable settlement, or, in the alternative, investigation by labour disputes committees. Before a strike may lawfully take place, a ballot of the workers is taken by the registrar of industrial unions and the result of the ballot publicly notified. After the lapse of seven days from the publication of such result, the workers are free to strike, whatever the result of the ballot may have been. Similar provisions are made to apply in the case of lockouts. Most of the states of Australia have passed new laws on this subject. In Victoria, under the Factory and Shops Acts of 1915 and 1919, and in Tasmania under the Wages Boards Acts of 1910, 1911, 1913 and 1917, there is a wages board system; in Victoria there is no prohibition of strikes and lockouts, but in Tasmania penalties are provided for stoppages of work on account of any matter in respect of which a board has made a determination. In Western Australia, the Industrial Arbitration Act of 1912 provides for an Industrial Arbitration Court and prohibits strikes and lockouts, while in New South Wales under the Industrial Arbitration Acts of 1912, 1916, 1918 and 1919, in Queensland under the Industrial Arbitration Act of 1916, and in South Australia under the Factory Acts of 1907, 1908, 1910 and 1915 and the Industrial Arbitration Acts of 1912, 1915 and 1916, there are both a wages board and an industrial court system. In accordance with the provisions of the Acts in New South Wales and Queensland, the industrial courts in those states have been exercising the functions of wages boards, and the work of the existing boards has been greatly curtailed. Under the industrial court system, an industry does not technically come under review until a dispute has actually arisen, but most of the Acts have given the president of the court power to summon a compulsory conference. The Commonwealth of Australia has also recently amended its procedure by means of the Industrial Peace Act, 1920, which sets up certain advisory councils (Commonwealth and District) for considering matters affecting the prevention and settlement of trade disputes and further authorizes the governor-general to set up special tribunals (Commonwealth and District) empowered to issue enforceable awards on any industrial disputes (1) referred by the parties to the dispute, or (2) as to which the tribunal or other appropriate authority has convened a compulsory conference and a complete agreement has not been reached.

Other Countries

The movement in the United States is dealt with in a subsequent section of this article. A considerable number of other countries have amended their laws on the subject of the settlement of strikes and lockouts.

In *Norway* a law dated Aug. 1915 introduced for the first time in that country machinery for the settlement of labour disputes by the State. One noteworthy feature of the new measure was the application of the principle of compulsory investigation and delay before a stoppage of work takes place, in which respect it resembles the Canadian Industrial Disputes Investigation Act of 1907. Another noteworthy feature is the compulsory registration of trade unions and employers' associations and the recognition and regulation of collective agreements. Two methods of procedure are established for the prevention and settlement of labour disputes. Questions arising out of existing collective agreements must be brought before a specially constituted labour court, while those originating from other matters affecting labour are to be submitted to conciliation boards to be set up throughout the country. This was followed in 1916 by a compulsory arbitration law. It should also be noted that the Provisional Works Councils Act of July 1920 requires the establishment of a works council in every establishment employing regularly throughout the year not less than 50 workers, on a demand of one-fourth of the workpeople. The functions of the councils are advisory only; they may consider and express an opinion on matters concerning the establishment so far as they relate to working conditions, rates of remuneration, workshop regulations, welfare institutions, etc. No penalty is laid down for failure to comply with the terms of this law.

In *Sweden* the law of 1906 providing for the appointment of conciliators was subjected to inquiry from 1916 onwards with a view to revision and, as a result, it was superseded by three new measures all dated April 1920. The first is a law amending and extending the original law in respect of the appointment of local official conciliators; the second establishes a permanent Arbitration Court (consisting of three impartial persons nominated by the Crown and representatives of organized employers and workpeople) to deal with disputes arising out of collective agreements, without recourse to strikes or lockouts or to legal process in the ordinary courts; whilst the third relates to the appointment, on request, of special arbitrators for individual disputes arising out of collective agreements and involving matters of minor importance. Recourse to the Arbitration Court is voluntary.

In *Rumania* in Aug. 1920 a bill was passed for settling industrial disputes. Strikes and lockouts without recourse to conciliation are prohibited in establishments employing ten or more persons. When a dispute arises, a conference is required to be held in the presence of an official of the Ministry of Labour and if an agreement is reached the decision becomes obligatory on all the parties. Arbitration may be resorted to where conciliation fails and is compulsory in the case of Government establishments and what might be broadly described as "public utility" services. Provision is made for widening the scope of the proceedings and altering the constitution of the Arbitration Court so that the decision may be made applicable to all local establishments similar to those involved in the initial dispute. The decision arrived at is obligatory on all parties.

In *Switzerland* the Factory Act of 1877, which was amended in certain respects in 1905, was repealed and superseded by a new labour law of June 1914, which included within its scope measures for averting and settling industrial disputes. The Act provided, with a view to the amicable settlement of disputes which are calculated to lead to a strike or lockout, for the appointment of permanent cantonal conciliation committees which might intervene either on their own initiative or at the request of the authorities or of the parties directly concerned. Persons summoned before these tribunals are obliged, under penalty, to appear. A certain number of employers and workpeople in any industry may mutually agree to constitute a conciliation committee so far as those employers and workpeople are concerned.

In *Germany* a decree of the new Government of Dec. 1918 continued, for the purpose of the settlement of labour disputes and pending arrangements of further statutory regulations, the system of district conciliation committees which had been established during the war. The constitution, functions and powers of these conciliation committees are similar to those of the industrial courts which have been in existence in Germany for many years, in so far as these latter deal with the settlement of ordinary labour disputes. An Act of Jan. 1920 requires the setting up of works councils, one of whose functions it is to appeal to the conciliation committee or to an arbitration board to be agreed upon, failing a settlement of disputes at the works. It may be noted that these works councils are vested with very wide powers such as the right to demand information of all business transactions. The works councils are to be united in district councils whose work will be coördinated in a federal works council; these can meet representatives of employers in district economic councils and in a federal economic council. A provisional federal economic council has already been established, although the subordinate organizations are not yet in existence. A

bill has been under consideration during 1920 in which it is proposed to make recourse to conciliation compulsory and to make the decisions of the conciliation boards obligatory (a) in public services where they are established by law, and (b) in industries where they exist by reason of a collective agreement; in other cases a strike or lockout may be called in spite of a decision, if a ballot is taken and a two-thirds majority is secured in favour of a stoppage. Meanwhile, as the outcome of a strike of electrical workers in Berlin, a presidential order was issued in Nov. 1920, relative to strikes and lockouts in establishments supplying the community with gas, water or electricity. Under the order lockouts and strikes in such establishments are permissible only after the lapse of three days from the publication of an award by the competent conciliation committee; persons who incite to a strike or lockout, prohibited under the order, or who, for the purpose of bringing about such a strike, perform acts in regard to a workshop, machinery or equipment by which the regular carrying on of the undertaking is hampered or rendered impossible, are liable to imprisonment or a fine—liability to penalty is also incurred by anyone who proclaims a lockout in the circumstances defined; if establishments of the nature indicated are brought entirely or partially to a standstill as a result of a lockout or strike, the Minister of the Interior is empowered to take emergency measures for the maintenance of supplies, including the satisfaction of justifiable demands made by the workers. The cost of putting such measures into operation falls upon the owner of the establishment.

Bibliography.—The principal sources of information are the series of reports and periodicals issued formerly by the Board of Trade and now by the Ministry of Labour, viz.: *Proceedings under the Conciliation Act*, including latterly work done under the Munitions of War Acts, Wages (Temporary Regulation) Acts and the Industrial Courts Act; *Strikes and Lockouts*—these reports contain some particulars of the work of voluntary conciliation and arbitration boards; second *Report on Rules of Voluntary Conciliation and Arbitration Boards and Joint Committees;* fourth *Abstract of Foreign Labour Statistics*. The monthly *Labour Gazette* continues to give valuable information both as to the position in the United Kingdom and abroad; and the information as to the dominions and foreign countries is now supplemented by a new quarterly periodical entitled *Labour Overseas*. Special publications of value are the series of reports of the *Committee* on the *Relations between Employers and Employed*—better known as the "Whitley Committee" (Cd. 9153, etc.); Memoranda issued by the Board of Trade on *Laws in the British Dominions and Foreign Countries affecting strikes and lockouts with special reference to Public Utility Services* (Cd. 6081 of 1912); *Report of Sir George Askwith on the Industrial Disputes Investigation Act of Canada* in Dec. 1912 (Cd. 6603 of 1912); *Report of the Industrial Council of 1913 on Enquiry into Industrial Agreements* (Cd. 6952); and *Reports of the Coal Industry Commission* (Cmd. 359, 360 and 361 of 1919); see also the reports of the various countries, *e.g. New Zealand Official Year Book; Official Year Book of the Commonwealth of Australia; Reports of the United States Department of Labor*, etc. See also Articles on Industrial Councils, Labour Regulation, Strikes and Lockouts, Trade Boards. (H. J. W.)

United States

In the United States the movement for state legislation for voluntary arbitration and conciliation progressed steadily, until in 1920 a majority of states had legislation providing for the settlement of industrial disputes. Many of these states have permanent boards of conciliation and arbitration with two to six members, though three is the usual number. In some states the labour commissioner acts as mediator, while in others a chief mediator is appointed by industrial commissions together with temporary boards of arbitration. Twenty states provide for compulsory investigations, and in several others it is permitted under varying conditions. Twelve provide for the enforcement of an arbitration award when arbitration has been agreed upon by both sides. In 17 states the voluntary agreement to arbitrate must contain a promise to abstain from strikes and lockouts during arbitration proceedings, and two states, Colorado and Kansas, make strikes and lockouts unlawful and a ground for fines and imprisonment. The law of 1915 gives to the Industrial Commission of Colorado the power to compel a hearing in the case of an industrial dispute and to deliver an award which is not mandatory. As in the Canadian Industrial Disputes Act, change of terms of employment, strikes and lockouts are prohibited until after 30 days' notice and until after a hearing and award, if such hearing is started within the time of notice. Though it does not prohibit the right to strike, it delays the strike. Kansas, an agricultural state, by creating, in 1920, a Court of Industrial Relations, established compulsory arbitration. The law applies to industries connected with the manufacture of food products, clothing and wearing apparel in common use; to mining or the production of fuel; to transportation of the above-mentioned articles; and to all public utilities and common carriers, which are declared to be affected with a public interest and subject to supervision by the state. The court, which consists of three judges appointed by the governor for a three-year term, is authorized to summon the parties to a dispute before it, to investigate the conditions of the industry and to make a reasonable award. It may bring suit in the Supreme Court of the state to compel compliance with any of its orders. Either party, if aggrieved by an award, may sue in the state court to compel the Court of Industrial Relations to issue a reasonable order. Though the law recognizes the right of collective bargaining and the right of the individual to quit work, the right of labour to enforce its claims is forbidden. In the case of actual suspension or limitation of the operation of an industry, the court may take it over and operate it during the emergency.

Federal Legislation.—The Federal legislation on mediation and arbitration of 1888 and 1895 applying to common carriers has been superseded by three Acts: the Act of 1913 (the Newlands Act); section 8 of the Act creating the Department of Labor (1913); and title III. of the Transportation Act of 1920. The Newlands Act provided for the appointment of a Federal board for voluntary mediation and conciliation to consist of three members, a Commissioner and two other Government officials, appointed by the President with the advice and consent of the Senate. In four years this board functioned in 71 controversies, 14 of which were settled partly or wholly by arbitration and 52 by mediation. Failure of the Act, however, to meet the railway labour crisis in the fall of 1916 and again in March 1917 resulted in the first instance in Congressional action in the shape of the Adamson law granting the basic eight-hour day to trainmen, and in the second instance in the appointment by the President of a committee from the Council of National Defence to mediate. This meant, in effect, the breakdown of the Newlands Act, though it continued on the statute books subject to the limitation imposed on it by the Transportation Act of 1920. When the Government assumed control of the railways in Dec. 1917, a labour policy was immediately agreed upon. A Railway Wage Board was appointed to make recommendations to the Director-General, and a Division of Labor, headed by a brotherhood (union) official, was created to be the connecting link between employees and officials on the one hand and the Railway Boards of Adjustment. Later a permanent Advisory Board on "Railway Wages and Working Conditions" was created. Successive orders of the Director-General formulated a liberal labour policy, and machinery for handling disputes under these orders was established in the form of three Boards of Adjustment, composed equally of representatives of the administration and the workers. A similar policy was adopted in the Transportation Act of 1920, which makes it the duty of the railways and their employees to "exert every reasonable effort and adopt every available means to avoid any interruption to the operation of any carrier" growing out of any dispute involving grievances, rules or working conditions. In case a dispute arises, it is to be decided, if possible, in mutual conferences of representatives of each side. Disputes that cannot be settled in this way are to go before Railway Boards of Labor Adjustment which may be established by agreement between any road or group of roads and the workers. Except for a stipulation that these boards must contain representatives of organized labour, their size and composition are left to the discretion of the parties concerned. Matters may come before the Adjustment Boards either upon application by the road or the organized workers affected, or upon written petition of a hundred organized workers, or upon the board's own motion or upon the request of the Railroad Labor Board. This last-mentioned board is set up by the Act as the final tribunal for the settlement of railway labour disputes. It is composed of nine members appointed by the President with the advice and consent of the Senate to represent in equal proportion the workers, the employers and the public. During their five-year term of office, members of

the board must not be active members or officers of labour organizations or hold stocks or bonds of any carrier. Disputes may come before the Railroad Labor Board either upon failure of Adjustment Boards or directly. A majority vote is all that is necessary to constitute a decision except on matters taken up directly, in which case one of the members representing the public must concur in the decision. It has power to suspend any decision on wages made by the initial conference if, in its opinion, such a decision involves increases in wages or salaries which would necessitate a substantial readjustment of rates. In such cases the board must, after hearings, affirm or modify the suspended decision, and must also hold hearings on alleged violations of decisions and publish its decisions.

The Act of March 4 1913, creating a Department of Labor, provides that the Secretary of Labor shall have power to act as mediator and to appoint commissioners of conciliation in labour disputes, whenever in his judgment the interests of industrial peace require it to be done. In case mediation fails, arbitration may be proposed by the mediators, who cannot act as arbitrators. During the five years inclusive, 1915–9, the Secretary of Labor took cognizance of 3,644 cases and effected 2,539 adjustments. During 1919 alone 1,780 assignments of commissioners of conciliation resulted in 1,223 adjustments. In addition to the direct efforts of the Secretary of Labor, two other Boards of Labor Adjustment were established as part of the war machinery of the country.

The President's Mediation Commission was appointed in the fall of 1917 to conduct an investigation into the underlying causes of labour unrest which was threatening the output of material needed for war industries and to make specific adjustments. The Secretary of Labor was appointed as Chairman of the Commission. It made investigations in the copper mines of Arizona, the California oil-fields, the Pacific Coast telephone dispute, the unrest in the lumber industry of the north-west, and the packing industry. Settlements were made in all disputes except in the lumber industry, generally after arbitration had failed. In Jan. 1918, the Secretary of Labor upon nomination of representatives of capital and labour appointed a War Labor Conference Board to devise a method of labour adjustment which would be acceptable to employers and workers.

As a result of the Conference Board's report, the National War Labor Board was created by Presidential proclamation in April 1918. The membership consisted of two joint chairmen, five representatives of employees' organizations and five representatives of employers' organizations. As stated in the Proclamation, its powers and duties were "to settle by mediation and conciliation controversies arising between employers and workers in fields of production necessary for the effective conduct of the war, or in other fields of national activity, delays and obstructions in which might, in the opinion of the National Board, affect detrimentally such production" and to provide necessary machinery for these purposes. Its authority did not extend to controversies between employers and workers in any field of industrial or other activity where there was by agreement or by Federal law a means of settlement which had not been invoked. This provision excluded from the jurisdiction of the Board, except by way of appeal, a large group of cases. The ship-building industry had set up by agreement its own Labor Adjustment Board; the Ordnance Department and other producing departments of the Government had created special industrial service sections to consider the complaints of their employees; the coal-mining industry had its labour policy controlled by agreement of all parties with the Fuel Administration and the Government had adopted a separate labour policy for the railways. The statement of principles and policies contained in the report, which governed the decisions and which became an official expression of the Government's labour policy, was as follows: (1) abolition of strikes and lockouts during the war; (2) equal right of employers and workers to organize without discrimination; (3) right of collective bargaining; (4) observance of the *status quo ante bellum* as to union or open shop in a given establishment and as to union standards of wages, hours and other conditions of employment, except that the War Labor Board might grant improvements in labour conditions as the situation warranted; (5) maintenance of established safeguards and regulations for the protection of the health and safety of the workers; (6) payment of equal wages for equal work to women in industry and allotment of tasks proportionate to their strength; (7) recognition of the basic eight-hour day in all cases in which existing laws required it, in other cases settlement of the question of hours with regard to Governmental necessities and the welfare, health and proper comfort of the workers; (8) maintenance of maximum production; (9) regard to be had for labour standards, wage scale and other conditions prevailing in the localities affected, in fixing wages, hours and conditions of labour; (10) right of all workers to a living wage which insures subsistence of the worker and his family in health and reasonable comfort. Provision was made for the settlement where possible by local mediation and conciliation and in event of failure of local machinery, for hearings before the National Board. When the National Board found it impossible to settle the controversy, provision was made for the appointment of an umpire by the National Board or by the President from a panel of disinterested persons. In the enforcements of its awards, the National War Labor Board had no special legal sanction or penalty either to force any party to submit disputes to arbitration or to enforce its awards. So outspoken however was public opinion on the necessity of avoiding interruptions in the war industries and so far-reaching were the wartime powers of the Government over both the employers and workers, that the indirect powers of the Board were sufficient. In only three cases were the Board's awards resisted. In two instances where the employers discriminated against the union employees and refused to abide by the decision in favour of the men, the President was sustained by Congress in taking over the industries. In the case of the strike by the organized workers at Bridgeport, Conn., against the Board's award, the President's threat of unemployment enforced by Governmental agencies compelled the men to return to work.

Besides legislative programmes, the Federal Government has made several other attempts to devise plans for the adjustment of labour disputes. In 1913 President Wilson appointed the Industrial Relations Commission to diagnose the cause of industrial unrest, and in the fall and winter of 1919 he appointed two industrial conferences to formulate a reconstruction labour policy. None of the programmes suggested has been given practical application. Experience during the war demonstrated the possibility of successful Government intervention in industrial disputes through mediation. Even voluntary arbitration was resorted to only in a few instances. Legislation was still needed in 1921 to extend the field of Federal mediation with regard to disputes involving agencies of interstate commerce and disputes so vital and comprehensive in extent that existing state agencies are unable to meet the situation. Though the Secretary of Labor is empowered to intervene in such cases, his intervention introduces political and trade union partizanship, which is objectionable to the parties to the dispute. The rapid increase of state agencies has created the need for coöperation between the state and Federal agencies. (For collective bargaining and arbitration in private industries *see* TRADE UNIONISM.)

ARBUTHNOT, SIR ROBERT KEITH, 4TH BART. (1864–1916), British sailor, was born March 23 1864, and succeeded his father, the 3rd bart., in 1889. He entered the navy in 1877 and was promoted commander 1897, captain 1902 and rear admiral in the 2nd Battle Squadron 1913. Early in the World War he took over the 1st Cruiser Squadron and led it in the battle of Jutland, flying his flag in the "Defence," which was sunk with the loss of all on board May 31 1916.

ARCH, JOSEPH (1826–1919), British labour leader (*see* 2.342), died at Barford, Warwick, Feb. 12 1919.

ARCHAEOLOGY: EGYPT AND WESTERN ASIA.—During 1910–20 advances in Egyptian archaeological knowledge were sure if slow. Of course, generally speaking, less advance was made than in many previous decades, owing to the interregnum caused by the World War, when all British, French, German, and Austrian work was held up, and only the Americans and to a lesser degree the so-called "Egyptian" Service of Antiquities (manned by French and English) did any digging at all; while in all the European countries the energies of all the archaeologists who were not superannuated were transferred to the field of war, and there was no time left to write little papers, still less big books. And several, especially in France and Germany, made the great sacrifice which summarily closed lives and extinguished brains of great value to science. Nevertheless, advance was made.

In the years immediately preceding the war we have to chronicle first a great advance in our knowledge of the beginnings of Egyptian history, owing mainly to the excavations of Prof. Flinders Petrie at Tarkhan [1] and of the German, Prof. Junker (working for Austria), at Tura.[2] Both these places are in Middle Egypt, well N.; the former being near Kafr 'Ammar and the other just S. of Cairo, on the way to Helwan. The point of interest is that their diggings have shown that the Horus kings of Upper Egypt had under the "Scorpion King" (who is not the same person as Narmer or Narmerza, as we now must call him) extended their rule as far as the apex of the Delta, N. of Cairo. The Delta was presumably still independent, and was conquered by Narmerza. A point of importance as to the prehistoric period was scored by the discovery in the same neighbourhood at Gerzeh by Mr. Wainwright of iron beads on a necklace.[3] Now as these beads are admittedly worked metallic iron and must date before 4000 B.C., it is obvious that they are a remarkable confirmation of those who, like the present writer, have in opposition to Prof. Montelius always maintained that iron was known to and occasionally used in a worked state by the Egyptians at a period long anterior to its general introduction and replacing of bronze for weapons and tools.[4] The Old Kingdom finds of iron are now seen to be nothing very extraordinary. But equally it is now impossible to cast any doubt upon them. The oldest iron weapon known was hitherto supposed to be an Egyptian halbert-head of the time of Rameses III., but Mr. Randall MacIver has recently discovered in a tomb of the XII. dynasty at the Second Cataract an iron spearhead which is eight centuries older; dating from about 2000 B.C.[5] Iron was in fact both worked and used sporadically long before the "Iron Age."

Interesting conclusions as to the early ethnology of Egypt have been derived from the systematic examination of the necropolises of Nubia, necessitated by the heightening of the Aswan dam, as a consequence of which the northern portion of the valley S. of the dam became flooded, so that a complete examination of the archaeology of the district had to be carried out in order to save historical evidence from destruction. The results published in the *Archaeological Survey of Nubia* [6] by Messrs. Reisner & Firth have shown that the early culture of Nubia was closely akin to that of the predynastic Egyptians, which no doubt came from the south. After Egypt proper was overrun by the "dynastic Egyptian" people of "Armenoid" stock, who came from Asia and founded the kingdoms of Lower and Upper Egypt, the old barbarous Nilotic culture continued to exist in Nubia. We find an illustration of this in the fact that a red and black pottery, obviously akin to the predynastic Egyptian, but of finer make, was manufactured in Nubia in the time of the XII. dynasty, and introduced into Egypt by Nubian colonists, perhaps soldiers or enslaved prisoners, who preserved also their own native (and really old Egyptian) burial customs, interring their dead in "pan" graves much resembling those of the primitive Egyptians of two and three thousand years before.

Evidence is accumulating, though no completely satisfactory theory can yet be put forward, as to the northern origin of the dynastic Egyptians. Elliot Smith has shown [7] the existence of the two racial stocks in Egypt, the predynastic Nilotic and the invading "Armenoid" from Asia, the man of higher cranial capacity to whom the blossoming of the Egyptian civilization and art out of primitive African barbarism is to be ascribed. This "Armenoid" stock must have come from Asia and, no doubt, reached Egypt by the Isthmus of Suez, but whence it came originally we do not know. Whether it was really Semitic we also do not know: whatever its skull may be its facial type is certainly not Semitic, whether of the fine pure Arab or the coarse big-nosed "Hethitized" types. It is sometimes almost central European in look.

How to equate this foreign civilizing race from Asia with the Semitic elements in the ancient Egyptian speech we do not yet know. It may be that these belong in reality to the old Nilotic inhabitants, who were probably related to the true Semites of Arabia; but the hieroglyphic system seems to have developed in the Delta, and is very probably to be ascribed to the "Armenoids." The Osiris cycle of legends seems to belong to these people. Osiris and Isis are closely connected with Syria and the Lebanon in legend; the *Ded* or sacred pillar of Osiris is doubtless really a representation of a great cedar with its horizontally outspreading branches;[8] another of the sacred Egyptian trees is obviously a cypress; corn and wine are traditionally associated with Osiris, and it is probable that corn and wine were first domesticated in Syria, and came thence with the gods Osiris and Re (the sun god of Heliopolis) into the Delta. Syria in fact is beginning to take shape in our minds as perhaps the most ancient seat of civilization in the world, the common source from which Babylonia and Egypt derived those items of culture in which, in the early period, they resemble one another. It remains for excavation to show whether this hypothesis is or is not correct. And the question whether the "Armenoid" conquerors of Egypt and founders of the kingdoms there, who came from Syria, were Semites still remains unanswered. If they were Semitic speakers, the present facial contours of the northern Semites, which have spread all over the world, are not Semitic at all: for the Egyptian Armenoids in the statues of the Old Kingdom look like Europeans, and must have been of "European" blood.

These new probabilities open up considerable possibilities in research with regard to the relations of the early Minoans and other Aegeans with Syria and Egypt and the undoubted fact of the resemblances of Minoan on the one hand to Syrian and Egyptian religions and funerary practices, and on the other hand to those of the Etruscans.

The facial contours of the modern Jew are predominantly those of the ancient Hittite, who was certainly not a Semite. One has hitherto supposed that he was related to the Mediterraneans, the race to which the Bronze Age Greeks and Italians belonged; but this supposed connexion may well break down in the matter of skull form, as the Hittite skull, like that of the modern Anatolian, probably inclined to be brachycephalic. whereas that of the Mediterranean inclined in the other direction, And now the Bohemian Assyriologist Prof. Hrozný has brought forward evidence[9] that the cuneiform script adopted by the Hittites from the Mesopotamians expressed an Indo-European tongue, nearly akin to Latin! This conclusion is not yet universally accepted, but it seems difficult on the evidence to avoid the conclusion that Prof. Hrozný is right, and if so the curious resemblances of some of the externals of Roman and Hittite religion, and the legendary and other connexions between the Etruscans and Asia Minor, are seen in a new light.

If the Hittites were Aryans, one can hardly suppose a primeval Aryan element in Anatolia. The Indo-Europeans whom we find in Mesopotamia (the Kassites and Mitannians) * and in Palestine about 1400 B.C. can hardly have entered western Asia before 2000 B.C. or thereabouts, and it is probable that the Hittites belonged to the same wandering. On entering

*The fact that the Mitannians venerated Varuna, Indra, and the Asvins is important as showing that Iranian and Indian Aryans had not yet separated as late as 1400 B.C.

Anatolia they probably found the land at least as far W. as the Halys already occupied by Semites. This Semitic population in Anatolia is an important recent discovery. At the time of the great dynasty of Ur (c. 2400 B.C.) in Babylonia, the whole Argaeus region was occupied by these Semites, who seem to have been most kin to the Assyrians. They were no doubt expelled or absorbed by the Hittites, but we have the proof of their existence and of the fallacy of the statement that the Semite never crossed the Taurus, in the cuneiform tablets written in their language which have been found near Kaisariyeh and are now being published by various scholars.[10] No doubt the Hittites learnt the use of cuneiform from these people. Whether the national hieroglyphic system of the Hittites expressed the same Indo-European language as, according to Hrozný, their cuneiform does, we do not know, as further attempts to elucidate it made by Campbell Thompson [11] and Cowley,[12] while in themselves very interesting experiments, do not seem to take us further than previous attempts by Sayce and others. The supposition that the hieroglyphic system belongs to a late age, because it is chiefly found in the 10th and 9th century monuments of Carchemish, is improbable, as it bears all the characteristic marks of Hethitic nationalism, and is evidently a native invention. No people would have abandoned cuneiform for such a clumsy method of writing.

The excavation of Carchemish, lately suspended owing to political uncertainty in Syria, has been very interesting. The palace with its great relief-lined court and its water-gate of Hittite construction, the later Assyrian fortress, and the Hittite tombs with their characteristic pottery, are important results, and the whole work has been one of the major excavations of the last ten years, and has been fitly carried out by the British Museum, under the direction of Dr. Hogarth and Mr. Woolley.[13] The excavations of Dr. Garstang for the university of Liverpool at Sakchegözü,[14] further N., not far from Sinjirli, the seat of earlier German work, have also produced interesting results. The peculiar characteristics of Syro-Hittite art, and its relation to that of Assyria, are matters of great interest to the student of the civilization and art of the Nearer East. Equally interesting are the relation of the Syro-Hittite with the Minoan, and we seem to find in certain objects found in Egypt and Cyprus and dating probably from the 14th to the 10th centuries, proof of the existence of a mixed art of Syrian origin, probably in Cilicia (Alashiya) at that time.[15] Baron Oppenheim's excavations at Tell Halaf have resulted in the recovery of reliefs of barbaric style, simulating the Syro-Hittite, from the palace of a local king, Kapara, of about the same period as Sinjirli and Sakchegözü (10th–9th centuries B.C.), and pottery of all ages, going back to the chalcolithic period.[16]

The neolithic and chalcolithic pottery of Mesopotamia and Persia is one of the chief archaeological discoveries of late years in the Near East, and attention has recently been directed to it again by the important finds at Abu Shahrein (the ancient Eridu) and Tell el 'Obeid, near Ur. The excavations carried out for the British Museum at Shahrein by R. C. Thompson in 1918 [17] and by Hall in 1919, and at El 'Obeid by Hall in the latter year,[18] have shown us that the painted ware of Susa and Musyan, discovered by de Morgan was not confined to Persia, but was the ordinary pottery of Babylonia in the prehistoric (chalcolithic) period. It seems characteristic of the neighbourhood of the gulf; the French excavations at Bandar Bushir [19] on the Persian coast have revealed exactly similar ware. And small finds of it on other sites have shown that it was usual all over Mesopotamia, and connects on the one side with the early pot fabrics of Asia Minor and on the other with the pottery of Anau and the *kurgans* of Turkistan, found by Pumpelly.[20] Its place of origin is not yet known. Rostortzeff in his article drawing attention to the undoubtedly Sumerian or sumerizing "Treasure of Astrabad" [21] in N. Persia (which, it must not be forgotten, may have been an importation from Babylonia and not local art at all), seems to think a northern origin as probable as any other. But as a matter of fact an exclusively Elamite origin is not improbable, from the fact that its earliest and first types are found at Susa. Whether we should deduce from its common occurrence in Babylonia the existence of an Elamite population there in early times, later displaced by the Sumerians, we do not know. Sumerian pottery is different, but there are traces of a transition period. One thing, however, is pretty certain, and that is that the enormous dates B.C. assigned to it by de Morgan and Pumpelly cannot be accepted.

An argument for discontinuity of race is found in the fact that whereas the Sumerians are never represented as using the bow, their predecessors certainly made flint arrowheads. The stone knives, arrowheads, celts, hoe-blades, hammers, nails, awls, etc., associated with this pottery are of kinds which though simple and often crude in type are nevertheless not early, but date from the transition period to the age of metal and the earliest centuries of the latter period. Flint and chert were employed for knives, etc., but with none of the marvellous skill and artistry of the predynastic Egyptian flint-knapper; the early Babylonian used comparatively simple flakes and the wonderful serration of the Egyptian knives was unknown to him though he made the saw-blades. Obsidian and rock crystal were also used for knife making. Celts, of the usual late neolithic type, were generally of green jasper; hoe-blades (looking almost exactly like palaeolithic *haches à main*) of chert or coarse limestone; hammers of granite; mace-heads, of identical type with the early Egyptian, of diorite and limestone; nails of obsidian or smoky quartz, often beautifully made. All these stones were of course imported, as the Babylonian had no stone (except a rough coral rag) at hand as the Egyptian had. And many must have come from far afield. In later days, in the time of the Sargonid kings of Akkad or the monarchs of Ur, stones such as granite, basalt, diorite and dolerite were probably brought from the Sinaitic peninsula, if not from the western desert of Egypt, if the Red Sea coast is to be identified, as seems very probable, with Magan, "the place to which ships went," the land whence the Babylonians got some of their first stones for sculpture and architecture. Magan originally was probably a land on the S. coast of the Persian Gulf, but as the early navigators pushed their voyages further, the ships rounded the coast of Arabia, and came into the Red Sea, and the names of Magan and the neighbouring Melukhkha gradually extended westward, with the result that in late times to the Assyrians Melukhkha meant Ethiopia. Magan, however, probably never meant Egypt proper, the Nile land itself, or Egypt, would have been called *Magan* by the Assyrians in later times; it was called *Musri* then and probably in early times also. So that we are not disposed to accept a recently propounded theory [22] that a certain King Manium of Magan who was overthrown by the Akkadian king Naram-Sin about 2850 B.C., was none other than Menes, the earliest king of Egypt, who is generally identified with Narmerza. "Manium" is a common Semitic name. We need not even suppose that this Manium was a chief of the Egyptian Red Sea coast or even of Sinai. The Magan of which he was king need have been no further afield than the Oman peninsula. And the whole equation seems to break down on the matter of date, as it is quite impossible to bring Narmerza down to 2850 B.C. Naram-Sin was in reality a contemporary of the kings of the V. dynasty.

The question how far connexion was kept up between early Egypt and Babylonia by way of the Red Sea or across the desert is a very interesting one. An important piece of evidence on this point has recently come to light in the shape of the carved hippopotamus-tusk handle of an Egyptian predynastic stone knife, said to have been found in the Wadi el 'Araq, on the right bank of the Nile opposite Nag'Hamadi, and now in the Louvre.[23] On this remarkable object, which is certainly of predynastic Egyptian date (before 3500 B.C.), we see representations of early Egyptians and perhaps other tribes fighting, with ships, some like those represented on the Egyptian predynastic pots and others different, with high prows and sterns, and we also see a strange deity of Babylonian aspect. He is not identical with any known Babylonian deity, but he is the god of a people belonging to the Babylonian culture circle, probably of the inhabitants of the Red Sea littoral. The object is of Egyptian

workmanship, representing this powerful deity of the foreign sea people with whom the predynastic Nilotes no doubt often fought. This, by the way, points to the conclusion that Babylonian (Sumerian) culture and art were considerably older than the Egyptian; but we have no definite evidence yet on this point.[24]

Later points of artistic connexion may be seen when we compare the well-known bronze statues of Pepi I. and his son found at Hierakonpolis by Quibell with the copper lions discovered at Tell el 'Obeid near Ur by Hall two years ago.[25] Dr. Reisner is of opinion that copper was first used in Egypt, and bronze certainly seems to have been used there first. The lions of 'Obeid date from about the Ur-Nina period of Babylonian history, *i.e.* about 3000 B.C. or a century or two earlier; the Pepi statues are two or three centuries later. We see however the similarity of the metal-working of both countries at approximately the same time; both are in the same style of artistic development, the Egyptian perhaps the more advanced of the two, and (if the published analysis by Mosso is to be relied upon) with the additional technique of the alloy with tin, making the metal bronze, and so easier for the heads to be cast. The Sumerians cast the heads of their lions in copper, not always with successful results, and filled them with bitumen and clay (like the image in "Bel and the Dragon," which was "clay within and brass without") to give them solidity. The bodies (or so much of them as ever existed, as only the fore parts remained) were hammered and wrought, like the bodies of the Egyptian figures. The eyes in both cases were inlaid, those of the lions with red jasper, white shell and blue schist: this imitation of the eyes in stone as well as metal figures was a feature common to both arts, which were at this time assuredly not without direct or indirect connexion. Whence the Egyptians and a little later on the Babylonians got their tin for the alloy we do not yet know.

The question as to whether copper really was first used in Egypt is not yet resolved, and many arguments can be brought against the theory of Egyptian origin and in favour of one in Syria or further north.[26]

Egypt has also recently been credited with being the inceptor of the whole "megalithic (or heliolithic, as the fashionable word now is) culture" of mankind, from Britain to China and (literally) Peru or at any rate Mexico via the Pacific Isles.[27] The theory is that the achievements of the Egyptians in great stone architecture at the time of the pyramid-builders so impressed their contemporaries that they were imitated in the surrounding lands, by the Libyans and Syrians, that the fame of them was carried by the Phoenicians further afield, and that early Arab and Indian traders passed on the megalithic idea to Farther India, and thence to Polynesia and so on so that both the teocalli of Teotihuacan and Stonehenge are ultimately derived through cromlechs and dolmens innumerable from the stone pyramid of Saqqara, built by Imhotep, the architect of King Zoser, about 3100 B.C. (afterwards deified as the patron of science and architecture). This theory of Prof. Elliot Smith's is very plausible and "fascinating," but whether it will prove to be true remains to be seen. The Babylonians apparently refused to be impressed by the Egyptians in this matter, and went on building temples in brick, probably for the good reason that they could not get any stone. The only stone building in southern Babylonia is the town wall of Eridu (Abu Shahrein), which is built of rude lumps of a local coral rag.[28] The granites and dolerites from Magan were too fine and too expensive to build with.

Megalithic town walls were naturally common in that stony land, Palestine, and very typical specimens of them were found in the Palestine Exploration Fund's excavations at Bethshemesh ('Ain Shems) directed by Dr. Duncan Mackenzie,[29] whose work also threw new light on the phenomenon of the appearance in Palestine between the 12th and 10th centuries B.C. of sub-Mycenaean (Greek) pottery, which can only be ascribed to the Philistines, whose historical position as a foreign invading force from the Aegean area (Lycia and Crete-Kaphtor) is now entirely vindicated.[30] Another important excavation in Palestine in the period preceding the World War was that of Dr. Reisner at Samaria, which is not yet fully published. Very interesting examples of Israelite written inscriptions on potsherds, dating from the 9th century B.C. and probably from the reign of Ahab, were found that are of great palaeographical importance.[31] Continued work at Samaria should reveal some trace of the civilization of Israel, which we know was considerable, unless the devastation of the Assyrian sieges has destroyed it all. This is possibly the case with regard to the older culture of Canaan in the preceding millennium, of which Palestinian excavations have yielded few traces, though we know it existed.[32] War destroyed it: Palestine was the cockpit of Asia. An interesting discovery seems to have been made in the identification by Drs. Gardiner and Cowley of the earliest Semitic script in the hieroglyphic signs found in Sinai.[33]

Since the war a new British school of archaeology in Jerusalem has been founded under the direction of Prof. Garstang, who has begun for the Palestine Exploration Fund excavations at Ascalon, which have resulted in the discovery of interesting late buildings[34] and this year (1921) in that of a statue of Herod the Great. It is to be hoped that continued work will discover traces of the Philistine period at Ascalon, and relics of the same age will no doubt be discovered at Bethshan (Beisan), for a time the furthest eastward outpost of the Philistines, which is about to be explored by the American School at Jerusalem. The new conditions in Palestine should be very favourable to archaeological work there, and it is to be hoped that in Syria the French will give every facility for international work.

The future of archaeological study in Mesopotamia depends upon the political conditions, which have not hitherto been considered favourable to the resumption of excavation in that country. The great German excavations at Babylon[35] and Assur (Qal'at Sherqat),[36] under the direction of Koldewey and Andrae, will probably not be resumed for many years. They were admirable work, and at Sherqat especially have produced results of the greatest historical and archaeological importance. We now know something of the early history of Assyria and of the succession of Mer kings from monuments found at Sherqat. It is not, however, proposed to give here a list of the newly discovered names[37] of the Babylonian kings on tablets from Nippur, published by Poebel[38] and others, as results of this kind belong to the realm of history rather than to that of archaeology. The new series of "Creation" and "Deluge" tablets from Nippur, published by Poebel & Langdon,[39] also belong to the realm of the historian and anthropologist rather than to that of the archaeologist, so are merely mentioned here; the excavation in which they were found being now ancient history. In Mesopotamia more than any other country literary results have been regarded as archaeology, owing to the enormous mass of the written material recovered, which has caused the study of the art and general civilization of different periods to be neglected in comparison with the same subjects in Egypt.

In Egypt the succession to the work of the *Deutsch-Orient Gesellschaft*, which excavated Babylon and Assur, has fallen to the Egypt Exploration Society, which has taken up the excavation at Tell el Amarna where it was laid down by the Germans at the outbreak of war, after they had recovered from the house-ruins several wonderfully fine examples of the art of the period of Akhenaton, now in Berlin.[40] The first season's labour, under the direction of Prof. T. E. Peet, resulted in interesting discoveries, some of which tend to show that the cult of the Aten or Solardisk was not so rigidly enforced by the heretic king Akhenaton as has been supposed, and that ordinary people were allowed to worship other gods than the sun-disk, at any rate in connexion with funerary ceremonies. The great excavation of the Osireion at Abydos, begun for the Society (then the Egypt Exploration Fund) by Prof. Edouard Naville,[41] but suspended owing to the war, it has not been possible to resume at present, owing to the commitments of the Amarna site and the heavy expense of such work as that at the Osireion, which cannot yet be contemplated. This building, the date of which is not yet finally settled, though its excavator believes it to be of the Old

Kingdom like the temple of the Sphinx at Giza; is one of the most remarkable in Egypt, and the completion of its excavation is much to be desired. For such a work, however, considerable funds are necessary, and all archaeological study has had to struggle along with insufficient means.

Prof. Petrie resumed operations in Middle Egypt after the war, and made interesting discoveries (1921). By the autumn of 1921 conditions for work were improving.

Dr. Reisner, working for Boston, was not held up by the war, but continued his excavations in the Giza pyramid field and in Nubia, making good finds in both places. His determination from the study of their pyramids at Napata (the Barkal region) of the succession of the Ethiopian kings,[42] and his revelations of the colonial dominion of the Egyptians in Nubia under the XII. dynasty, derived from his work at Kerma and Defufa,[43] are of great historical importance.

Other work of importance in Nubia immediately before the war was that of Mr. Randall MacIver and Mr. Woolley for the Eckley B. Coxe (Philadelphia) Expedition,[44] that of Oxford at Farras, directed by Mr. F. U. Griffith,[45] which has resulted in an unrivalled series of Nubian pottery from the earliest to the latest times, and that of Prof. Garstang at Meroë,[46] in the far S., which has shown us a barbaric culture of Egyptian origin, strongly influenced by the Ptolemaic and Roman civilization of its time: this is the culture of the Candaces. The great bronze head of Augustus Caesar, now in the British Museum, is one of the trophies of this excavation, and is very interesting as being either a trophy of war carried off perhaps from Syene, or was actually set up at Meroë by the independent native ruler in honour of the Emperor. Mr. Griffith has added to our knowledge of the ancient languages of the world by his interpretation of the Meroïtic inscriptions,[47] to which Prof. Sayce has also contributed.[48]

Returning to the N. and early times again, we have to chronicle besides Reisner's excavations,[49] those of the university of Pennsylvania (Eckley B. Coxe Expedition),[50] and of Junker for Vienna,[51] all in the pyramid field of Giza. These explorations of the *mastaba* tombs of the III.–VI. dynasties have had interesting results. Among other important archaeological finds of the past decade are those of several new fragments of the "Palermo Stone" and similar annalistic monuments of the V. dynasty,[52] which are of high importance for the early period. The New York Museum has further investigated the Middle Kingdom pyramid field at Lisht and its neighbourhood,[53] and Prof. Petrie and Mr. Brunton have found fine XII. dynasty jewellery at Lahun [54] (now in New York). At Thebes, New York has also carried out work at Qurnet Murra'i and Sheikh 'Abd el Qurna, as well as at Dra' Abul Neqqa and Deir el Bahri,[55] where the Earl of Carnarvon, assisted by Mr. Howard Carter, has also dug with remarkable success, recovering some of the most beautiful relics of the art of the XII. and XVIII. dynasties that we possess.[56] Among other tombs Lord Carnarvon has found the long-sought sepulchre of Amenhotep I.[57] At Thebes important work in the copying of tombs has been done by Mr. and Mrs. de Garis Davies for Dr. A. L. Gardiner, who publishes with them the tombs of Amenemhet and Antefoker, under the auspices of the Egypt Exploration Society.[58] The French Archaeological Institute at Cairo has also excavated Theban tombs [59] and at Dendera a naos of the XI. dynasty, with interesting sculptures of Neb-hepet Re (the king whose tomb temple at Deir el Bahri was excavated by Naville and Hall for the Egypt Exploration Fund in 1903–7) has been found, and taken to Cairo.[60] An interesting discovery of the late period in Upper Egypt, that of images and other temple objects of precious metals, was also made at Dendera by the diggers for natron (sebakh) and recovered by the *Service des Antiquités* for the Cairo Museum.[61]

Outside Egypt proper the work of editing and publishing all the Egyptian inscriptions of Sinai has been begun by Dr. Gardiner and Mr. Peet.[62]

A worthy completion of the record is the wonderful exhibition of all the finest examples of Egyptian art in Britain outside the British and Ashmolean Museums, held by the Burlington Fine Arts' Club in London in the summer of 1921.[63]

ARCHAEOLOGY: GREECE AND GREEK SITES.—All important excavations which were in progress in Greek lands in 1914 came to an end with the beginning of the World War. These had not yet been resumed by 1921, partly because of the increased cost of labour, partly because of the continued inaccessibility of sites. The numerous minor explorations, however, chiefly carried on by Government authorities and local archaeological societies, had been less interrupted. Even the studies of individual members of the foreign schools and institutes had been to some extent continued by these scholars in the course of military service with one or other of the combatant forces in the Near East.

PREHELLENIC PERIOD

The greatest advance during the decade 1910–20 was made in the knowledge of prehistoric Greece, to which increasing interest had been directed since the first discoveries of Sir Arthur Evans in Crete in 1900.

Greek Mainland.—Exploration of the Mycenaean sites of the Greek mainland have shown that beneath the characteristic painted pottery which is so plainly derived from the late Minoan wares,

there is no unbroken sequence of development such as is found at Cnossos and elsewhere in Crete: that is to say, the Mycenaean civilization was not native to Greece proper, but was imposed there in a mature form upon a more backward culture. The earliest Cretan settlements in Greece belong to the end of the third Middle Minoan period, about 1800 B.C. Pre-Mycenaean civilization in Greece varied in different localities. The results of researches on numerous prehistoric mounds in Thessaly were exhaustively published by A. J. B. Wace and M. S. Thompson in 1912. Sites have also been explored in Phocis (Hagia Marina) and Boeotia, in Aetolia (Thermon) and the Ionian Islands, in Attica, at Argos, Mycenae and Tiryns, in the neighbourhood of Corinth, and in the islands of Aegina, Cythera, Euboea, Melos, Paros, and Rhodes.

The results show that Thessaly was free from Cretan or other southern influence until the late Mycenaean period developed in isolation an advanced neolithic culture until the rest of Greece and the Aegean Is. had come almost to the end of their age of bronze. Western Greece appears to have been more barbarous than Thessaly, and its outward connexions, if any, before the Mycenaean period, were with Italy rather than with Greece. South-eastern Greece and the Peloponnesus show (in their sequence of pottery fabrics): (i.) An Early Bronze Age culture (black-varnish ware, *Urfirnis*) similar to that of the Cyclades and Crete but of meaner development, which was dominated in turn by (ii.) its more progressive neighbours of the Cyclades (dull-paint ware, *Mattmalerei*) and perhaps of Asia (Minyan ware), and ultimately (iii.) of Crete (Mycenaean).

For the mainland cultures a new term "Helladic" has lately been invented, and three chronological divisions, Early, Middle and Late Helladic, are proposed to correspond with the parallel Cycladic and Minoan periods. Mycenaean pottery is found to contain elements which do not belong to Crete, but which must be attributed to the influence of the fabrics established in Greece before it. The same development is looked for in Mycenaean architecture. Early Helladic house walls have lately been found by the American School at Corinth (A. W. Blegen, 1921). Prehistoric buildings of the semi-elliptical plan, which previously appeared beneath classical remains at Olympia and at Orchomenos in Boeotia, have now been discovered under the Mycenaean palace of Tiryns, under an Hellenic temple at Thermon in Aetolia and in Levkas.

This new and unexpected knowledge, and modern improvements in the science of excavation, have led to the reëxploration of several old sites. Tiryns was dug again by the German Institute (until 1914), Phylakopi in Melos (1912) and the Kamares Cave in Crete (1913) by the British School at Athens, who also began in 1920 a further excavation on the acropolis of Mycenae. What is chiefly sought by such revision is better evidence for the chronology and inter-relation of the different cultures, but much new information has been gained in regard to plan and structure of the palaces and fortifications of Mycenae and Tiryns. Fragments of painted wall and floor decoration have also been recovered on these sites. Those from Tiryns are a most remarkable series; the figure frescos which have been reconstructed represent women in procession, a chariot group and a boar hunt. A fresco bearing the figure of a woman holding lilies and a vase was also found in the "Palace of Cadmus" at Thebes (1916), where many Early Mycenaean graves were also excavated. Other discoveries at Tiryns were a beehive tomb, perfectly preserved and used throughout the classical period, some pottery vases which bear painted inscriptions in characters said to be derived from the Cretan script, and an accidental find of Mycenaean treasure in 1915 by a labourer employed in the agricultural school. This consisted of bronze swords and vases, gold jewellery with agate and other gems, bracelets, collars, a seal cylinder and two engraved gold rings, one of which, the largest known, bears a religious scene. Mycenaean pottery and a carved steatite vase were found in caves in the island of Cythera in 1915. The Italian occupation of Rhodes in 1911 was followed by a general exploration of the island, in the course of which some graves were opened in the Mycenaean cemetery of Ialysos, which had been dug in 1868–72, and important material is said to have been obtained. This should be useful for establishing the date and classification of the earlier finds, which are in the British Museum. Some Late Mycenaean remains have been found in association with products of the local culture in the Ionian Islands. Doerpfeld sees in the crude settlements in Levkas the works of Homeric Achaeans, and continues to identify the island with Ithaca. A search by rival theorists for evidence which will prove that Cephallenia is Ithaca, has produced nothing more convincing, and efforts to find the city of the Phaeacians at Cape Kephali in Corfù were also unsuccessful.

Crete.—In Crete there were many excavations in progress at the beginning of the war; at Tylissos (by the Greeks), Hagia Triada, Phaistos and Gortyna (Italians), Pachyammos and other sites in eastern Crete (R. B. Seager and the American School). Sir Arthur Evans conducted supplementary excavations at Cnossos in 1912, and the British School reëxamined the Kamares Cave, where the typical Middle Minoan polychrome pottery were first found in Crete, in 1913. During the war only the Greek excavations were continued, and no foreign work has yet begun again (1921). Tylissos was the most productive site. Khatzidakis found there three large houses, each with some twenty rooms and upper storeys, and a unique collection of bronzes, an ingot, some enormous cauldrons, and a statuette of a praying man. This curious figure served to identify a similar but much finer piece of unknown origin, which had lain for many years unrecognized in the British Museum. Another new bronze from Crete had been lately acquired (1921) by an English collector. It represents a man in the act of turning a somersault over the horns of a charging bull, a unique rendering of a familiar theme in Minoan art. Both these pieces were published in the new volume of the *Journal of Hellenic Studies* (1921). The Museum of Fine Arts at Boston also obtained in 1914 a masterpiece surreptitiously excavated and smuggled out of Crete, an exquisite gold and ivory statuette of the snake goddess or her votary.

The Kamares Cave was found to be a sanctuary, not a dwelling, but the offerings consisted almost entirely of pottery of M.M. styles, and there were no specifically votive objects such as other cave sanctuaries have contained. The Italians at H. Triada in 1913 found a portico bordering a courtyard of the palace, a large deposit of inscribed clay tablets, and a well-preserved L.M. III. shrine. Two beehive tombs, said to be Early Minoan, were found near Phaistos. They had been plundered and were destroyed to within a metre of the ground, but still contained some pottery and stone vases, bronze blades, seals, and ivory fragments. At Gortyna the first prehistoric finds of neolithic and Minoan periods were made in 1913. The other discoveries on this site have been nearly all of Roman date. The so-called Odeum, a circular building in which the famous code was found, was completely cleared in 1912, and five small fragments of the inscription were recovered.

Minoan finds were made on several lesser sites: at Plati in the Lasithi Plain in 1914, houses and burials; in eastern Crete at Sphoungaras in 1912, and at Pachyammos in 1914, E.M. to L.M. cemeteries with numerous *pithos* burials, at Damania, in 1915, an L.M. III. tomb of rectangular plan with converging walls closed at the top by a single course of stones. At Gournes, near Cnossos, in 1914 an E.M. cemetery containing hand-made vases of strange fabric was opened by Khatzidakis, who also found in 1911 fragments of *bucchero* cups, in a cave sanctuary at Arkalokhori near Lyttos. Similar grey pottery was found by Xanthondidis in a large E.M. tomb at Pyrgo in 1918. Seager's brilliant discoveries at Mokhlos were published (with coloured plates of the Early Minoan stone vases) in 1912.

"Geometric" Period

Remains of the still problematic transitional period of the Early Iron Age were found in Crete at Atsipada in 1912, and in a settlement at Vrokastro in 1912–3 (R. B. Seager and E. M. Hall). Several sites of the Early Iron Age have also been excavated in Greece, but nothing has been found to prove the origin of the "Geometric" culture, though accumulating evidence still indicates a northern source.

A Geometric cemetery was dug by the Germans at Tiryns, and their finds have been accurately published (1912). Some graves were opened at Eretria in Euboea in 1915. More important are the remains of buildings of this period. A temple built of sun-dried brick and timber has been found at Thebes underlying an archaic temple of Ismenian Apollo and standing on Mycenaean tombs (Keramopoullos, 1916), and a more extensive settlement was found at Thermon in Aetolia (Romaios, 1911–3). This lies similarly underneath an archaic Greek temple of Apollo, which was built apparently in the 7th century to replace the "Geometric" temple, an elliptical structure with an exterior ring of columns. Smaller elliptical houses were found near by, with geometric potsherds, bronzes, and a few iron weapons. Below again are Mycenaean and pre-Mycenaean settlements, with houses built of sticks and mud. The value of the site is its continuity from prehistoric to Hellenic times. The stratification is said to be like that of the settlements at Olympia, but undisturbed.

Halos was added to the number of Early Iron Age sites in Thessaly in 1912 (Wace and Thompson). A tumulus and cist graves were dug containing weapons, fibulae, and pottery of sub-Mycenaean type like that previously found at Theotoku. In Macedonia during the war some finds of the same period were made by British troops on mounds in the Vardar valley, and a cemetery was opened by the Y.M.C.A. at Chauchitsa (Causica) near Lake Doiran. These graves have been further examined since the war, and have yielded material which is said to connect with Thessaly and Hallstatt (S. Casson, 1921). Some bronzes from Chauchitsa are in the Royal Scottish Museum at Edinburgh.

Classical Period

Recent excavations of classical sites in Greece proper have been of minor importance. At Argos, A. Vollgraff continued his researches, but found little besides inscriptions. These are always the most numerous finds on classical Greek sites, and their importance is mainly historical. New inscriptions and the general progress of Greek epigraphy have been minutely recorded from year to year by M. N. Tod in the *Journal of Hellenic Studies*.

Greece.—There has been most archaeological activity at Athens, where its results have been mainly topographical. The cemetery of Kerameikos outside the Dipylon Gate was being extensively excavated and restored, so far as possible, to its original 5th-century appearance by the German Institute in 1914. *Ostraka* inscribed with familiar political names were found in the course of the work. An examination of the Pnyx in 1911 showed that the supporting wall is no earlier than the 4th century. A search for the Odeion of Pericles on the south-east slope of the Acropolis was inconclusive. Some pieces of sculpture were found here, among them fragments of the Parthenon and a singular relief of Asclepius with a kneeling woman suppliant. Sculpture was also found in excavating the Stoa of the Giants and the Roman *agora*. A cemetery at Phaleron dating from the 7th century was examined. A curious find was a grave containing burials of eighteen men fettered with iron collars and shackles. At Sunium the west end, pediment, and roof of the temple of Poseidon was rebuilt with excavated fragments. A circular building identified (by Svoronos) as the Attic mint in the Peloponnesian War, was cleared, and a fine archaic relief of an ephebe crowning himself was discovered. A hoard of about 1,600 silver coins, found at Carditsa in 1914, was acquired by the National Museum of Athens. The coins are chiefly Theban, of all dates down to 315 B.C. There are about 100 archaic Aeginetan staters, and some other rare coins.

The important excavations of the American School at prehistoric sites near Corinth have been mentioned. Work in the city had not been resumed after the war up to 1921; the last finds in 1914 were two colossal portrait statues of members of the Julio-Claudian family, perhaps Gaius and Lucius Caesar. The reëxamination of Delphi by the French School was still going on in 1921, but on a small scale, while the publication of the first discoveries, made in 1892, was still unfinished. Among other details, the interior arrangements of the temple were studied, and it was established that there was no natural cave, but an artificial recess in the sanctuary, of which the walls still remain. The excavator also claimed to have found the *omphalos* itself. The pediment sculptures were reconsidered with fresh fragments and a better knowledge of the *tympanon*, and a new restoration of the eastern group has been proposed (F. Courby, 1914). A popular but scholarly account of Delphi was translated into English from the Danish of F. Poulsen in 1920.

Halae in Locris was dug by Americans in 1911. The cemetery, extending from archaic Greek to Roman times, and the acropolis were explored. The sanctuary of Apollo Corynthos at Longas was excavated in 1911. Five temples were found, and, among small objects, a number of bronzes. Material for reconstructing the *megaron* or Hearth of Despoina was found at Lycosura. The monument was an open-air altar, a terrace with portico, dated about 200 B.C. Many votive terra-cotta statuettes were obtained, the commonest being the figure of a sheep dressed as a woman, erect with a basket on its head, no doubt a ceremonial costume of worshippers. In the Roman city of Nikopolis the temple built by Octavian to Mars and Neptune, in commemoration of the battle of Actium, was excavated in 1912, and fragments of its structure were recovered. Further examination of towers in the town wall of Pagasae (or Demetrias) led to the discovery of many more painted gravestones, like those first found in 1907. The town was explored in 1912, and the cemetery from which the *stelae* came was found. The graves are mostly of the 3rd century B.C. At Tanagra a large series of graves was opened by the Greek authorities in 1911, but the finds, though numerous, were poor. There were more than a hundred terra-cotta statuettes, but none of fine quality.

Thessaly and Macedonia.—Thessaly has been consistently studied by Arbanitopoulos in his capacity as Ephor of Antiquities and as a soldier in the Balkan wars (1912–3). The new territory here and in Macedonia was surveyed as soon as acquired, and a central museum for Thessaly was established in the former Turkish custom-house at Elassona before the cessation of hostilities. The sites of Pella and Dion were examined by the Greeks, and the French began to excavate the necropolis and theatre of Philippi in 1914. In the next war, the landing of the Allied forces at Salonica led to some archaeological discoveries in the occupied territory. Reports of the work of British and French troops were published in the *Annual* of the British School at Athens in 1919. The results were scanty, as would be expected during a military campaign. Prehistoric sites were located on the characteristic mounds of the country, and some were superficially excavated; but most finds were accidental and unrecorded, and many were dispersed and lost. The antiquities collected at the headquarters of the British Salonica force were presented to the nation by the Greek Government, and are now in the British Museum. Shortly before the war a double-chamber tomb was excavated in a tumulus at Langaza. This is the best example of the Macedonian tumulus-tombs, which seem all to be of Hellenistic date. One was excavated by the French in the town of Salonica, and another by the British on the Monastir road in 1919. The Langaza tomb had unusually elaborate architectural ornaments and two pairs of doors, one of wood, the other of marble. The doors were removed to the Ottoman Museum at Constantinople. A series of papers dealing with the little-known antiquities of Thrace has been published by G. Seure in the *Revue Archéologique* since 1911.

South Russia.—The sites of the colonies in South Russia used to be a copious source of Greek antiquities of all periods, but the supply has ceased at the present time. From 1911 to 1914 Kerch (Panticapaion), Old and New Chersonesos, Tanais, Olbia, a town on the Is. of Berezan, and a cemetery on the peninsula of Taman were being excavated. The results were annually reported by A. Pharmakovski in the *Archaeologischer Anzeiger* of the *Jahrbuch* of the German Archaeological Institute. The typical objects from South Russia were jewellery, pottery, terra-cottas, and glass, mostly of florid Greek style. A remarkable glass bowl with coloured reliefs, said to be Alexandrian work, was found at Olbia in 1913. A glass cup with reliefs carved in the blue and white technique of the Portland Vase, representing a pastoral sacrifice, which was sold by auction in Paris in 1912 for 64,000 francs, was said to have come from Heraclea Pontica. The most valuable historical material from the Pontic colonies is archaic Ionian pottery from Berezan. An unusual find was a Scythian royal grave in a tumulus at Solokha, in 1913. The burial was richly furnished with barbaric jewellery, a gold comb, a bow-case and some vases decorated with Graeco-Scythian reliefs. A welcome work on *Scythians and Greeks*, interpreting material which has long lain inaccessible in Russian books and periodicals, was published by E. H. Minns, in 1913.

Greek Islands.—Among the Greek islands Corfù has produced the most notable find. At Goritsa, the ancient Corcyra, in 1911, the Greek Archaeological Society discovered an early archaic temple of Artemis, the excavation of which was continued until 1914 by Doerpfeld at the expense of the former Emperor of Germany. The striking feature of the building is the sculpture of the west pediment, carved in high relief on limestone slabs. The subjects are, between two panthers, a central group of a gigantic Medusa with her two diminutive children, Pegasus and Chrysaor, and corner groups of apparently unconnected battle scenes. A large altar stood before the west front. The small Ionic temple at Kardaki in Corfù was recleared in 1912. The French have made good progress in their work at Delos, where the town site is now said to be a Hellenistic Pompeii, its houses still preserving their mosaic floors and fresco-painted walls. When Mytilene was recovered by the Greeks it was proposed to establish there a central museum for the Aegean islands, except Thasos, and the removal of antiquities was in progress in 1913. The Italian occupation of Rhodes put an end to the important work of the Carlsberg Expedition, and caused the loss of much of the material which had been collected at Lindos by the Danes, but the valuable finds from the archaic town and cemetery at Vroulia were fortunately recorded by K. F. Kinch before their dispersal, and were published in 1914. Greek efforts to recover the Dodecanese led to the publication of a lavishly illustrated book describing the Hellenic antiquities of Rhodes, for the information of the Peace Conference. The Germans began to excavate the great temple of Hera at Samos in 1910. This was a stone building with outer columns of marble, not in the Doric style, as Vitruvius said. It was begun in the 6th century B.C. and never finished. Considerable work was done in Thasos by the French School in 1910 and later. Five gates of the city wall were cleared. They were decorated with archaic reliefs, some of which were previously known. Other important finds were seven statues of women from a sanctuary of Artemis Polo, a temple and altar of Apollo Pythius, decorative terra-cottas from an archaic Prytaneion, a cemetery with carved and painted tombstones, and remains of a triumphal arch of Caracalla.

Asia Minor.—Political conditions in Asia Minor still prevented up to 1921 the reopening of the great city sites. During the war some show of general work was made by members of the German Archaeological Commission with the Turkish forces, but this came to little more than notes on the preservation or destruction of well-known monuments. The French had lately renewed their arrangements for the excavation of Colophon, but no results had been obtained up to 1921 on the site. Very little was done in 1913–4; the "temple of Apollo Clarius" was found to be an exedra and a propylaea, and an oracular grotto of the god was discovered in the hills. It contained potsherds which are said to range from "Troy I." to the Roman period. A small collection of pottery and implements made by H. A. Ormerod during journeys in Pisidia is a useful addition to the scanty prehistoric material from Asia Minor, and shows that the characteristic fabrics of Troy and Yortan extend across the peninsula to Cyprus. A prehistoric settlement was found on Kilik Tepe at Miletus. The last excavations at Ephesus, Miletus and Pergamon produced (besides inscriptions) little more than architectural remains of Hellenistic and Roman date. A report of the work done at Ephesus by the Austrian Archaeological Institute since 1909 was issued in 1913. The results of the German excavations at Miletus after the same year were published in 1911. The enormous temple at Didymi was cleared and all its columns were found to be standing to the height of several metres. The excavation of Miletus was completed in 1914. At Pergamon the Germans cleared two Hellenistic temples, in one of which a broken statue, identified as a portrait of Attalus II., was found. Another volume was added to the lengthy publication of the work at Pergamon.

The most brilliant results in Asia were obtained by American archaeologists at Sardis. Excavations were begun by the Princeton Syrian Expedition (H. C. Butler and W. H. Buckler) in 1910, and were continued actively for five seasons. The city lay between a mountain (its acropolis) and the river Pactolus, and its site was marked by two great Ionic columns standing deep in earth. The

excavators began by driving a level platform from the river bank towards the acropolis on the line of the two columns. They therefore had to deal with a constantly increasing mass of soil, for the mountain has been washed down to the river in a continuous slope. A hundred metres from the columns they struck the west end of a temple, and found that more of the structure was preserved as the covering of soil became deeper. The temple, which (as inscriptions show) was dedicated to Artemis, had been half-buried by a landslip from the acropolis hill in the historic earthquake of 17 A.D. It is a 4th-century Greek building of rich Ionic style, and was still unfinished at the time of the earthquake, then cleared and partially rebuilt, and finally used as a water reservoir in the Byzantine period. At the west end, to which the two standing columns belong, some of the other shafts are still preserved to the height of 30 feet. Great efforts were made to remove the deep deposit of earth from the surrounding precinct, and the temple now stands in a wide, open space; but on its east front, where the cut face of the slope is 50 ft. high, progress was checked by a solid mass of the hill which had come near to wrecking the building altogether, having finished its slide less than 100 ft. from the portico. This mass had buried a great part of the Lydian and Greek cities, but on a protected slope some undisturbed Lydian strata were found. Here the pottery sequence goes back through sub-Mycenaean wares to simpler geometric and plain black and grey fabrics. These provide means for classifying the rich finds from the cemetery which was excavated on the other bank of the river. The tombs, which are chambers cut in tiers in the hard clay of the hillside, were used with few exceptions for repeated burials, and the ejected offerings had been scattered down the slope. Two tumuli were dug in the necropolis of Bin Tepe without result. Great quantities of jewellery were found in the tombs, the gold work said to resemble the Etruscan. Especially noteworthy are numbers of engraved gems in Graeco-Persian (no doubt Lydian) style. These are all of the highest quality. Many bronze mirrors were found. The local pottery is marked in form by a conical base, in technique by a white slip, like the archaic Greek wares of Asia. Some important sculpture was found, and a large number of inscriptions, the most valuable being two bilingual texts, in Lydian-Aramaic and Lydian-Greek. These have not, however, given the key to the Lydian language, nor do they support the theory that Etruscan was derived from Lydian. Annual reports of the excavations were published in the *American Journal of Archaeology.*

Africa.—Next in importance after Sardis among ancient sites explored in 1910–20 is the Greek city of Cyrene, also opened by American enterprise. An expedition, led by R. Norton, made its way there in 1910, but, owing to organized hostility among the natives, its first progress was slow and difficult. In 1911 H. F. de Cou was murdered by hired Arabs, but work was continued until the end of the first season, and before the second season could begin, the country was seized by Italians. The coming of this nation here as in Rhodes put an end to the work of others, and the American excavation has been continued by the Italian Government on a larger scale and with the protection of a military force. The principal finds, as in the earlier British search by R. Murdoch Smith and E. A. Porcher, are Graeco-Roman statues. About twenty had been found up to 1921, among them Zeus with the aegis, Hermes, Alexander as a Dioscurus, Eros stringing a bow, three groups of the Graces, two satyrs, a headless Aphrodite, and a head of Athena found by the Americans. Most of the sculpture decorated a bath restored by Hadrian. The Aphrodite, which is thought to be the finest piece, was removed to the Museo delle Terme in Rome; the rest are at Bengazi.

Some more pieces of Graeco-Roman sculpture have been recovered by the French from the sunken ship off Mahdia. The finest bronzes which had been found before 1910 were published in *Monuments Piot*, vols. xvii., xviii. Among the new finds are a head of Athena, a large statuette of Hermes, and a dog. Archaeological work in Africa met with little or no interruption during the war, either in French or Italian territory. Prisoners of war have indeed done scientific service as labourers on certain sites. But except at Cyrene, the new material from Africa is Punic or Roman, and not Greek.

Sicily and Italy.—In Sicily there has been continuous work on Greek sites at Camarina, Catania, Messina, and Syracuse; the most important results were obtained at Syracuse. There the temple of Athena was excavated by P. Orsi from 1912 to 1917. A pre-Hellenic settlement was found under the temple, marked by incised and painted geometric pottery. This was followed by archaic Greek remains of the early colonists, Asiatic and Protocorinthian pottery, and some carved ivories. Fragments of the temple included a series of terra-cotta architectural ornaments. Among Sicilian discoveries must be counted a remarkable archaic statue of a seated goddess which was in Paris at the outbreak of war, and was soon afterwards acquired by the Berlin Museum.

Researches in South Italy have produced new evidence of the foundation and early relations of the Greek colonies. At Caulonia in 1912 Orsi found prehistoric remains, the Greek city defences, a Doric temple, houses and a cemetery. Here, as elsewhere in Magna Graecia, the architectural terra-cottas are a valuable part of the finds. The sanctuary of Hera Lacinia at Croton was located in 1912. E. Gabrici's extensive researches at Cumae were published in 1913. A temple of Zeus was excavated on a terrace of the acropolis; the great temple of Apollo crowned the summit of the hill. Here, too, the date of the earliest remains goes back before the Hellenic settlement, to the 11th century B.C. In one of three Greek temples excavated at Locri were tiles inscribed in Greek with the name of Clodius Pulcher. A cemetery at Locri yielded large numbers of poor Greek vases, and some exceptionally fine bronze mirrors.

Etruria.—A few mirrors and some Greek vases were found in Etruria at Vignanello in 1913, and from an Etruscan tomb at Todi in 1915 there were obtained some bronzes and more than 70 red-figure vases. The best bronze was a helmet with reliefs on the cheek-pieces; the finest vase an Attic *kylix* signed by Pamphaios. Etruscan antiquities are receiving closer study, but its first results will probably tend more to controversy than to agreement. A paper by F. Weege (in *Jahrbuch*, 1916) on the two most important series of paintings at Corneto argues that these were executed in the archaic style of North Ionia by a Greek artist who had lived among the Etruscans long enough to understand their national life and spirit. To Greeks also we shall perhaps attribute the splendid terra-cotta figures found at Veii in 1916. These had been piously buried near a Roman road. The best preserved is an archaic Apollo, whose arms only are missing. Fragments of other figures indicate that the complete work was a group, not for architectural decoration, representing a contest of Apollo and Heracles about a hind in the presence of Hermes and Artemis. That the archaic art of Etruria was wholly Greek it is hard to believe. It is still equally hard to distinguish Greek work from Etruscan art inspired by Greek models.

(E. J. F.)

ARCHITECTURE (*see* 2.369).—UNITED KINGDOM.—The years 1910–4 were years of great building activity in England. Money was plentiful and only faint rumblings of the impending storm of labour troubles were heard. Many of the recently incorporated municipalities, whose activities were constantly increasing and were hampered by the inadequacy of the old borough council offices to accommodate their increasing staffs, were desirous of obtaining municipal buildings worthy of their civic dignity. The large commercial firms were meditating building new offices of ever-increasing splendour, and the newly enriched, who have always had the ambition to possess land and become county magnates, were planning palatial residences for their newly acquired estates. The war put a stop to all these activities with a suddenness that could hardly have been contemplated. So many years had elapsed since the last great European war that its effects had been forgotten. In fact, opinions were by no means at one as to the effect of war on the arts generally. On the one hand there is no doubt that in the ancient and mediaeval monarchies and republics the arts flourished vigorously during the stirring times when these states were consolidating their power by conquest, some of their finest works having been erected as records in stone of victories over their enemies and their cities having been embellished with

objects of art taken as spoils from the vanquished. On the other hand it may be argued that a lengthy peace, when man's energies lack the outlet which war provides, may tend to turn those energies in quite other directions and cause an outburst of exuberant originality—too often mistaken for genius—in all the arts that almost inevitably leads to such a decadence as is evidenced in "Dada" poetry, futurist and cubist painting and the bizarre extravagances of the late Baroque style of architecture.

But war as waged by the ancients or in fact down to the end of the 19th century was a very different thing from what it is now. In the early part of last century the opinion was growing that war was in course of being modified, softened and civilized, made —as Leigh Hunt says—a thing of courtesy and consideration. Now, however, "frightfulness" is the predominating idea in war. The perfection of modern engineering skill, the enormously increased calibre and range of modern artillery, the conquest of the air as a medium for rapid transport and a fierce velocity of attack never before dreamed of have resulted in a completeness of material devastation that must be seen to be realized. In France alone during the World War 250,000 buildings, including 1,500 schools, 1,200 churches and 377 public buildings, were destroyed so completely that no restoration was possible; while the enormous cost of modern warfare impoverishes all the combatants to such an extent that the spoils which used to go to the victors and be employed in adorning their cities are non-existent.

These are the direct effects of war on the creative arts of man, and the indirect effects are no less harmful. The dragging away from their ordinary peaceful pursuits of all the workers, and the consequent necessity of restricting the output of everything but what is needed for carrying on the war, puts a stop to all constructive effort of an artistic kind. This restriction continues afterwards partly through the scarcity of materials and partly through the demoralization of labour caused by war.

War Buildings.—It seems clear therefore that modern war must have a crippling effect on the arts of peace, especially with regard to architecture. Statistics show that in the first nine months of the year 1914 building plans were submitted for approval to local authorities in England involving an outlay of £12,200,000, whereas in the same period of 1916 the figures were only £5,870,000, out of which as much as £3,000,000 was for temporary workshops and factories for war materials. These buildings, and others of a temporary character for housing the largely increased staff of Government employees—the cost of which in London alone in the year 1916 was £156,000—were practically the only structures which the British Government allowed to be proceeded with during the last three years of the war. In these temporary buildings celerity in construction was the great desideratum, the materials used being of a non-permanent character, such as wood treated with solignum, uralite and asbestos boarding, variety being obtained by breaking the line of frontage and varying the sky line by a judicious alternation of hipped and gabled roofs. In some cases, however, a more elaborate scheme was adopted, involving a carefully planned lay-out and variety in the treatment and grouping of the buildings, which resulted in a picturesque architectural effect. The most important of these special groups of buildings carried out by the Government was at Gretna, where was built the largest explosives factory in the world. Here the factory proper was in two portions separated by an area within which was located the accommodation for the operatives during construction and for the permanent workers. The site chosen for this township—for such it was—providing for about 20,000 inhabitants, was close to the old Gretna Green village, within easy distance of two railway stations, the new accommodation roads linking up with the main road from Carlisle to Glasgow. The buildings comprised no less than five churches, ten schools, three recreation halls, hospitals, cinemas, and fire stations in addition to the houses. The work was carried out under the general direction of Raymond Unwin, assisted by several other architects, and the whole scheme reflects great credit on all who were associated with it.

A similar but smaller building scheme was carried out during the war at Chepstow, where a site of 28 ac. was acquired for the employees of Finch & Co.'s engineering and shipbuilding works. This site offered considerable difficulties in that there was a fall of 88 ft. from one end to the other, but this irregularity has resulted in the creation of a very picturesque village. The houses, which number ten to the acre, are of various sizes planned to meet the requirements of individual families, the walls being constructed of two solid 4-in. blocks of concrete separated by an air cavity of three inches.

Among buildings specially connected with the modern developments of war may be mentioned those for the construction and housing of non-rigid airships. At the commencement of the war Great Britain possessed only six of these buildings, but 61 have been constructed since. Although of no particular architectural interest the large size of these buildings renders them worth a passing notice. Mr. Learmouth states that one of these buildings covers about 8 ac. in area, is 750 ft. long, 130 ft. in height and each bay has a clear roof span of 150 feet.

Post-war Housing.—One of the most interesting developments of post-war building on the part of the British Government was in connexion with land settlement for ex-service men provided for by the Land Settlement (Facilities) Act of 1919. Up to 1914 the various county councils had been empowered to raise local loans for the purpose of providing small holdings under the Small Holdings and Allotments Act of 1908. This work was suspended during the war, and after its termination the Ministry of Agriculture purchased estates and conducted extensive building operations all over the country, the settlement at Sutton Bridge in Lincs. being the most important. The work subsequently devolved on the county councils under the supervision of the Ministry. Between Jan. 1919 and the spring of 1921 upwards of 13,500 small holdings have been erected in England and Wales, consisting of a homestead and farm buildings, involving already an expenditure of over £2,000,000. It was hoped eventually to accommodate over 30,000 settlers. Local materials are used in the construction, and these naturally influence their style. There is naturally not much scope for architectural display, but the planning and aspect of the rooms always receive careful attention. The Ministry placed the supervision of this work in the hands of competent architects under Maj. H. P. Maule.

The cessation of building during the war caused a great shortage of houses, and a large number of housing schemes were started under the Housing Act of 1919 (*see* HOUSING). Garden cities, garden villages and garden suburbs sprang up in all directions. One of the most important features in these new schemes was the limitation of the number of houses to the acre, only twelve being allowed as a rule in urban and eight in rural districts. This is a great improvement on the earlier garden cities, where the close proximity of the houses practically destroys all privacy. It is impossible however to lay out a site on this lavish scale in urban districts where slum property has been demolished and the occupants have to be housed in tenements. In such cases, with three-storey blocks properly separated from one another, perfect hygienic conditions can be obtained, with ample fresh air and sunlight, if there are 60 separate tenements to the acre. Among the rural housing schemes started after the war may be mentioned that near Woolwich carried out by H.M. Office of Works, the Borough of Croydon housing schemes at Norbury, Woodside and Waddon, the Welwyn Garden City, and the interesting village at Burhill, near Walton on the Thames, for aged men and women workers. This was erected in accordance with the provisions of the will of the late William Whiteley, and comprises a village hall, a church and about 300 cottages. Sir Aston Webb, Sir Ernest George, Sir R. Blomfield and other eminent architects collaborated in the scheme.

The urban tenement schemes comprise those at St. Pancras, which were in course of being carried out in 1921, at Islington and St. Marylebone. The much increased cost of building made it very difficult to carry out these schemes on an economic basis.

Churches.—The completion of the interior of Bentley's remarkable Roman Catholic cathedral at Westminster progressed

but slowly during 1910–20. Some of the mosaics of the side chapels had heen finished hy 1921, but very little had heen done with the pavements, for which the architect prepared many beautiful designs worked out with the most meticulous detail both of form and colour; if these designs are eventually carried out the marhle mosaic floor will not suffer in comparison with the best of the older examples.

The Liverpool cathedral by G. Gilbert Scott, which was much delayed during the war, was making fair progress in 1921, and when completed will be a most interesting example of modern Gothic, and from its commanding position, it will be a striking monumental building as seen from the Mersey. That Gothic still holds its own for ecclesiastical buildings is shown by many modern churches, of which St. Mark's, Walsall, by the late Temple Moore, one of the greatest of the modern Gothicists, and a church at Gretna hy Geoffry Lucas, may be taken as types.

Municipal Buildings.—Among municipal buildings the enormous London County Hall on the south side of the river was approaching completion in 1921; the Marylehone town hall by Cooper and the offices of the Metropolitan Water Board by Austen Hall had been completed, and the large building for the Port of London offices occupying a commanding site on Tower Hill was well advanced.

Commercial.—Among recent commercial buildings one of the most noteworthy is the Cunard building at Liverpool hy Willink and Thicknesse. This is one of three important buildings on one of the finest sites in England, with wide spaces all round it, opposite the landing-stage, occupying the position of a small dock that had heen reclaimed from the estuary and was closed in the year 1900. The Italian Renaissance style was adopted for this huilding, the total length of which is 330 ft., and the average breadth 183 ft., the height above the pavement heing 120 feet. The huilding is constructed of reinforced concrete faced with portland stone rock-faced, heavily rusticated and battered up to the first-floor level and with dressed portland stone above, the first and second floors forming a *piano nobile.* A very heavy cornice projecting ahout 7 ft. from the wall face crowns the building and above this is a screen wall about 10 ft. high. It is a matter for regret that there is a lack of harmony in the elevations of the three buildings on this splendid site. Other large commercial London buildings recently completed in 1921 were the Wolseley Motor Car offices in Piccadilly, hy Curtis Green; Australia House in the Strand, by Marshall Mackenzie & Son; and the Kodak huilding in Kingsway, by Sir John Burnet, which in its unadorned severity is an excellent example of the proper way to treat a skeleton steel structure.

Street architecture in the business centre of a town offers to the architect one of the most difficult problems with which he has to deal. It seems almost impossible to disabuse the mind of the ordinary large retail tradesman of the *idée fixe* that the more space he has for outside show of the articles he deals in, the better it is for his business. The consequence is that in most cases the architect has to start his design on the first floor and to all appearances to carry his structure on a thin plate of glass on the ground floor. This is of course fatal to good architecture. Fortunately the idea has been growing—though very slowly—that a more artistic and alluring display of goods can be made if the various articles are framed in panels separated by bold structural piers of stone. Among the best of recent shop fronts in London treated architecturally from top to bottom may he mentioned the Selfridge building in Oxford Street, and Messrs. Heal's premises in Tottenham Court Road. In these buildings the supports of the superstructure are carried down through the ground floor.

The decade 1910–20 saw the commencement of the passing of the Regent Street which had been familiar to Londoners for over a hundred years. Whatever may be thought of stucco design in imitation of stone, there can be no doubt that Nash achieved a really fine effect in the façades of this street, which were dignified, harmonious and free from monotony, and one cannot repress a feeling of regret to see these old fronts replaced by lofty new buildings which, whatever their individual merits may be, do not seem likely to group together so as to give the street an effect of architectural congruity.

Factories.—The effect of their daily surroundings on the workers in factories has heen the suhject of careful attention. Anyone who knows the majority of the old mills and factories in the Manchester district, with their tall brick walls and square windows with no attempt to break their hideous uniformity, cannot but be impressed with the horribly depressing effect which these buildings must have upon those who are employed in them. The planning of factories now demands almost as much care as the design for a hospital. Ample light, preferably from the north, is provided and variegated glazed-brick linings are used for the walls of the work-rooms to break their monotony, the junction of the walls and floors being rounded off to avoid dust accumulating. Mess-rooms and changing-rooms are provided and in these are often placed separate lock-up clothes lockers for each female worker. Employers have begun to recognize the fact that expenditure on these refinements is well repaid by a greatly increased output from the employees.

As another example of the way in which the welfare of employees is cared for may he instanced a building recently erected in Gower Street as a hostel for the female employees of a firm of drapers. Included in this building, which contains about 350 bedrooms, are a lounge, reading-room and library and a large hall with stage for concerts and amateur theatrical performances. This marks an interesting new departure in what may be called domestic commercial buildings.

A considerable amount of discussion has taken place as to the desirability of removing the restriction laid down by the London County Council that no building shall he erected of a greater height than 80 ft. from the pavement, exclusive of two storeys in the roof, and allowing sky-scrapers on the lines of those in New York. Granted the existence of an open space of sufficient extent on all sides, there would be no harm in erecting a huilding 200 or 250 ft. high, hut unfortunately where high huildings are most urgently required is in the congested area of the city and here their erection would result in a complete overshadowing of the lower huildings, which would entirely destroy their amenities and practically render them unusable except hy artificial light. Any general relaxation of the restrictions is to he deprecated, but in exceptional positions there is no doubt that the rules might be modified with advantage.

Domestic.—Domestic architecture, in which England has always excelled, came almost to a standstill during 1910–20, mainly owing to the enormous cost of building. Among recent examples may be mentioned Heath Lodge, Headley Common, by Dawher; a very picturesque house in Avenue Road, St. John's Wood, by Baillie Scott; a house near Goring, a typical example of Ernest Newton's refined work; and a house at Shotton Mill, Surrey, by E. J. May.

Memorials.—War memorials are of various kinds; isolated monuments such as crosses and obelisks; shrines or chantry chapels added to a church; mural tablets; and occasionally what may be called a utilitarian building erected as a memorial but only indirectly associated with those whose deaths are memorialized. The number of these erected all over the United Kingdom as well as in France and Belgium is so great that it is impossible to mention more than a few. Among the isolated monuments the first place must be given to Lutyens's Cenotaph in Whitehall, which, for dignity and simplicity combined, cannot easily be surpassed; the all-India memorial at Delhi (*see* DELHI) by the same architect will he one of the most important features of the new capital of India. Sir R. Blomfield has designed a number of memorial crosses, of which it may be said that the bigger the scale on which they are executed the hetter is their effect. A very graceful example of a memorial cross is one at King's Lynn by O. P. Milne which stands on a large pedestal on the sides of which are engraved in panels the names of those who fell in the war.

The War Memorial Chapel in Ely cathedral by Dawber; the memorial screen and organ designed for Merton College chapel, Oxford, by Sir R. Lorimer, which shows the Gothic tradition still

surviving; the Memorial Gateway at Radley College by Sir T. G. Jackson; the Lifford Memorial Hall at Broadway, the Marlborough College Memorial Hall by Ernest Newton & Sons and the Kitchener Memorial Chapel in St. Paul's cathedral may be instanced as good examples of other types.

Mural tablets do not call for much remark; the chief things to be aimed at in these are good lettering and judicious spacing, many of these tablets being far too crowded. An ornate example of these in cast bronze enriched with precious stones is the Regimental War Memorial to the King's Own Yorkshire Light Infantry in York minster by Voysey.

Architectural Education.—A generation ago no systematized scheme of architectural training existed in England. In Paris an Academy of Architecture was established as long ago as 1671, and there can be little doubt that the excellence of the public buildings all over France in the 18th century was largely due to the supervision which that academy exercised over the training of young architects. The foundation of the École des Beaux Arts in the beginning of the 19th century carried on the work of the academy, and the institution of the Grand Prix de Rome—the blue ribbon of the architectural student, the training for which is spread over from ten to fourteen years and the gaining of which ensured official recognition—offered an incentive to hard work and study which had most beneficial results. In Great Britain until the establishment by the Royal Institute of British Architects in 1887 under Royal Charter of a compulsory examination for all who wished to become members of that body, architectural education was of the most haphazard kind. The new charter empowered the institute to grant certificates and diplomas to those who passed its examinations, and although this policy met with some opposition at first, there can be no doubt that it laid the foundation for systematized architectural education, the full effect of which has only been realized during the last decade. This has been brought about by the increase in the numbers of provincial universities unhampered by old traditions. These bodies, following the lead of similar institutions in the United States, have all recognized the fact that architecture, which is both an art and a science, may fitly be included in the subjects of study for a university degree. In addition to the universities several technical colleges have instituted courses of study in architecture, and there were in 1921 in the United Kingdom ten schools of architecture which were recognized by the Royal Institute and whose certificates exempt those students who gain them from its examinations. These schools are the Architectural Association, London; the universities of London, Liverpool, Sheffield, and Manchester; the Robert Gordon Technical College, Aberdeen; the Technical College, Cardiff; the Heriot Watt College, Edinburgh; and the Glasgow School of Architecture. The university of Cambridge has established a school of architectural studies, but the examination in the subjects comprised in the school curriculum is not associated at present with any diploma; the R.I.B.A., however, exempts certificated students from a certain part of its obligatory examinations.

In Liverpool a special degree in architecture (B. Arch.) has been instituted, but the other universities named include architecture as one of the subjects for an Arts degree. The Liverpool course—which may be taken as a typical one—extends over five years and comprises design in accordance with the methods of the École des Beaux Arts; the history of architecture; physics; geology; sanitation and hygiene; building construction and strength of materials as demonstrated in laboratory tests; specifications, etc. Similar courses slightly varying in detail are given at the other schools. In the university of London (University College) a separate professorship of town planning has been instituted. The Architectural Association, London—which was really the pioneer in architectural education in this country—has a very comprehensive course under a complete staff of lecturers, and the studios and class-rooms in its new premises in Bedford Square are admirably equipped.

All these courses enable the young architect to acquire not only facility in design, but also the special technical knowledge now required in consequence of the development of steel construction, and the fact that so many engineering problems are involved in the erection of any large building; and as all the degree courses involve the passing of a matriculation examination which ensures that the student has first obtained a good general education, one may confidently hope that the reproach so often levelled against architects of a lack of scholarly training is in a fair way of being removed.

Architectural Research.—No record of recent architectural developments would be complete without reference to the researches of Mr. Jay Hambidge of New York on the scale of proportion adopted by the Greeks in the design of their most celebrated temples. These must have been designed on *some* plan, but hitherto all attempts to discover any relation between length and breadth or between the size of the Cella and the whole temple had failed. Mr. Hambidge claims to have established the fact that whereas down to the first quarter of the 6th century B.C. Greek craftsmen used a unit of measurement in which commensurability of line was an essential feature; subsequently a new proportion came into use based on commensurability of area; and this he calls "dynamic" symmetry as opposed to static; in other words geometric and not arithmetic proportion. There is always a danger of a pet theory becoming a sort of Procrustes bed to which facts have to be strained to fit, but Mr. Hambidge has certainly taken great pains to avoid this by having numerous measurements taken independently and checked.

Mr. Hambidge's theory may be described briefly as follows: The diagonal of a right-angled triangle of which one side is unity and the other 2 is $\sqrt{5}$, or 2·236.

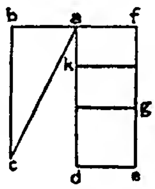

FIG. 1

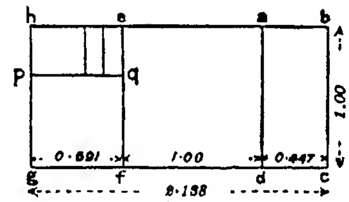

FIG. 2

In fig. 1 $ab=1$, and $bc=2$, so that $ac=\sqrt{5}$; if we make $ad=ac$ and $af=1$ and complete the rectangle $adcf$, this will be a $\sqrt{5}$ rectangle made up of a square dg, and two rectangles gk and kf, each of which is $\sqrt{\frac{5-1}{2}}=0{\cdot}618$. Mr. Hambidge maintains that in the Temple of Apollo at Bassae designed by Ictinus the proportions are based on this rectangle and its multiples and submultiples. In the case of the Parthenon a more elaborate basis is adopted; in fig. 2 $abcd$ is a $\sqrt{5}$ rectangle and if its long side be taken as unity the short side will be 0·447. If to ad the long side of this rectangle we apply a square the side of which is 1 we get a rectangle $ebcf$ of which one side = 1 and the other 1·447. The reciprocal of this latter figure is $\frac{1}{1{\cdot}447}=0{\cdot}691$; and if we apply to ef a rectangle $fehg$ the area of which is 0·691 we shall obtain a large rectangle $hbcg$ the area of which is 2·138, which comprises a rectangle $ebcf$ whose area is 1·447 and a smaller one $efgh$ of area 0·691. This last rectangle is in all respects similar to $ebcf$ and if $gp=gf$ then $fgpq$ will be a square and $hepq$ a $\sqrt{5}$ rectangle. Now whatever we may think of this somewhat elaborate basis of measurement it is remarkable in how many cases the ratios connected with the figures 2·138, 1·447 and 0·691 fit within very small fractions actual measurements of the Parthenon, which, as well as the temple at Bassae, was designed by Ictinus. For example the actual breadth over all of the base of the Parthenon according to Penrose is 111·341 ft. and this figure multiplied by 2·1382 gives 238·069 as the length, the actual measurement so far as can now be ascertained being 238·154, a variation of less than one inch.

Mr. Hambidge has applied this theory to Greek statues and vases with—as he claims—the same results. Those who are interested in the subject may be referred to two papers read before the Royal Institute of British Architects on March 30 1920 and March 5 1921.

The prospect for architectural development in the immediate future was not altogether a bright one in 1921. Although many building schemes both in London and the Provinces were ripe for carrying out, they were kept in abeyance owing to the enormous cost of building and uncertainty as to the action of Labour. Also official architecture was spreading. Large Govern-

ment departments, which used to invite competitive designs for their new buildings with excellent results, were increasingly tending to prepare their own designs. This must lead to a stereotyped style and is not in the best interests of architecture or architects. Design—as far as plan is concerned—has undoubtedly improved immensely, but as to the style which will be adopted for future buildings prophecy would be rash. In 1830 Quartermere de Quincy, in the preface to his *Biographie des plus célèbres Architectes*, uses these words: "*Comme nous ne réconnaissons de véritable art d'architecture que celui qui . . . a dû son origine, ses progrès, ses principes, ses lois, sa théorie et sa pratique aux Grecs . . . nous devons prévenir qu'on ne trouvera dans notre recueil aucune notion d'aucun ouvrage du genre appelé Gothique.*" This seems typical of much modern criticism. The author was surrounded by some of the most beautiful examples of mediaeval art, but ignored them utterly, and yet 25 years later the Gothic revival was in full swing. In 1900 Penrose said that it was impossible to find any one who took the slightest interest in Greek architecture, yet a few years later Neo-Grec and a bastard sort of classic was all the rage in England, while in America many of the finest new buildings are in the purest classic style. Now a free renaissance is in vogue, but how long it will last and what will be its developments no one can tell. The hope is that the complication of modern requirements and the exigencies of modern construction combined with wider knowledge and closer study of ancient examples may lead to the working-out of the great main principles which underlie all the old styles, so as to adapt them to modern necessities without slavish copying of their forms and features. (J. SL.)

UNITED STATES

The Centennial Exposition in Philadelphia (1876) had revealed to a somewhat self-centred and self-satisfied United States the flagrant grossness of its current architecture; the Chicago World's Fair (1893) less than 20 years later disclosed both the possibilities of architecture and the capacity of a new generation of architects. Its influence was widespread so far as the public was concerned, and gave architects themselves new ideals and greater confidence. From 1890 to 1900 the architectural product of the United States was vast in bulk and high in quality. The American Institute of Architects (founded in 1857) broadened its scope and influence, while schools of architecture associated with universities and technical institutes offered wide opportunities for architectural education. The results were evident in the first decade of the 20th century. The Boston Public Library and the Rhode Island State Capitol of McKim, Mead and White were the forerunners and inspiration of many other structures of similar nature and quality, the New York Public Library of Carrère and Hastings and the Minnesota State Capitol of Cass Gilbert being the most notable. In the same category must be ranked many of the club houses of New York, notably the Union and University, as well as sumptuous residences in the larger cities and summer resorts. The Gothic revival, largely determined by Henry Vaughn and Cram, Goodhue and Ferguson, was meanwhile taking to itself practically the whole field of church building and the larger part of college architecture. Beginning with the Episcopal Church, the adoption of Gothic of some English type (usually Perpendicular) extended throughout the Protestant denominations until within 20 years Presbyterians, Congregationalists and Unitarians were also erecting consistent and magnificent Gothic churches. From the work of Cope and Stewardson at Princeton University the same influence spread through the institutions of higher learning, until Tudor or "Collegiate Gothic," as it is called, usurped almost the whole field, though the "McKim Classic" of Columbia and the revived Colonial of Harvard and many of the smaller colleges and schools still maintained themselves as potent forces and in the latter cases a growing force. The rivalry of Classic and Gothic played little part in the two fields of work where American architecture achieved its most vital and original results, the "sky-scraper" and the private house. Steel and reinforced concrete are, as structural elements in buildings, essentially American. Used at first as substitutes or hidden devices clothed with traditional architectural forms, they subsequently developed and established what may be called a "steel frame style." Many daring exponents led the way, including Cass Gilbert, who in the Woolworth Building produced a masterpiece. All the great cities (except Boston which prohibits "sky-scrapers") possess many examples of this brilliant and original work, and in New York in particular there is an extraordinary display of towers.

By 1920, however, there were signs that the vogue of 50-storey buildings was passing, and probably would take its place in history as a brief but sensational episode that brought out some of the most daring exploits, and gave play to the most exuberant fancy, in the architectural record. At the opposite pole stood the domestic architecture of the 20th century. Between 1850 and 1880 this had fallen to the lowest depths, and the influence of H. H. Richardson, distorted after his death by incompetent imitators, was deplorable. Fortunately there came a sudden return to the Colonial models of the 18th century, together with a new study of the domestic buildings of England of the 15th and 16th centuries; and though at first the adaptations were crude and unintelligent, the improvement was rapid, and an extraordinary level of excellence was achieved. No one exerted a wider influence in this direction than Charles A. Platt. So vast was the architectural product of the United States during the first 15 years of the century, that it would be impossible to catalogue the examples of the highest excellence. Among the more distinguished public buildings, in addition to those noted, should be included Henry Bacon's masterly Lincoln Memorial in Washington and B. G. Goodhue's revolutionary design for the Nebraska Capitol. In this field, however, politics were apt to enter with disastrous effects, as for example in the Pennsylvania Capitol. In the work of the national Government there was a serious retrogression during 1910–20, and Government architecture was in grave danger of slipping back to the deplorably low level of the 20 years following the Civil War. Where the political element was eliminated, public architecture achieved a high standard, particularly noticeable in art galleries, libraries and museums. Amongst the first were the Buffalo gallery by Green and Wicks, that at Minneapolis by McKim, Mead and White, and that at Boston by Guy Lowell. One of the most admirable of recent libraries was in Indianapolis, the work of Paul Cret and Zantzinger, Borie and Medary, associate architects, while the Pan-American Building in Washington, by Albert Kelsey and Paul Cret, was an unusual example of vital and personal design. Closely allied were many fine club houses such as the Grand Army Hall in Pittsburgh by Henry Hornbostel, and the Masonic Temple of the Scottish Rite in Washington by John Russell Pope, a building of strikingly noble proportions and majesty of design. In all these buildings classical motives were general, but they were handled with suppleness and originality. Such structures as the Indianapolis library and the Scottish Rite Temple in Washington, D.C., evinced a vital and creative art. Many buildings for universities and colleges, and for schools both public and private, showed equal freedom based on penetrating knowledge of precedents, though the models were almost exclusively English Tudor or American Colonial. Cope and Stewardson initiated the vogue of the former at Princeton, continuing it at Bryn Mawr, Pa., and at Washington University, St. Louis, and it swept over the whole eastern part of the country. Cram, Goodhue, and Ferguson took up the line of development in the vast, fortress-like U.S. Military Academy at West Point and continued it at Princeton in the Graduate College, as well as in other educational institutions, north and south. Day and Klauder gave it new force in the Sage dormitories and freshman dining halls at Princeton, in the new buildings at Cornell University, and at Wellesley College, while James Gamble Rogers contributed the most magnificent exposition of the style in the enormous quadrangle nearing completion in 1920 at Yale. Colonial work achieved notable results at Harvard in the shape of new dormitories by Coolidge and Shattuck, but it was more prevalent in the smaller colleges and preparatory schools, as for instance, Williams College and Phillips Academy, Exeter, where the architects worked

along English Georgian lines in the one case, New England Colonial in the other. With the recovery of the delicate proportions and grave simplicity of the early American style, quite distinct in character from contemporary work in England, this style became almost fixed as the standard type for the eastern states, in public and private schools, a result in great measure due to the influence of E. M. Wheelwright. In the Middle West the Tudor motive, popularized by W. B. Ittner in many public schools, held the field; in the south and on the Pacific coast the early style of the Franciscan missions, sometimes touched by Italian influence, was admirably adapted to modern and local conditions by such architects as the Allisons of Los Angeles; while in Texas, Rice Institute was being worked out by Cram & Ferguson in a curious style with no particular prototype but epitomizing a dozen Mediterranean impulses, the principal effects being attained by combination of coloured marbles and iridescent tiles.

Church building during the period 1910–20 was exceedingly active. Cathedrals, both Roman Catholic and Episcopal, some rivalling in size those of France and England, were building in many places. Amongst the former were the great Byzantine cathedral of St. Louis, Barnett, Haynes and Barnett architects, and that in St. Paul by Paul Masqueray. The Episcopal cathedral, still under way in 1921 in Washington, an immense structure in Decorated Gothic, was designed from the plans which were made by the late George F. Bodley of London, and Henry Vaughn. B. G. Goodhue's Baltimore cathedral promised to be an original and vivid adaptation of English Gothic, while the cathedral of St. John the Divine in New York must, when completed, take rank as the third in size of the cathedrals of the world. Begun in 1891 by Heins and La Farge in a modified Romanesque, it was continued by other architects in an adaptation of the French Gothic of the 13th century, though diverging widely from the standard type. The latter architects also built the bishop's palace, deanery and synod house for the same see, as well as the cathedral in Detroit. The parish churches, both Roman Catholic and Episcopal, were many and generally of high order; it is doubtful if anywhere a loftier standard had been attained. Roman Catholic architecture in the United States, until after 1900, was of a debased quality, even worse perhaps than that of the Protestant denominations. By 1920 such work as that of Maginnis and Walsh in St. Catherine's, Somerville, Mass.; the convent of Notre Dame in Boston, and that of the Carmelites in California; and John T. Comes' churches of St. Agnes, Cleveland, St. Mary's, McKeesport, Pa., and St. Monica's, Rochester, N.Y.; also St. Agnes', Pittsburgh, Pa., restored the balance, a result due almost wholly to these architects. An example of Catholic architecture at its best was B. G. Goodhue's Dominican Church of St. Vincent Ferrer in New York. As for the Episcopal church, St. Thomas's and the Church of the Intercession in New York, both designed by Cram, Goodhue & Ferguson, were indicative of the advance made in the 10 years ending with 1920 toward developing a style which should at the same time preserve the best traditions of Christian art and be mobile in its adaptability to modern times and conditions. Apart from the Christian Scientists, who built widely during the same period and usually in a form of Classic closely allied with that of the standard type of Carnegie library, the Protestant trend has been largely towards Gothic of one sort or another. More and more the new work approached the standards, methods and forms of Catholic art, as for example in Allen and Collens's Congregational church in Newton and the Fourth Presbyterian church in Chicago by Cram, Goodhue and Ferguson and Howard Shaw. Occasionally remarkable re-creations of Colonial work were achieved, chiefly for Congregationalists and Unitarians. The Baptists, Methodists and Lutherans showed only sporadically an inclination towards higher standards, and in the south and south-west decidedly inferior structures were still produced. The Swedenborgians always stood for high architectural ideals and were well served during his lifetime by Prof. Langford Warren. They built at Bryn Athyn, Pa., a "cathedral" which was closely modelled on the lines of the richest type of a large English parish church of the early 15th century. Here for the first time in America the architects (Cram and Ferguson) undertook to put into practice the old "guild" methods of building of the Middle Ages.

With its vast area, its widely varying climatic conditions, its many racial strains, and its groups of independent traditions, the United States has produced as varied an assortment of domestic architecture as might have been expected. Some of the notable palaces of New York and the fine villas set in beautiful gardens and parks in attractive country areas rival the most splendid examples of the Italian, French or English Renaissance, not only in their architecture but in their priceless collections of art of every kind. It is in the more modest dwellings of those not in the multi-millionaire class that recent architecture has scored its greatest triumph. American architects have always been adepts at planning, and American inventors ingenious in devising, new conveniences and luxuries of domestic life. Now that the standard of style has been established and steadily maintained, it may be claimed that the American dwelling equals if it does not surpass all its competitors. The most notable schools of this period were those of Philadelphia, the Middle West, New England and the Pacific coast. The first was initiated by Wilson Ayre, Frank Miles Day and Cope and Stewardson, of whom only the first was alive and working in 1920. But they were followed by a large group of younger men, and the results were striking in originality, consistency and taste. With the local Colonial style as a basis, something was added from the best modern English revival of Tudor architecture, something from the subtle Georgian of Mr. Platt, something from the Italianesque of Mr. McKim, though the dominant note still remained essentially Pennsylvanian. Colour, detail, texture all played their part in a romantic yet honest expression of domesticity, and so universal was its acceptance that even the speculative builder employed the best exponents of this style to develop whole communities along consistent lines. It would be impossible to name all the men who created this significant expression of the best in modern American domestic architecture, but Robert McGoodwin, together with Mellor, Meigs and Howe, Willing and Sims, Edward Gilchrist, and Duhring, Okie and Ziegler, may be mentioned. In the Middle West, there were two tendencies, one with a mathematical basis, the other almost purely poetic. The first seems to have been started by Louis Sullivan, with his strange and vivid motifs in geometrical decoration. Frank Lloyd Wright continued and developed this along extraordinary lines with an exaggeration of horizontal elements that seem to have grown out of decorative forms rather than from material requirements. Claude Bragdon and Pond & Pond also contributed to this movement. The other tendency in the Middle West was best represented by Howard Shaw, and was marked by pure beauty, both in form and detail, measurably Italian yet adapted to local conditions. The New England school was primarily Colonial, for it was in New England that the greatest quantity of this early type of work had been preserved. Its recovery and reconstruction were initiated by Arthur Little, but as in the case of Philadelphia, many younger architects, such as Bigelow and Wadsworth, continued the process. Generically allied with New England was New York, which had many masters of domestic design, if no clearly defined school. Perhaps the most brilliant work, because the most direct, delicate and intrinsically beautiful, was that of Delano and Aldrich, John Russell Pope, and Trowbridge and Ackerman. The school, or schools, of the Pacific coast were at the same time the most baffling and the most stimulating, for strange influences crept in from across the Pacific, mingling with the Spanish traditions of the southern border and yielding alluring results. During the 10 years ending with 1920 the coasts and mountain valleys of southern California blossomed into Persian, Italian and Spanish gardens set with architecture that is so pictorial as to be almost sensational in its appeal, yet with few exceptions it is natural and even naïve. The foundations were laid by Willis Polk, Myron Hunt, Elmer Gray and John Galen Howard, but to them have been added many of a younger generation, especially the Allisons, Robert David Farquhar and Bernard R. Maybeck.

Commercial architecture, hotels, shops, railway stations, *financial and office buildings*, remain to be considered. In view of the vast expansion of American wealth between 1905 and 1920, commercial architecture was of importance, and the standard was of the highest. During this period, thanks to such men as Warren and Wetmore, York and Sawyer, Trowbridge and Livingston, Donn Barber, Robert D. Kohn, John Russell Pope, Starrett and Van Vleck, and to many others, hotels became exhibitions of architectural refinement and good taste, however sumptuous; railway stations became imposing and august monuments (witness the magnificent Grand Central by Warren and Wetmore and the Pennsylvania by McKim, Mead and White, both in New York), while an endless number of shop-fronts and office buildings were delicate and scholarly essays in pure design. Individualism, rampant and uncurbed, largely on the part of the many owners, prevented any approach to unity and consistency in street frontages, but taken each by itself the shop-fronts of Fifth Avenue, in New York, for example, formed an epitome of the best (as well as the earlier worst) to be found in the architecture of America.

The conclusion that must be drawn from a survey of architecture in the United States during the 20th century is that the great regeneration initiated during the eighties of the 19th century went steadily forward until architecture became almost of vital interest to a general public that demanded the best that the profession could give. American architects had an advantage over European in the large demand for their services. Good architecture became the fashion, and this was due largely to three factors: the influence of the American Institute of Architects, the training of the École des Beaux Arts, and the dozen or more great schools of architecture in different parts of the country. Behind this, however, lay the fact that apparently American architects as a whole were drawn from the class that possessed the finest traditions and the soundest standards, and that they were able by sheer force of character and excellence of attainment to impose on the public their own ideals and their own standards of value. The World War was an interlude of non-production, but not, apparently, of non-development, and by 1920 a recovery was being effected, while there was evidently an unfailing supply of younger practitioners to carry on the movement that had already achieved such notable results. (R. A. C.)

ARCTIC REGIONS (*see* 21.938).—The discovery of the North Pole by Peary in 1909 put a check on sensational endeavours, and turned exploration of the Arctic regions along more strictly scientific lines.

Greenland.—The exploration of Greenland has been continued, with few exceptions, by Danes who, besides throwing much light on problems in physical geography and Eskimo ethnography, have practically completed the map of the coasts.

In 1910 Knud Rasmussen founded the station of Thule in North Star Bay, Wolstenholme Sound, as a trading station and a base for researches. On April 6 1912, accompanied by P. Freuchen and two Eskimo, he set out with dog sledges from Inglefield Gulf to cross the inland ice in search of E. Mikkelsen, from whom nothing had been heard for three years. Rasmussen reached the head of Danmark Fjord on May 9, travelled down the fjord and up Independence Fjord to Navy Cliff, which he left on Aug. 8 to return across the inland ice. The greatest alt. in the march across the interior was 7,300 ft. This expedition confirmed by cartographical evidence the non-existence of Peary Channel, a fact established by M. Erichsen in 1907 but not known until his records were brought home in 1912. In order to recover M. Erichsen's lost diaries a small expedition in the sloop "Alabama" went to East Greenland in 1909. After wintering at Shannon I., E. Mikkelsen, the leader, and I. Iversen made a journey of 1,400 m. which in length and difficulty was one of the most remarkable Arctic journeys on record. Their course was over the inland ice to Danmark Fjord, where Erichsen's records were found. These included his discovery that Peary Channel does not exist and Mikkelsen therefore had to abandon his plan of returning *via* the W. coast. After mapping Danmark Fjord he and Iversen returned S. by North-East Cape and the coast, eventually reaching their base, where they had to wait nearly two years for a ship to take them home. In 1912 a Swiss expedition under Dr. A. de Quervain made a successful journey across the southern part of the ice-cap, travelling with the help of dog sledges from Torsukatak Fjord on Disco Bay to Angmagsalik in about 30 days. Their greatest alt. was 8,364 ft.

In 1913 another traverse was made through the heart of Greenland by *Capt. J. P. de Koch, Dr. A. Wegener and a Danish seaman.* After a winter on the E. coast near Danmark Harbour, during which they mapped Louise Land, they left their base on April 20 with ponies to draw their sledges, and reached Lakse Fjord near Proven on Aug. 1. The greatest alt. on the crossing was 9,500 ft.

The second Thule expedition was led by K. Rasmussen in 1916 for the exploration of the N.W. coast of Greenland. Rasmussen was accompanied by Lauge Koch, Dr. Thorild Wulff, H. Olsen and several Eskimo. After an arduous journey of over 700 m. across the ice-cap from Thule, work was started in the neighbourhood of St. George Fjord. Surveys were carried out to De Long Fjord, where they linked up with previous work of Peary. On the return journey Dr. Wulff and Olsen succumbed to the privation of scanty food and bad weather, and the survivors had difficulty in reaching Etah. This expedition found that Nordenskjöld Inlet, the supposed western end of Peary Channel, is only 14 m. long. The inland ice in the N.W. of Greenland was found to extend nearly to the coasts; consequently the hunting grounds are poor and there are few traces of Eskimo migration. Rasmussen considered it very doubtful if Eskimo ever succeeded in reaching the E. coast via the N. of Greenland.

A third Thule expedition started in 1920 under the leadership of Lauge Koch, who proposed to explore the interior of Peary Land and to fill in certain gaps in the chart of the N.W. coast of Greenland. The expedition established its headquarters in Inglefield Gulf, and it was expected to stay in the field until 1922.

The American Crocker Land expedition, from its base at Etah, surveyed part of the coast between Etah and Hall Basin in 1914–5 and made an hydrographic survey of Foulke Fjord. Its principal work, however, was in Ellesmere Land.

The American Crocker Land Expedition.—This expedition was sent in 1913 by the American Geographical Society and other bodies in the United States to search for Crocker Land, which had been reported by Peary in 1906 as lying to the W. of Grant Land.

D. B. MacMillan, the leader, had with him W. E. Ekblaw and M. C. Tanquary, naturalists, and Lt. F. Green, cartographer. Failing to reach either Pim I. or Flager Bay in Ellesmere Land, winter quarters were established at Etah, where a meteorological station was maintained throughout the duration of the expedition. In March 1914 MacMillan and Green crossed Smith Sound on the ice, traversed Ellesmere Land, and, passing by Bay Fjord and Nansen Sound, reached Cape Thomas Hubbard. Thence a journey N.W. over rough sea ice for 150 m. failed to reveal any trace of land, and the party returned to Etah by the same route. The farthest point reached was lat. 82° 30′ N., long. 108° 22′ 30″ W. The members of this expedition made several other long journeys. In 1916 Ekblaw crossed Ellesmere Land from Cape Sabine to Bay Fjord and, passing by Nansen Sound, Greely Fjord and Lake Hazen, reached Fort Conger, Greely's former station on Robeson Channel. He returned to Etah across Kennedy Channel and along the shores of Kane Basin. The same year MacMillan made a long journey to Amund Ringnes I. and Christian I. In 1917 a detailed survey was made of the coast of Ellesmere Land from Cape Sabine to Clarence Head, which considerably altered the charts based on the rough surveys of Inglefield, Kane and Hayes. Several expeditions were sent to relieve the explorers at Etah. The first in 1915 met with an accident, and had to winter in North Star Bay; the second in 1916 failed to get through Melville Bay, but the third in 1917 brought back safely those members of the expedition who had not previously returned *via* the Danish settlements in Greenland.

Beaufort Sea.—Much exploration has been done in and around the Beaufort Sea, although the greater part of that sea is still a blank on our maps.

The ambitious Anglo-American Arctic expedition of 1906–7 achieved relatively little real polar work except a journey from March to May 1907 by E. de K. Leffingwell, E. Mikkelsen, and S. Storkersen from the coast in long. 149° W. across the sea ice to lat. 72° 03′ N., long. 149° 44′ W. where they got a sounding of no bottom in 620 fathoms. V. Stefansson, who was nominally a member of the expedition, spent his time with the Eskimo in the Mackenzie delta, learning their habits and language in order to equip himself for future explorations. During 1908–12 V. Stefansson and R. M. Anderson were studying the Eskimo in and around Victoria I., where they discovered the so-called blonde Eskimo, who had never previously encountered white men. Stefansson's successful explorations must be attributed largely to his methods. He lived in Eskimo fashion using only Eskimo diet, which enabled him to travel light and avoid the necessity of falling back on a base for supplies. Similar methods have been employed with equal success by Rasmussen and other Danes in Greenland.

In July 1913 Stefansson sailed from Nome with a large expedition, supported by the Canadian Government, for the exploration of the Beaufort Sea and the N.W. shores of Arctic Canada. Capt. R. A. Bartlett was in command of the chief ship, the "Karluk,"

and the scientific staff included J. Murray, R. M. Anderson and F. Johansen, naturalists; G. S. Malloch, B. Mamen, and J. J. O'Neill, geologists; H. Beuchat and D. Jenness, anthropologists; W. McKinley and B. M. McConnel, meteorologists; and Dr. Forbes Mackay, surgeon. The "Karluk," with most of the northern party on board, was caught in the ice 20 m. N.E. of Flaxman I. on Aug. 12. The vessel drifted W. until, Sept. 20, when Stefansson and several men were ashore hunting, it broke away during a heavy gale, drifted with the pack until it was crushed, and sank in lat. 72° 8′ N., long. 173° 50′ W., 60 m. N.E. of Herald I., on Jan. 11 1914. All hands and ample stores were got safely on to the ice. After the loss of a reconnoitring party sent south, Bartlett decided to await the return of daylight before making a move, but Murray, Forbes Mackay, Beuchat and a sailor, eager to attempt the journey, set off for the land, with Bartlett's permission but contrary to his advice. They were seen some days later and never heard of again. On March 12 the survivors landed on Wrangell I. and a week later Bartlett, accompanied by an Eskimo and his crew and seven dogs, set out for the mainland, 160 m. across the ice, to seek help. He reached the shores of Siberia in 17 days, and travelling along the coast via Cape North, reached Emma Harbour, whence he crossed in a whaler to St. Michael. The "King and Wing" rescued the survivors on Wrangell I., and the "Bear" brought them to Nome. Malloch, Mamen and another man had died on the island. The remainder of the expedition, employing several small sloops, did a great deal of useful work. Stefansson, with two companions and a dog team, left Martin Point, Alaska, on March 22 1914, reached lat. 73° N., long. 140° W., and then turned E. to Banks I., landing near Cape Prince Alfred on June 26 and joining his vessel at Cape Kellett. In Feb. 1915 with three companions, Stefansson reached Prince Patrick I., and completed the charting of the coasts. Pushing on he discovered a new island in Gustav Adolf Sea. In 1916 he reached this island, and discovered a second smaller island N. of Ellef Ringnes I. and a third, also small, E. of the first and N. of Melville Island. Ellef Ringnes I. was found to be two islands, and Christian I. was found to be much smaller than had been supposed. Much survey work was also done in Banks I., Victoria I. and the coasts of Dolphin and Union Straits. In 1918 a severe attack of fever compelled Stefansson to hand over the command for the last season's work to S. Storkersen. Storkersen, setting out from Cross I. on the coast of Alaska, travelled over the sea ice to lat. 73° 58′ N., long. 147° 50′ W. and then returned to the mainland. This journey practically removed from the map the doubtful Keenan Land (reported vaguely in the 'seventies of last century), while soundings taken during the drift of the "Karluk" and other journeys of the expedition show a narrow continental shelf, and reduce the probability of land existing in the western part of the Beaufort Sea. On the other hand a sounding of only 275 fathoms, about 100 m. N.W. of Isachsen I., indicates the possible occurrence of land in the eastern part of that sea, although Crocker Land has turned out to be a myth. Stefansson's expedition also brought back many observations in anthropology and geology.

Russian Expeditions.—Several ambitious but ill-equipped Russian expeditions sailed for Arctic regions in 1912, but came to grief and accomplished little or nothing. G. L. Sedoff hoped to make Franz Josef Land a base for a march to the Pole. He left Archangel in the "Phoca" and wintered at the Pankratiev Is. in the N. of Novaya Zemlya. Next summer the "Phoca" (rechristened the "Suvorin") reached Hooker I., Franz Josef Land. Sedoff set out for the Pole with two companions and 24 dogs. On the death of the leader in the vicinity of Rudolf I. the journey was abandoned. G. L. Brusilov sailed in July 1912 to attempt the north-east passage in the "Santa Anna." The vessel was beset in the ice in the Kara Sea in lat. 71° N. and drifted a year and a half to the vicinity of Franz Josef Land. Eleven men left the ship in April 1914 in lat. 83° N., long. 63° E. Two of these reached Cape Flora, where the "Phoca" found them: the others perished on the way. Nothing has since been heard of the ship and the remainder of its crew. V. A. Rusanov in the "Hercules" was last heard of in 1912 in Matochkin Shar on his way to the Kara Sea on a voyage of exploration. The Russian Government in 1914 sent the "Eclipse" under Otto Sverdrup to search for Brusilov and Rusanov. Sverdrup passed through the Kara Sea searching the coast eastward to Taimir Land where he wintered in lat. 74° 45′ N., long. 92° E. He was able to be of some service to Vilkitski's expedition wintering about 180 m. to the east, but returned to Archangel in Sept. 1915 without having found any trace of the missing expeditions.

Russian efforts to explore the N. coast of Asia in ice-breakers were far more successful, but unfortunately there is every likelihood of the detailed observations which were sent to the Ministry of Marine having been lost. The "Taimir" and "Valgach," which Capt. Sergiev had taken from Petropavlovsk to near Cape Chelyuskin the previous Sept., left Anadir in July 1913 under Comm. B. A. Vilkitski and Comm. P. A. Novopashennoi for an hydrographic survey of the Arctic coast of Siberia. After charting Chaun Bay the vessels separated, the "Vaigach" following the coast westward and the "Taimir" turning N. for the New Siberia Islands. A small new island was discovered E. of this group and named General Vilkitski Island. Bennett I. was found to be much smaller than had been supposed, and no sign of Sannikov Land (reported on more than one occasion to have been seen from Kotelnoi, New Siberia I.) was discovered on the route to Taimir Land. Here the two vessels met, and continued the coast survey. New land was discovered N.W. of Cape Chelyuskin. Nikolas Land extends from lat. 77° 50′ N., long. 99° E., to at least lat. 81° N. It was surveyed on the east, where a landing was made in lat. 80° 04′ N. The land rises to 1,500 ft., is heavily glaciated, and in geological structure is similar to the mainland. Between Nikolas Land and the mainland two islands were discovered and named Alexis and Starokadomski, each with a greatest width of about 6 miles. The existence of these lands helps to account for the usual obstruction of pack-ice in the waters of the Nordenskjöld Archipelago and the Kara Sea. The vessels being prevented by ice from going farther westward, returned eastward along the N. of the New Siberia Is. to Koliuchin Bay (Sept. 29) and back to Vladivostok. In July 1914 Vilkitski set out again with the same vessels. Ice prevented a search of Wrangell I. for Stefansson's men. A new island was discovered in lat. 76° 10′ N., long. 153° E., and surveyed. The vessels passed N. of the New Siberia Is., again seeing no sign of Sannikov Land, and reached Cape Chelyuskin late in August. Some further surveys of Nikolas Land were made, but ice conditions were bad. Attempts to push westward failed, and by the middle of Sept. winter quarters were found about 100 m. W. of Cape Chelyuskin, the "Taimir" in lat. 76° 41′ N., long. 100° 50′ E. and the "Vaigach" in lat. 76° 54′ N., long. 100° 13′ E. The vessels got clear of the ice, and proceeded early in Aug., passed through the Kara Sea without encountering ice, and reached Archangel in Sept. 1915.

Roald Amundsen.—The long-deferred expedition of Roald Amundsen to the polar basin left Norway in June 1918 in the "Maud," built on an improved model of the "Fram."

The first winter was passed near Cape Chelyuskin. From there two men were sent home with dispatches *via* Siberia, but have not been heard of again. In Sept. 1919 the "Maud" continued her voyage through the ice-encumbered Nordenskjöld Sea and Laptev Strait. East of the New Siberia Is. Amundsen pushed his vessel into the pack in order to begin his drift across the Arctic Ocean, but on finding that the current was setting S. he abandoned the attempt for the year, and sought winter quarters at Aion I., Chaun Bay. In July 1920 he arrived at Nome in Alaska having completed the north-east passage. Soon after he left for the north to resume his original plan. The "Maud" may be expected to emerge between Greenland and Spitsbergen not later than 1923. The Norwegian Government has arranged for depots of food to be laid on the N. coasts of Greenland and Grant Land. The work was done in 1920 by the Dane, G. Hansen.

See also the article SPITSBERGEN.

Claims to Sovereignty.—During the last ten years practically all unclaimed Arctic lands have come under the sovereignty of one or other State. The treaty transferring the Danish West Indies to the United States (1917) contained a clause recognizing Denmark's right to extend her economic and political sphere over the whole of Greenland. Soon after the outbreak of the World War Russia notified a formal claim to the Arctic islands lying N. of Asia. In Aug. 1914 Capt. Isliamov hoisted the Russian flag on Franz Josef Land in anticipation of any claim that Austria might sustain by right of discovery. The Supreme Council in 1919 conferred the sovereignty of Spitsbergen and Bear I. on Norway. All the islands of the American Arctic Archipelago are claimed by Canada.

Bibliography.—F. Nansen, *In Northern Mists* (1911), throws new light on the early history of Arctic exploration. A bibliography of much use but limited scope is by J. M. Hulth, "Swedish Arctic and Antarctic Explorations," 1758–1910, *K. Svenska Vet. Akad. Årsbok för 1910. Les Expéditions polaires depuis 1800: Liste des États-Major*, by J. Denucé (1911) covers both Arctic and Antarctic. A useful general "Map of the Arctic Regions" with a list of authorities, appeared in *Bull. Amer. Geog. Soc.* 45 (1913). The Danish work in Greenland is recorded mainly in *Meddelelser om Grönland;* in vol. xli. (1913) G. Amdrup, "Report on the Danmark Expedition, 1906–1908"; in vol. lii. (1915) E. Mikkelsen, "Report on the Alabama Expedition, 1909–1912"; in vol. li. (1915), K. Rasmussen, "Report on the First Thule Expedition, 1912"; in vol. liii. (1917), H. P. Steensby, "An Anthropogeographical Study of the Origin of the Greenland Eskimo." For other Danish work see K. Rasmussen and others, *Grönland langs polhavet, udforskningen af Grönland fra Melvillebugten til Kap Morris Jesup: Skildring af den II. Thule Expedition, 1916–18* (1919), also E. Mikkelsen, *Lost in the Arctic* (1913). Official reports of the Stefansson expedition in *Report of the Dept. of Naval Service*, Ottawa, 1915, 1916, 1917 and 1918; also *Report of the Canadian Arctic Expedition 1913–18* (10 vols. Ottawa, in course of publication); "The Activities of the Canadian Arctic Expedition from 1916–1918," V. Stefansson, *Geog. Rev.* Oct. 1918; V. Stefansson, *My Life with the Eskimo* (1913), and R. A. Bartlett and R. T. Hale, *The Last Voyage of the Karluk* (1916). For Vilkitski's work see translation from Russian in *Geog. Journal* vol. liv. pp. 367–375 (1919) and *Petermanns Mitteilungen*, vol. lx., 1, 1914. pp. 197–8. Accounts of the Crocker Land expedition are to be found in the *Geog. Rev.* from 1913 onwards and in *U.S. Naval Inst. Proc.* vol. xliii., 1917, and vol. xliv., 1918. F. Nansen, "Spitsbergen

Waters," *Vidensbabs. Selskabets Skrifter No. 2* (Kristiania 1915), contains oceanographical investigations in the Barents and Greenland seas. (R. N. R. B.)

ARDILAUN, ARTHUR EDWARD GUINNESS, 1ST BARON (1840–1915), Irish philanthropist and politician, was born at St. Anne's, Clontarf, Nov. 1 1840, the eldest son of Sir Benjamin Lee Guinness, 1st bart., head of the famous brewing firm of Guinness. He was educated at Eton and Trinity College, Dublin, and in 1868 succeeded to the baronetcy on the death of his father. He then became head of the firm of Guinness, but shortly afterwards retired. He entered Parliament in 1874 as Conservative member for the city of Dublin, holding the seat till 1880, when he was raised to the peerage. In 1891 he bought St. Stephen's Green, Dublin, and converted it into a charming park, which he presented to the city. He also bought up various blocks of slum dwellings and converted them into model tenements, with the object of improving the conditions of the poorer classes of Dublin. Lord Ardilaun, who married in 1871 Lady Olivia White, daughter of the 3rd Earl of Bantry, died at Clontarf Jan. 20 1915.

ARENSKY, ANTON STEPHANOVITCH (1861–1906), Russian musical composer, was born in Novgorod July 31 1861, and after studying with various teachers finally became a pupil of Rimsky-Korsakov at the conservatoire of St. Petersburg. In 1882 he became a professor at the Moscow conservatoire, and from 1894 to 1901 was director of music in the imperial chapel at St. Petersburg. His works consist largely of chamber music, including the well-known trio, besides several operas, the chief of which are *The Dream on the Volga* (1890); *Raphael* (1894); and *Nal and Damayanti* (1899). He died at Terioki, Finland, Feb. 25 1906.

ARGENTINA (*see* 2.460).—The pop. of the republic in 1920, according to the calculation made by the Census Bureau, was 8,533,431. The latest census which had then been taken, that of 1914, gave the pop. at that time as 7,885,237, indicating an increase during 1914–9 of 648,194, or 8·2 %. The pop. of the political divisions was as follows:—

	1920 Calculation by Census Bureau, Dec. 31 1920	1914 National Census
Federal Capital	1,676,041	1,575,814
Isla Martin Garcia	—	783
Provinces:		
Buenos Aires	2,336,507	2,066,165
Santa Fé	1,007,512	899,640
Entre Rios	475,236	425,373
Corrientes	371,815	347,055
Córdoba	805,940	735,472
San Luis	129,655	116,266
Santiago del Estero	298,110	261,678
Tucumán	350,681	332,933
Mendoza	311,740	277,535
San Juán	131,179	119,252
La Rioja	84,643	79,754
Catamarca	108,544	—
Salta	146,903	140,927
Jujuy	76,506	76,631
Territories:		
Chaco	52,258	46,274
Chubut	28,813	23,065
Formosa	21,880	19,281
La Pampa	124,294	101,338
Los Andes	2,671	2,487
Misiones	62,159	53,563
Nuequen	33,574	28,866
Rio Negro	47,693	42,242
Santa Cruz	11,603	9,948
Tierra del Fuego	2,559	2,504
Total	8,698,516	

The pop. of the chief cities, according to the latest statistics available, was as follows:—

Buenos Aires	1,668,072
Rosario	222,592
Córdoba	156,000
La Plata	105,000
Tucumán	91,216
Santa Fé	59,574
Mendoza	58,790
Bahia Blanca	44,143
Paraná	36,089
Corrientes	28,681
Salta	28,436

The nationalities most largely represented in the pop., according to the census of 1914, were:—

Argentines	5,527,285
Italians	929,863
Spaniards	829,701
Russians	93,634
Uruguayans	86,428
French	79,491
Turks (mostly Syrians)	64,639
British	27,692
Germans	26,995
Swiss	14,345
Portuguese	14,143

There were also about 15,000 Indians and 500 negroes then in Argentina.

Agricultural and Mineral Production.—The total area under cultivation in Argentina was 20,367,082 hectares (50,330,096 ac.) in the season 1910–11 and 24,784,892 hectares (61,218,683 ac.) in the season 1917–8, an increase of 10,889,587 ac., or 21·6 %. The area under the principal crops for the season 1917–8 was:—

	Hectares.
Wheat	7,234,000
Lucerne (alfalfa)	8,052,805
Maize (Indian corn)	3,527,000
Oats	1,295,000
Linseed	1,308,600
Barley	244,355
Vines	116,145
Peanuts	26,725
Cotton	11,775
Tobacco	10,725
Sugar-cane	93,310
Potatoes	134,645

The development of cotton-growing in Argentina is especially noticeable, the area under cultivation having increased from 879 hectares in 1895 to 3,300 in 1914 and 11,775 for the 1917–8 crop. The Government has devoted much time and money to its development and has sent young men to the United States to study cotton-growing. Exports of wheat totalled 2,996,408 tons in 1918, maize 664,683 tons, oats 542,097 tons and linseed 391,382 tons, lack of shipping preventing greater exports. These figures may be compared with those for 1908 when 3,636,294 tons of wheat (more than ever before), 1,055,650 tons of linseed (also more than ever before), 1,711,804 tons of maize and 440,041 tons of oats were exported.

Argentina was in 1920 the world's largest exporter of linseed and maize (Indian corn), and third in exports of wheat, being only exceeded in the latter commodity by the United States and Canada. Her crop nearly equalled Canada's for several years preceding 1921. It has been estimated that approximately 80% of the soil of the republic is capable of yielding some form of economic return, but that only about a quarter of such land was in 1920 under any form of cultivation, while practically no part of Argentina is under intensive husbandry. Agricultural education in its various phases greatly progressed in Argentina during the 10 years 1910–20 under the guidance of Dr. José Léon Suarez in respect of national education and under such local leaders as Dr. Juan B. Teran at Tucumán in the provinces. The inauguration of the university of Tucumán in May 1914 and the development of its instruction in the production of sugar, cotton and other products suited to northern Argentina has been of great benefit to a large section of the country.

In 1917 there were 860 creameries, 470 cheese factories, 27 butter factories and 689 "mixed" establishments, the export of cheese having increased greatly during the World War. There were 408 flour mills, capitalized at $36,933,659. Most of these were in the provinces of Buenos Aires, Santa Fé and Córdoba. Exports of wheat flour increased from 118,486 tons in 1911 to 176,445 tons in 1918. Argentina produces approximately 350,000 bales annually of wool and there are 14 wool-washing establishments in the country. There were 29 breweries in 1914, and 4,663 establishments for the production of wine in 1917. The wine industry centres in the provinces of Mendoza and San Juan.

The output of all the packing and curing houses in 1914 was $114,960,886. The petroleum output at Comodoro Rivadavia increased from 14,784 kg. in 1907 to 198,672,698 kg. in 1918.

Foreign Commerce.—The imports and exports for the years 1914–8 are shown in the following table:

	Imports.	Exports.
1914	£64,505,992	£ 80,626,303
1915	61,097,601	116,435,855
1916	73,226,114	114,599,904
1917	76,064,235	110,034,009
1918	99,325,943	159,021,120

The amount of trade with each of the five countries with which Argentina does her chief foreign business is shown for the year 1918 in the following table, the amounts being in pounds sterling:—

	Imports from—	Exports to—
United Kingdom	£24,819,739	£60,690,730
United States	33,632,331	32,768,180
France	5,149,700	22,430,986
Italy	3,969,995	7,992,252
Brazil	9,796,341	6,616,380

Although Germany ranked second after Great Britain in imports into Argentina in 1913, her trade sank to practically nothing during the World War; it has since shown signs of increasing. The chief articles imported by Argentina are cottons and woollens, iron and steel, hardware, machinery, railway equipment of all kinds, lumber and coal. The chief exports are agricultural: wheat, maize, linseed, oats, wool, and meats, chiefly beef and mutton. The customs receipts were £19,795,749 in 1913; £12,135,528 in 1914; £9,901,664 in 1915; £10,726,026 in 1916 and £9,800,114 in 1917. The commercial depression which began about the middle of 1920 proved very injurious to Argentine foreign trade, curtailing both imports and exports.

Finances.—The expenditure and revenue of Argentina for the years 1915–20 are shown in the following table, the amounts being in pounds sterling:—

	Revenue.	Expenditure.
1915	£34,602,288	£34,572,625
1916	34,602,288	34,572,625
1917	32,962,569	33,973,357
1918	32,860,306	34,409,000
1919	34,969,953	35,671,023
1920	39,255,764	39,245,706

The 1919 and 1920 figures are budget estimates.

Railways.—Argentina in 1920 was tenth among the nations of the world and third among American nations in respect of her railway mileage. In 1910 the total was 17,403 m.; in 1915, 21,551 m.; and in 1920, 21,915 m.

Army and Navy.—The estimated army budget for 1920 was £3,000,000 and the naval budget £2,004,611. The total peace establishment of the army was in 1920 approximately 1,751 officers and 18,000 men. In addition there was a trained reserve of 300,000 men, 150,000 of whom were of the first line, and 150,000 of the special reserve. A territorial reserve was in process of formation. The navy consisted of two Dreadnoughts, two pre-Dreadnoughts, four armoured cruisers, and one old light cruiser. There were also seven destroyers, being with the Dreadnoughts the only modern units in the Argentine navy. The Dreadnoughts "Moreno" and "Rivadavia" were built in the United States and launched in 1917. Their displacement is 27,940 tons each and their nominal speed 22·5 knots. The personnel of the navy included 316 executive and 97 engineer officers, 23 electrical engineers, and from 5,000 to 6,000 men. There was also a coast artillery corps of 450 men.

The addition of the "Rivadavia" and the "Moreno" to the Argentine navy was by far the most important event in its development since 1910. Since 1914 the German influences in the Argentine army have somewhat abated with the return of the German military instructors to Europe. Both the army and the navy seemed in 1920 to turn more toward British, French and U.S. methods; no less than 23 naval officers were in that year undergoing instruction in the United States.

History.—The administration of President José Figueroa Alcorta came to an end Oct. 12 1910, when the inauguration of Roque Saenz Peña took place. Although early in 1910 an attempt had been made to conduct a campaign on behalf of Guillermo Udaondo, former governor of the province of Buenos Aires, as an opposition candidate to Saenz Peña, this movement did not develop much strength and Saenz Peña was elected without opposition. He was the son of Luis Saenz Peña, who had been President from 1892 to 1895, but was of a more cosmopolitan type, having spent much time in the Argentine diplomatic service, in both Europe and America. Victorino de la Plaza, who had been Minister of Foreign Affairs in the administration of Figueroa Alcorta, now became Vice-President. His long residence in England as Argentina's financial representative had placed him in close touch with sources of foreign investment which mean much to Argentina, and had given him a sympathetic point of view as regards foreign interests and affairs. Saenz Peña's Cabinet was a strong one. Dr. Indalecio Gómez, who had been Argentine minister to Germany, was Minister of the Interior and continued in this office throughout Saenz Peña's administration, while the Ministry of Foreign Affairs was filled by Dr. Ernesto Bosch, who had also been in the diplomatic service. Saenz Peña had no less than four Secretaries of the Treasury, beginning with Dr. José Maria Rosa, who had put Argentina's finances on a gold basis when Minister of the Treasury in Roca's administration in 1899 and possessed much knowledge of financial affairs. His successors were E. S. Pérez, Norberto Pinero and Lorenzo Anadón. Dr. Juan M. Garro and Dr. Carlos Ibarguren were Saenz Peña's Ministers of Public Instruction and Worship, Gen. Gregorio Vélez and Rear-Adml. Saenz Valiente holding the War and Navy portfolios throughout the Administration. Esquiel Ramos Mejia, who had been in the Cabinet in the previous Administration, and Carlos Meyer were the Ministers of Public Works, and Adolfo Mujica Minister of Agriculture.

President Roque Saenz Peña died Aug. 9 1914, Vice-President de la Plaza succeeding him. An entirely new Cabinet, except for the Navy portfolio, which continued to be held by Adml. Saenz Valiente, came into office Aug. 9 1914. Manuel Ortiz became Minister of the Interior; José Luis Murature, who had long been an editor of *La Nacion*, one of the most prominent Buenos Aires newspapers, Minister of Foreign Affairs and Worship; Manuel Moyana Minister of Public Works; Horacio Calderón Minister of Agriculture; and Gen. Angel P. Allaria Minister of War. The Treasury portfolio was held successively by Dr. Alejandro Carbo and by Dr. E. E. Oliver, and that of Justice and Public Instruction by T. R. Cullen and M. E. Lamas. The period of de la Plaza's presidency almost exactly coincided with the first two years of the World War. When it broke out England stood first in Argentine foreign trade, with Germany a close second. The English also led in the amount of foreign capital invested in Argentina, although French and German investments were also considerable. Through his term of office President de la Plaza maintained an attitude of strict neutrality on behalf of his country, though his personal preference and certain of his official acts showed an inclination toward the Allies.

In 1916, when de la Plaza's successor was to be chosen, divisions in the old Government party, which had been so long in power under various names, made it powerless to prevent the nomination and election of the candidate of the Radical party, Hipólito Irigoyen, who had never before held public office. For the first time in Argentine history the Radical party was in control of the Government and for the aristocrats (from whose ranks almost all the higher officials had been chosen) it substituted as members of the Cabinet either politicians of their own party or practical business men, such as Domingo Salaverry, the able Minister of the Treasury. Although the Ministry of Foreign Affairs and Worship was nominally filled, first by Dr. Carlos A. Becú, who resigned Feb. 3 1917, and then by Honorio Pueyrredón, who had previously been Minister of Agriculture, the able young Under-Secretary, Diego Luis Molinari, who had travelled in the United States and Europe, practically directed the actual management of Argentina's foreign relations during the first five years of Irigoyen's administration. Pueyrredón was not formally made Minister of Foreign Affairs until Sept. 13 1918. The

Interior Department was directed by Dr. Ramón Gómez throughout Irigoyen's term, the Ministry of Justice and Public Instruction by José S. Salinas, and that of Public Works by Pablo Torello. For the first time in the history of Argentina the Ministry of War was filled by civilians, Dr. Elpidio Gonzáles (until 1918) and his successor Dr. Julio Moreno. An engineer of some distinction, Federico Alvárez de Toledo, was Minister of Marine until his resignation in 1919, when Julio Moreno was entrusted with the Navy portfolio also. After Pueyrredón left the Ministry of Agriculture in 1917 Alfredo Demarchí, an engineer, assumed charge of that Department. The Vice-President, Dr. Pelagio B. Luna, from the province of La Rioja, who was supposed to represent the Radical influence in the interior of the country, died June 25 1919. Benito Villanueva then became president of the Senate and therefore next in succession to the presidency, although he did not belong to the President's political party. The elections in 1919 strengthened the hold of the President and the Radical party over both Houses of Congress and gave the Radicals reason to hope that they would continue in power and win the 1922 presidential elections, in spite of differences of opinion among some of the leaders in the party and the inevitable disputes as to who should be the candidate.

With the entry of the United States into the World War in April 1917, the attitude of Argentina, like that of many other Latin-American countries, became divided. One strong party desired a rupture of relations with Germany, while another believed that Argentina's future position of independence should be safeguarded by a strict neutrality. The general mass of the population was strongly in sympathy with the Allies, with the natural exception of the 26,000 German subjects and the 40,000 others of German origin. Their influence was particularly strong in Argentina because of the excellent German organization there and because of the feebleness of the Allied propaganda until the war was nearly over. For some time after the outbreak of the war in 1914 it had been feared that all the skilled workers and other immigrants of the better class would return to fight for their native lands; and during 1917, 1918 and 1919 44,285 more persons did leave the country as steerage passengers than entered it; at the same time the cost of living rapidly advanced, and there was a corresponding spread of social unrest, partly due to the popular feeling that the President had espoused the cause of labour and so was disposed to listen sympathetically to the claims of the various labour organizations. This attitude brought him into conflict with the English-owned railways, which comprised 74% of the railways of Argentina, and did not discourage the serious strikes of 1917, which were supposed to have been instigated by German agents. The most disastrous of these was the general railway strike which paralyzed traffic throughout the country from Sept. 23 to Oct. 17 1917. Moreover, labour agitations and strikes of all kinds continued to develop in all parts of the country. They distracted public attention from international to local issues.

On Sunday, Sept. 8 1917, the Buenos Aires newspapers published certain cablegrams which had been sent in May and June 1917 by the German Minister at Buenos Aires, Count Luxburg, to the German Foreign Office, in one of which he said: "As regards Argentina's ships, I advise that they be compelled to go back or that they be sunk without leaving any trace (*spurlos versenkt*) or not allowed to pass." Four Argentine merchant vessels, the "Oriana," "Monte Protegido," "Toro" and "Curumalan," were sunk by the Germans. The publication of these cablegrams caused great excitement in Buenos Aires and four days later, on Sept. 12, Honorio Pueyrredón, the acting Minister of Foreign Affairs, notified Luxburg that he was *persona non grata* to the Argentine Government. Pueyrredón had been personally offended by Luxburg's allusion to him as a "notorious ass" in the published telegrams. On the evening of the same day a large mob destroyed the largest German club in Buenos Aires, attacked the premises of the three pro-German newspapers and seriously damaged a number of German business establishments. Popular indignation was increased by the operation of a high-powered German radiograph station near Buenos Aires designed to communicate with Nauen, near Berlin. Pamphlets and leaflets were circulated telling of German designs on South America. Intense excitement reigned in the Argentine capital, and on Sept. 19 the Argentine Senate voted by 23 to 1 in favour of breaking diplomatic relations with Germany. On Sept. 24 the Chamber of Deputies voted a like resolution by 53 to 18. A large number of senators and other prominent persons took part in a large and significant pro-Ally parade on Sept. 20. In spite of all this anti-German manifestation, however, the President maintained an attitude of strict neutrality and the German legation continued to function under Count Donhoff as chargé d'affaires, while German intrigues in Argentina continued unabated, spreading thence throughout Latin America. But a large number of volunteers joined the Allied armies, and the Argentine communities gave freely to Allied Red Cross.

Education.—The following table gives the amounts appropriated for Education in 1910, 1915 and 1920 in U.S. dollars.

	1910	1915	1920
Federal Government	$15,480,305.69	$21,043,708.46	$28,280,897.60
Provinces:			
Buenos Aires	3,632,227.56	4,464,213.73	6,262,464.92
Santa Fé	700,801.00	1,182,212.82	1,173,831.87
Entre Rios	510,465.82	762,557.19	1,074,034.01
Corrientes	250,764.76	435,858.42	467,749.36
Córdoba	810,207.89	970,644.06	1,509,741.04
San Luis	101,851.41	101,831.41	88,430.76
Mendoza	325,362.18	325,463.18	450,550.00
San Juan	177,035.17	144,670.41	300,069.47

Salta	236,389.30	251,056.37	213,838.40
Jujuy	119,072.94	165,000.00	167,882.79
	$23,300,133.66	$31,985,696.15	$41,303,511.12

(C. L. C.)

ARGONNE, BATTLES IN THE, 1914–6. (For the battle of Sept.-Nov. 1918 between American and German forces, see MEUSE-ARGONNE, BATTLE OF.)—On Sept. 14 1914 at early dawn the advanced guards of the French II. Army Corps left Ste. Menehould with orders to reach Grandpré the same day. The II. Corps was *en flèche*, about half a day's march ahead of the IV. Army Corps, which was on its left, and of the left corps of the III. Army on its right. At about 12 o'clock one of the advanced guards of the II. Corps carried, by a forced attack, the village of St. Thomas, a kind of natural fortress dominating the valley of the Biesme. A German staff officer was killed, on whom was found an order of the IV. German Army commanding them to hold the "fortified positions marked by La Justice (2 km. south of Cernay), hills 147 and 148, height 140 (between Servon and the Bois de Cernay), the Mare aux Bœufs, Bagatelle . . ." In the evening of the 14th the French Colonial Corps was stopped by the resistance of the enemy at Ville-sur-Tourbe; the II. Corps carried Servon, but, isolated by the delay of the III. Army and the check to the Colonial Corps, it could not emerge therefrom. It may be said that on the evening of Sept. 14 mobile warfare ceased in Argonne and trench warfare began.

The German staff had left the valley of the Biesme to take up its positions farther back; this decision seems to have been speedily regretted, for on the morning of the 15th great efforts were made by the Germans to regain the heights dominating the Biesme. The French forces tried at first to continue their northward march, but they soon felt the uselessness of their efforts. Then position warfare was accepted, but so regretfully that immobility was found difficult to observe; time was wasted, and, in war, time is blood. Nevertheless, the return towards the Biesme attempted by the Germans as early as Sept. 15 had not yet been completely successful by July 1918, at which moment the *débâcle* for Germany began. On Sept. 15 1914 the Germans retook Servon, but could not debouch from it. Their efforts to do so remained fruitless during the whole of the war.

Further westwards the II. Corps in vain attempted to reach Binarville. The Germans retook the south edge of that village and gained ground in the woods of La Grurie; but they came up against the most tenacious resistance and were never able to seize Vienne-le-Château, of which they did not leave a stone

standing. More to the east obstinate fighting took place all through the winter of 1914 and the spring of 1915 at Bagatelle, a small ruined hunting-box. Bagatelle fell into the hands of the Germans, but although the latter penetrated into the woods as far as La Harazée, they were unable to cross the Biesme there. The right of the IV. Army was at a spot called St. Hubert, near the Meurissons stream which ends at Le Four de Paris. Le Four de Paris was under the authority of the III. Army, commanded by Gen. Sarrail. The V. Army Corps, left of the III. Army, had not been so rapid in its pursuit as the II. Corps; the liaison of the two armies could, therefore, not take place, as had been planned and was desirable, at the crossing-point of La Viergette on the Haute Chevauchée; the crossing-point was taken by the Germans. On Sept. 23 and 24 the V. Corps, which had succeeded in reaching Montblainville, gave way, lost Varennes and allowed the enemy to approach Meurissons and Le Four de Paris.

On Sept. 29 the XVI. German Corps attacked La Chalade, Le Four de Paris and La Harazée simultaneously, and reached the vicinity of the Biesme. It must be noted that, at that same time, Gen. von Strantz's army forced the Hauts de Meuse, entered St. Mihiel, seized Fort Camp des Romains, crossed the Meuse and endeavoured to advance westwards, beyond Chauvoncourt. This meant the envelopment of Verdun, by St. Mihiel and by the Biesme, and was the most critical period of the struggle in Argonne. But on Sept. 30 the German 98th was taken by surprise near La Chalade, two of its battalions being completely destroyed, or nearly so. The Germans were driven back to and beyond St. Hubert. Furious fighting went on at Bois de Bolante, La Fille Morte, and Courtes-Chanvres. From Oct. 6 the front was practically fixed in these parts.

On Nov. 20 1914 the 10th Div. of the French V. Corps, which was under Gen. Gouraud, became attached to the II. Corps. General Gérard, commanding the II. Corps, then became the real defender of Argonne, while the German facing him was Gen. von Mudra. On Jan. 5 1915 Gen. Gouraud made a successful attack at Courtes-Chanvres.

The Germans had been greatly assisted, at the outset, by a special trench-warfare *matériel* from Metz. On the French side the *matériel* and special mine-warfare units had to be improvised. During the winter of 1914–5 there were no projectiles even for the guns, and those manufactured in haste made the British 75-mm. guns explode.

Shortly after the II. Corps had settled in Argonne the French general-in-chief shifted the limit of the armies. The Aisne now marked the right of the IV. Army, commanded by Gen. de Langle de Cary, and the left of the III. Army, under Gen. Sarrail, whose headquarters were at Ste. Menehould. Ste. Menehould on one side and Varennes on the other were the fountain-head of all orders. Gen. Sarrail in the south, the German Crown Prince in the north, organized the combats that were more often sacrifices. The Aisne in the west, the Oise and the Verdun region in the east, were the limits of that bloody battlefield where the fighting was conducted in the woods, in trenches which were little more than streams, owing to the extreme dampness of the soil. The men were dying from cold and frozen feet; they were so worn out that the slightest wound became mortal.

It would be tedious to enumerate the units, both large and small, that passed through Argonne, won fame and wore themselves out. Nevertheless, mention must be made of the Garibaldi brothers and their legionaries, who, with heroic courage, showed the Germans in a fierce assault that Italian steel is as good as its men.

General Gérard was replaced, on Jan. 15 1915, by Gen. Humbert. The latter was appointed commander of the III. Army, after Gen. Sarrail's reverse, in the month of July 1915.

By the month of Feb. 1916 Verdun had become the centre of the gigantic struggle; Argonne was never quite calm, but the fighting there henceforth took the second place; large numbers of men were no longer sacrificed as at the outset. The armaments balanced little by little and, in Argonne especially, when the Germans had no *matériel* superiority, they no longer dominated in any way.

By a close examination of facts, one may convince oneself that the value of the German armies was due much more to the German war preparations, German material organization for war, than to the value of the soldiers and those in command. Had the Germans been obliged to improvise the defence of Argonne as the French were, they would have been defeated at a very early stage. (V. L. E. C.)

ARIZONA (*see* 2.544). In 1920 the pop. was 334,162 as against 204,354 in 1910, an increase of 129,808, or 63·5%. This was the largest percentage of increase shown by any state. The pop. of the chief cities was as follows: Tucson, 20,292 (13,193 in 1910), Douglas, 9,916 (6,437 in 1910), Bisbee, 9,205 (9,019 in 1910). The average number of inhabitants to the square mile in 1920 was 2·9 as compared with 1·8 in 1910. The rural pop. constituted 64·8% of the whole in 1920 as against 69% in 1910.

Agriculture.—During the decade ending in 1920 agriculture underwent remarkable changes. There was a considerable increase in the number of acres irrigated, from 320,051 ac. in 1909 to 467,349 ac. in 1919, a gain of 46%. Almost a third of this gain was in Yuma county as a result of the Laguna Dam; the greater portion of the remainder was the result of pumping in other counties. The greatest change was the transition from dairy farming to cotton growing. In 1916 the dairy business reached its height, when the dairy cattle in the Salt River Valley were estimated at 60,000. The introduction of long staple cotton reduced this number to about 8,000 at the end of 1920. The development of the cotton industry was notable; in 1914 there were 13,300 ac. under cultivation, and in 1920, according to estimate, 180,000 ac. This increase, coupled with the great rise in the price of cotton, caused cotton land to rise from $300 and $400 to $700 and in some instances to $1,000 an acre. The great fall in the price of cotton was expected, if it proved permanent, to result in a return to dairy farming and lower land values.

Minerals.—In 1910 Arizona's production of 297,250,538 lb. of copper placed her first among the producing states. This increased to 559,235,000 lb. in 1920. The tendency during 1910–20 was toward the development of grade deposits, the Miami Copper Co., the Inspiration Copper Co., the New Cornelia Copper Co., and the Ray Consolidated Copper Co. being conspicuous for this type of work. The older companies such as the Copper Queen, the United Verde, and the Calumet and Arizona copper companies still had high-grade deposits in 1920; but the Copper Queen turned in the direction of low-grade ores, having completed the stripping of Sacramento Hill near Bisbee. The plant for handling this huge low-grade deposit was to be completed in 1921. The yield of gold and silver was not unimportant. Gold production increased from 152,350 oz. in 1910 to 380,034 oz. in 1920; and silver from 2,566,528 oz. in 1910 to 6,098,251 oz. in 1920. Gold production increased mainly because of the output of the Tom Reed and the United Eastern mining companies, the latter producing one-fourth of the total for the state in 1920. Considerable amounts of gold and silver were also obtained in treating copper ore.

Manufactures.—The following table shows the growth of manufactures:

	1919	1909
Number of establishments	480	311
Proprietors and firm members	416	261
Salaried employees	1,403	500
Wage earners, average number	8,528	6,441
Capital	$101,486,070	$32,872,935
Salaries	3,111,838	798,141
Wages	12,014,769	5,505,183
Cost of materials	92,645,437	33,600,240
Value of products	120,769,112	50,256,694
Value added by manufacture	28,123,675	16,656,454

The principal industries in 1920 were the smelting and refining of copper, cars and general shop construction and repairs by steam railway companies, flour-mill and gristmill products, lumber and timber products.

Education.—The progress in public education in the decade 1910–20 was greater than the increase in population. In 1916 a high school of the state was for the first time admitted to the North Central Association of Colleges and Secondary Schools. In 1920 there were in the association 14 of the 29 high schools of the state. The growth of the normal schools at Tempe and Flagstaff kept pace in enrolment and equipment with the growth of the public schools. In 1910 there was organized a state school for the deaf, affiliated with the university of Arizona and under its direction. The university of Arizona increased from an enrolment of 84 regular college students in 1910–11 to one of 892 for the first semester of 1920–1. This institution in 1921 was composed of three colleges and two schools on the campus at Tucson: college of Letters, Arts and Sciences; college of Mines and Engineering; college of Agriculture; school of Law and school of Education. The Agricultural Experiment Station, the Arizona bureau of mines, the state pure food laboratory and the state museum were also on the campus. In 1916 the university of Arizona was

admitted to the North Central Association, and in 1919 it became a member of the Association of American Colleges.

History.—During the years 1910–20 Arizona provided two issues of national interest. The first of these was her admission to the Union. As provided by the Enabling Act signed by President Taft June 30 1910, a constitutional convention met at Phoenix from Oct. 10 to Dec. 9 1910 to frame a constitution. The constitution then adopted provided that one-fourth of the electors of a judicial district might, by petition, demand the recall of a judge. If he did not then resign a special election could be held to determine whether he should be recalled. In Aug. 1911 the National House of Representatives by a vote of 214 to 57 passed a joint resolution providing for the admission of Arizona on condition that the constitutional provision for recall be submitted to a vote of the people. President Taft had already informed Congress that he would not sign the bill, and in a message to Congress took the position that he must veto the measure or assume responsibility for the recall of judges. Later in August he approved a resolution granting statehood on condition that the voters in the general fall election strike out the provision for recall. This they did; and on Feb. 14 1912 President Taft signed the proclamation admitting Arizona. After the state was admitted the people amended the constitution, inserting the original clause providing for the recall of judges. The presidential vote in 1912 was 10,324 for Wilson, 6,949 for Roosevelt, and 3,021 for Taft; in 1916, 33,170 for Wilson and 20,524 for Hughes; in 1920, 37,016 for Harding and 29,546 for Cox. Arizona's Alien Labour law provided the other issue of national interest. The voters of the State, 1914, by a majority of 10,684, enacted a law providing that when any corporation, company, partnership, or individual employed more than 5 workers, 80% of these should be qualified electors or native born citizens. The ambassadors of Great Britain and Italy claimed that the law violated existing treaties. The U.S. District Court declared the law unconstitutional as conflicting with the Fourteenth Amendment. On appeal the U.S. Supreme Court upheld this decision, Nov. 1 1915. Justice Hughes in the final decision said that it had already been established that aliens were entitled to equal protection of our laws. The election of Nov. 1916 resulted in a gubernatorial contest that aroused high party feeling. Governor Hunt, supported by a Democratic assembly, had been elected for two terms. He ran for a third time in 1916. On the face of the returns Campbell, the Republican candidate, was elected; but both candidates came to Phoenix in Jan. to be inaugurated, and Hunt refused to leave the executive office. Later he was compelled to surrender the office to Campbell, but assumed it again in Dec. 1917 after the state Supreme Court had declared him the legally elected governor. At the next election in 1918 Campbell was chosen governor, and he was reëlected in 1920. The bitter political struggle was largely the outgrowth of an industrial situation that culminated in a number of strikes throughout the state. That at Clifton and Morenci beginning in Sept. 1915 roused the widest interest. This strike, conducted for the most part by Mexican labour, was organized and at first directed by agents of the Western Federation of Miners. The unique characteristic of the struggle was the sympathy for the strikers shown by the chief executive of the state, Governor Hunt having ordered in the early days of the strike that no strike-breaker should be admitted into the district. Another singular characteristic was the absence of the usual violence. This was attributed to the action of the sheriff who deputized strikers themselves to protect the property of the company. There was no loss of life, and although a large concentration plant at Clifton was destroyed by fire, this was not proved to be the work of strikers. After repeated attempts at conference, no settlement was reached till the Western Federation of Miners withdrew, leaving the Arizona State Federation of Labor in charge. An increase of wages was granted; but the managers asserted that this was the natural result of the increased price of copper, and that they had in no way yielded to the strikers. The industrial strife reached even a more crucial stage in the summer of 1917 when the Bisbee deportation incident occurred. The employees in several of the mines had struck for higher wages and better working conditions, claiming that they had been the losers in the general rise in prices, and that they had not shared in the profits due to the increased value of copper. There was a general fear that violence would result from the activities of the Industrial Workers of the World. Sheriff Wheeler, supported by the conservative citizens of Bisbee, took the position that the members of the I.W.W. and their sympathizers were vagrants, traitors, and disturbers of the peace of the county. In July 1917 the sheriff and his many deputies rounded up over 1,100 of the alleged offenders and deported them to Columbus, N.M. President Wilson at once warned Governor Campbell of the danger of such a precedent; and two months later, at the solicitation of Samuel Gompers, he appointed a committee, of which Secretary Wilson of the Federal Department of Labor was chairman, to investigate and adjust the industrial disputes. This committee found that there was no machinery whereby the grievances could have been adjusted, since the managers refused to recognize certain labour organizations. The committee further recommended that Congress make future deportations a Federal offence. A number of indictments against Wheeler and his deputies were secured; and one case, the State of Arizona *v.* H. E. Wootton, came to trial. The defendant was freed on the plea of the "law of necessity"; the other cases were not pressed. The last territorial governor was Richard E. Sloan, 1909–11. State governors were George W. P. Hunt (Dem.), 1911–9; Thomas E. Campbell (Rep.), 1919– .

ARKANSAS (*see* 2.551). In 1920 the pop. was 1,752,204 as against 1,574,449 in 1910, an increase of 177,755, or 11·3%. Of the total pop. in 1920, 1,265,782, or 72·2%, were native whites, 472,220, or 27%, negroes, and only 13,975, or 0·8%, foreign-born whites. There were 121,837 illiterates, of whom 79,245 were negroes, 41,411 native whites, and 1,145 foreign-born whites. The pop. was decidedly rural, only 290,497, or less than one-sixth, being classed as urban. The average number of inhabitants per square mile in 1920 was 33·4 as against 30 in 1910. Little Rock was the largest city, with a pop. of 65,142 (45,941 in 1910), of whom 17,477 were negroes. The pop. of the other leading cities was as follows: Fort Smith 28,870 (23,975 in 1910), Pine Bluff 19,280 (15,102 in 1910), and Hot Springs 11,695 (14,434 in 1910).

Agriculture.—Agriculture was still the leading industry in 1920 and, in spite of the ravages of the boll-weevil, cotton was the leading crop. In 1916 2,635,000 acres produced 1,134,000 bales, valued at $111,135,000, and 504,000 tons of seed. The crop of 1919 was considerably less, 869,550 bales, but was valued at $159,960,400; that of 1920, 1,177,095 bales. Arkansas cotton is of a high quality, the price paid for it being exceeded in America only by that of Florida, California, Arizona and Mississippi. In recent years there has been considerable agitation in favour of diversified farming, and this has caused an increase in the production of cereal crops and hay. The corn crop of 1919 (34,226,935 bus.) was valued at $61,608,482. The development of the rice industry has been very rapid. Introduced in 1904, the production was 2,400,000 bus. in 1910, 6,797,126 in 1919, and 7,780,000 in 1920. The state ranked high in the production of apples, both in quality and quantity. In the production of peaches it ranked next after California, Texas and Georgia and was said to contain the largest of all orchards. The crop was 3,340,823 bus. in 1919. The strawberry crop was valued at over a million dollars a year. The state ranked fourth in the acreage devoted to vineyards. In 1921 plants were erected for the making of grape-juice. In the last few years considerable attention has been given to the introduction of pure-bred live stock. The total value of the farm products in 1919 was estimated at $341,565,356 as compared with $175,057,000 in 1916.

Manufactures.—In 1909 there were 2,925 manufacturing establishments employing 44,982 workers and turning out products valued at $74,916,000; the value in 1919 was estimated at $100,000,000. Lumber was the leading industry, cotton-seed oil the second. Sixty different kinds of trees are cut for the market, hardwood and pine being the most common. The annual cut was about 5,000,000,000 board ft., of which 2,111,200,000 was lumber. The supply of standing

timber was estimated in 1920 at 78,700,000,000 feet. The chief centres of manufacturing were Little Rock, Fort Smith, Pine Bluff, North Little Rock, Helena and Hot Springs. A considerable impetus was given to manufactures, especially in glass, in Fort Smith by the discovery of gas.

Banks and Finance.—In 1920 there were 404 state and private bank and trust companies and 76 national banks with capital and reserves amounting to $29,549,357 and resources amounting to $273,915,676. The state banks had 389,383 depositors. There were no separate savings banks, but the savings deposits in the banks amounted to $12,450,710. The increase in the ratio of the banking resources of the state to those of the nation during the years 1909–19 was exceeded only by Oklahoma and Nevada. There were few bank failures for several years and depositors lost little, though there was no guarantee law. The state budget amounted to $6,546,470. The recognized debt amounted to about $2,000,000 provided for by special tax. Revenue was derived mainly from the general property tax, but a considerable sum was secured from licenses and poll taxes. In 1920 the assessed valuation, real and personal, was $612,426,000, which is only a small part of the real value. The appropriations for 1921–3 total $14,241,395, which was well within the estimated revenue. The largest item, apart from the state aid to public schools, was $2,400,000 for pensions to Confederate veterans.

Education.—The school population was in 1920 676,009, of whom 483,172 attended school. For support of the schools the state and districts expended $7,600,000 annually. The state university is supported by a special tax which in 1912 was one mill per $1 of assessed valuation. An amendment to the constitution, submitted by initiative, removing the limit on taxes for school purposes, was to be voted on in 1922.

Transportation.—In 1910 the state had 4,876 m. of steam railway; in 1920, 55,220 m. There were in 1920 eight electric street and inter-urban lines with 152 m. of track. In the same year 59,058 motor-cars, trucks and tractors were licensed. By the close of 1920 the road-building programme comprised 9,000 m. at an estimated cost of $108,000,000, about half of which was under construction or contract. Dissatisfaction, partly over the cost and partly over the fact that only real estate was assessed to pay for these roads, led to the abandonment of many of those projected. Some of the roads were to be asphalt or concrete, but the prevailing type was gravel. As the counties were forbidden to issue bonds the work was carried on by improvement districts with state and Federal aid. The total amount of state aid available 1917–21 was $1,400,000; Federal, $4,615,210. To secure this aid the work done by the districts had to meet the approval of the state highway department.

Minerals and Mining.—The bauxite industry continued to develop, growing from 115,837 long tons in 1900 to 532,000 in 1918. All the other states together produced only 32,000 tons. Platinum was discovered near Batesville in 1920. The output of coal rose from 13,195 tons in 1880 to 1,701,748 tons in 1910 and to 1,994,738 tons in 1913; after this there was a slight falling off. The production of natural gas was small (125,000 ft. from six wells) until 1915, when the first strong well was opened in Crawford county. The output of the wells near Fort Smith was in 1920 about 200,000,000 ft., only one-fifth of which was used. In 1921 a strong well was developed near El Dorado; also, oil was discovered in the same region early in 1921, and by Aug. the production has risen to over a million barrels a month. The state ranks first in the production of whet-stones, which are made from the famous "Arkansas" and "Ouachita" oilstones. The clay in Saline county is used for making pottery of a very artistic type.

History.—The state continued under control of the Democratic party without interruption from 1874 to 1921. Several attempts have been made to amend the conservative constitution, most of which have ended in failure, owing to the requirement of a majority of the total vote to adopt any amendment. An initiative and referendum amendment was adopted in 1910, but a part of it was declared unworkable by the Supreme Court. In 1916 a new initiative and referendum, submitted by petition, was voted down; in 1920 it received a large majority of the vote cast, but not a majority of the total vote. It was again submitted by petition and will be voted on in 1922. In 1912 an amendment submitted under the initiative limited the pay of legislators to a session of 60 days, with half pay for an extra session of 15 days. The previous session had been long and expensive. The Legislature of 1917 called a constitutional convention. When the convention met, the United States had just entered the World War and a strong effort was made to adjourn without doing anything. As a compromise the convention adjourned to July 1918. It then met and submitted a revised edition of the old constitution. This was rejected by the people. Important legislation during the period 1910–20 included abolition of the convict lease system (convicts may now be worked on the roads); provision for a state farm for convicts; reform schools; state-wide prohibition (1915); inheritance tax; minimum wage; restricting child-labour; compulsory education; and abolition of the "fellow servants" rule. In 1917 women were by statute given the right to vote in primary elections; in 1920, before the adoption of the national woman suffrage amendment, an amendment to the state constitution giving full rights of suffrage and the right to hold office was submitted to the voters, but failed to receive a majority of the total vote. A legislative Act of 1921 gave women the right to hold office. In 1921 Gov. McRae induced the Legislature to make a beginning of reform in the state administration by abolishing a number of offices and commissions. The governors of the state since 1909 have been: George W. Donaghey, 1909–13; Joseph T. Robinson, Jan. 8–March 1913; W. K. Oldham (acting), March 8–23; J. M. Futrell (acting), March 23–Aug. 6; G. W. Hayes, Aug. 6 1913–7; C. H. Brough, 1917–21; J. T. McRae, 1921– .

(D. Y. T.)

ARMENIA (*see* 2.564).—The years between 1914 and 1921 are, perhaps, the most important of any in the modern history of the Armenian people. The bloodless Turkish revolution of 1908, followed by the assembling of a representative Parliament, opened a period in which, for a time, racial animosities seemed to have disappeared from the greater part of the Ottoman Empire. Armenians hailed the change as the end of their troubles, and massacre and oppression became dim memories. They appeared content henceforward to be citizens of a reformed Turkey and anxious to bear their part in all the duties of citizenship. Some, indeed, went so far in their new-formed patriotism as to call themselves Osmanlis, seeking to make a national name of the term hitherto used only by Turkish Moslems—a term embodying in the past the very spirit of Turkish conquest and oppression. Nor was it merely the rank and file of the Armenian people who so readily accepted the prospect of a new Turkey. Leaders of Armenian revolutionary societies—organizations whose purpose was to achieve Armenian independence, the Hunchakists by constitutional means, the Dashnakists by violence—themselves believed that the Young Turk movement deserved well of the Armenian people, and that the revolution should receive Armenian support. We need not enquire too closely into the causes of this sudden confidence. The Young Turks possessed, as yet, little experience in organization; they were deficient in means: they therefore courted leading Armenians and the Armenian secret societies, from which sources, to some extent, experience and financial aid could be obtained. On their part Armenians held that any change which diminished the power of the Sultan 'Abdul Hamid and his creatures was so much to the good; and their leaders felt themselves competent to use the Young Turks for Armenian ends, and to go with them only so far as Armenian interests required. It is, indeed, a singular fact that the Young Turks and the Dashnakists continue to find some degree of usefulness in each other to the present time.

Cilician Massacres.—But disillusionment on the part of the Armenian people in general was not long delayed. The first free Ottoman Parliament met on Dec. 27 1908: in April 1909 massacre broke out at Adana, in the rich Cilician plain. After the first outbreak troops of the Young Turk army were hurriedly brought from Salonika, and the affair seemed to have been stamped out by the promptitude of the Government. But after a few days it flared up again, in consequence, it is stated, of Armenians having fired on the soldiery, who thereupon took an active part in the work of killing and burning. From Adana massacre spread to various towns of the vilayet of Adana, and into northern Syria, particularly at Antioch, Kirk Khan, and Mar'ash. Though thousands perished in the towns, a greater number were slaughtered in remote villages and on lonely roads; for it was the time when Armenians from the mountains were on their way to the annual harvesting on the fertile Cilician plain. It is believed that in all not less than 20,000 lost their lives in this unexpected and disastrous outbreak.

Origins of the Cilician Massacre of 1909.—The origins of these massacres remain obscure; that some form of official prompting lay behind them, however, cannot be doubted. Not

once but often it has been proved that Turkish authorities find no difficulty in preventing outbreaks of the kind if they choose; that, in fact, massacre is, at bottom, the result of official connivance more or less direct. The Cilician massacres have been charged to 'Abdul Hamid and his satellites, as an effort by him to discredit the government of the Young Turks. They have been charged to the Young Turks, as an effort by them to discredit 'Abdul Hamid, who had been deposed on April 9—just one week before the affair at Adana. Notwithstanding the vehement disavowal of complicity by the Government, and their ostentatious endeavours to compensate sufferers and provide for orphaned Armenians; notwithstanding the Turkish Commission of Inquiry, and the impartial hanging of Moslems and Armenians, time brings the guilt home more and more definitely to Young Turk leaders.

That the Armenians of Cilicia were blameless cannot be maintained. After the first fraternal demonstrations of the revolution they had adopted a manner toward their Moslem fellow citizens provocative and unwise beyond belief. They had indulged in Armenian national processions, displaying the flag of an independent Armenia; had publicly boasted that Cilicia itself was soon to become an independent Armenia; had insulted and beaten Moslems in the streets of Adana. To the fatal influence of these follies were added the economic facts that Armenian land-owners, already in possession of the richest areas of the Cilician plain, were rapidly increasing their holdings; and that the Armenian population prospered and multiplied while the Moslem population declined. The Moslems of Cilicia, indeed, were gloomily brooding over Armenian affronts to their patriotism, and economic Armenian encroachments on their position as the dominant and ruling race. These matters combined formed a mass of highly inflammable material.

Armenian Political Position.—As the Young Turk Government consolidated itself, and its control passed finally into the hands of the Subterranean Committee of Union and Progress, so the prospect of Armenians receiving equal treatment within the Empire disappeared. Armenian representation in Parliament was curtailed by means both direct and indirect. The total number of Armenians who might sit in the Chamber was arbitrarily fixed, irrespective of election results. The lists of voters were compiled under conditions that weighed against Armenians obtaining the vote in the proportion to which their numbers entitled them. In common with other Ottoman Christians the place of Armenians in the State became, in effect, that of undesirable aliens.

Turkish Wars of 1911–3.—The Italo-Turkish War of 1911–2 passed without changing the Armenian position. Nor did the first Balkan War, 1912–3, greatly affect the race except as to military service. During these wars it seemed, indeed, that massacre did not suit the policy of the Government, the desire being to stand well with the Powers. None therefore took place. In the Balkan War, however, military service fell heavily upon the Armenian subjects of the Empire for the first time. They were not permitted to serve forming Armenian units, but were distributed throughout the army; and the most laborious and dangerous duties are said to have been assigned them as a matter of policy. In these circumstances desertions were numerous, as might have been expected. But with none of the incentives usually prompting the soldier to high performance, with everything, indeed, against them, the Armenian elements, as a whole, earned the commendation of Nazim Pasha, the Turkish commander-in-chief, who declared in one of his despatches that the Armenian soldiers had performed their duty loyally and with courage.

Attempts by the Powers to ameliorate the political situation of the Armenian people were continued after the close of the Balkan War. Agreement with the Turkish Government seemed promising at the beginning of 1914, on the basis of an increased number of Armenian deputies for the Ottoman Parliament, and for the supervision of Ottoman officials in the "Six Vilayets" of Eastern Turkey-in-Asia by two European inspectors general to be selected by the Powers. There was also to be equal representation of Moslems and Christians on the councils of the vilayets of Van and Bitlis, in which districts the Armenian population was presumed to equal the Moslem. But the proposed reforms came to nothing. The Young Turk Government already had prevision of great events to come, and were temporizing in anticipation of developments.

The World War.—Between Oct. 29 and Nov. 5 1914, the action of the Young Turk Government resulted in war being declared on Turkey by Great Britain, Russia, France and Serbia. In committing their country to support of the Germanic Powers the Young Turk leaders saw, as they thought, the great occasion for recovering lost Turkish provinces and reëstablishing the Ottoman Empire on the widest foundations, with corresponding advantage to themselves. They believed that with Germanic support they were speculating in certainties. They resolved to use the fortunate opportunity thus presenting itself for making an end of Ottoman internal difficulties as they saw them. Chief among these was the question of the Christian people, of Asia Minor, the Ottoman Greeks and the Armenians, who cherished national aspirations incompatible with Ottoman sovereignty. The "Turkification" of the whole population of Asia Minor—the creation of a single homogeneous race for this great area—was the underlying purpose.

Policy of Massacre and Deportation.—How the policy for dealing with the Armenian part of the question took form we do not know. Probably Tal'at Pasha and Enver Pasha had as much to do with it as any—Tal'at at least is credited with its application—but they only sought to follow, on a greater scale, the example set in past years by 'Abdul Hamid. A preposterous and cynical scheme of compulsory colonization as part of the policy has been attributed to German theorists; but it was not even a mask except as affording greater opportunities for destroying the Armenian population. Described in a few words the policy was that of deportation coupled with extermination. The Armenian race was to be uprooted from the wide territories of Asia Minor beyond hope of continuance or return. From convenient areas those of the people able to march were to be deported to Mesopotamia and eastern Syria. Being an industrious and prolific race they might, in Mesopotamia, at least, do something toward creating a profitable, taxpaying province in place of one requiring incessant Ottoman outlay. Armenians from provinces too distant for deportation to be practicable were to be exterminated or driven to a fugitive existence.

Statistics of Armenian Population.—The following figures show the numbers and distribution of the Armenian race in Trans-Caucasia and Asia Minor, the destruction of which, or at least of the portion contained in Ottoman territory, was to be encompassed. In Russian Armenia the figures are those of the Russian census of 1916. For the Turkish vilayets they are, in the absence of any authoritative and reliable statistics, an exhaustive and impartial estimate for the period immediately before the war:—

Districts forming the Armenian Republic of Erivan:—Armenians, 795,000; Moslems, 575,000; other elements, 140,000; total, 1,510,000.

Areas claimed by Erivan, but claimed also by Georgia or Azerbäijän:—Armenians, 410,000; Moslems, 460,000; other elements, 36,000; total, 906,000.

The six Armenian Vilayets of Asia Minor in 1914.

	Bitlis.	*Diarbekr.*	*Erzerum.*	*Mamut el Aziz.*	*Sivas.*	*Van.*	*Totals.*
Armenians	185,000	82,000	205,000	130,000	200,000	190,000	992,000
Moslems	261,000	400,000	540,000	480,000	977,000	260,000	2,918,000
Other elements	19,000	78,000	15,000	2,000	108,000	133,000	355,000
Totals	465,000	560,000	760,000	612,000	1,285,000	583,000	4,265,000

The Policy in Execution.—It is unnecessary to follow in detail the execution of the infamous policy for the destruction of the Armenian population of Asia Minor. Suffice to say it was begun soon after the outbreak of war by concocting reports of Armenian revolutionary plots in support of the Allied Powers; and then, as far as possible, by a general disarmament of Ottoman Armenians. Though British operations in Gallipoli and Mesopotamia, and Russian operations against the eastern vilayets, kept the Turks occupied in a military sense, they did not prevent Turkish activity against Armenians. During the spring and summer of 1915, indeed, when the fate of Constantinople and Turkey hung in the balance and inhabitants of the Imperial City daily scanned the Sea of Marmora for signs of an approaching British fleet, the Young Turk Government prosecuted their Armenian policy with the utmost rigour. But when the Gallipoli operations had plainly failed, and the outcome of the war was thought to be no longer in doubt, a Turkish defeat in Russian Armenia, attributed by Enver Pasha to the Armenians, was revenged upon the race by massacres of even greater ferocity. From first to last they were organized and carried out systematically. Massacres on the largest scale took place at Bitlis, Mush, Sivas, Kharput, Trebizond—wherever, in fact, a considerable and more or less defenceless Armenian population existed. The people were butchered in masses, butchered in groups, drowned in the Black Sea and in rivers, burnt in buildings—killed by whatever processes were found most ready and convenient. Girls were placed in Turkish harems. It should not be supposed, however, that no resistance was offered, that the Armenian people sold their lives cheaply. Although supposed to have been disarmed, weapons remained, and on numberless occasions, in untold villages and towns, a hopeless resistance inflicted severe losses on the attackers.

Deportation, too, became an easy indirect means of destroying Armenian life. On the long routes of eastern Asia Minor by which movement took place; on the subsidiary roads leading to these routes; at the great concentration centres on which the columns of suffering humanity were directed, the Armenian people died of hunger, exhaustion, exposure, disease, in tens of thousands, perhaps in hundreds of thousands. Only a comparatively small proportion of those who set out reached the destination assigned them. The policy of transferring an Armenian population to Mesopotamia and Syria became in execution a wholesale means for destroying those who were despatched.

Estimated Loss of Armenian Life.—The Armenian policy of the Young Turks failed, however, in that part of Turkey-in-Asia lying between Erzerum and Bitlis and the Russian frontier. In this region, where the Armenian inhabitants were comparatively numerous, they were able to pass into Trans-Caucasia, or were preserved by the advance of the Russian armies. Within the stricken areas of Asia Minor, too, many escaped—many more than are generally supposed. Kurdish tribes gave friendly shelter; even Turks were not without compassion; the nature of the country, itself, afforded opportunities for escape and concealment on a large scale. And in the Anti-Taurus mountains were Armenian fastnesses unreached by Turkish forces.

Armenian estimates of the losses suffered by their people as the result of the Young Turk measures are liable to be excessive. It is in the nature of things that they should be. But if we place the loss of life directly and indirectly caused by massacre and deportation since the year 1914 as being in the neighbourhood of three-quarters of a million we cannot be very far from the truth. In addition are what may be called the legitimate losses of war, and these, in proportion to the manhood of the Armenian race, were enormous.

As regards the Armenian population, not only of Asia Minor, but of Trans-Caucasia as well, from first to last Russia is believed to have sent 160,000 Armenian troops from Trans-Caucasia to her battle-fronts in Europe, of whom less than 30,000 survived. For operations in Asia Minor she subsequently raised an Armenian volunteer army, and swept into it refugees from Turkish territory. From 1914 to 1921 Armenians were fighting incessantly in Asia—for Russia; for the French in Cilicia and Syria, where many thousands were embodied; and for themselves in Trans-Caucasia. Probably not less than one-sixth of the males of the whole race perished in warfare, in addition to loss by massacre and deportation.

Russian Policy.—A brief outline must now be given of the military operations of Tsarist Russia against the Ottoman Empire during 1914–6, for they deeply affected Armenia and the Armenians. For more than two centuries it had been the traditional policy of Russia to obtain possession of Constantinople and the waterway between the Black Sea and the Mediterranean. In the last 40 years she had seen her line of approach through the Balkan Peninsula made impracticable. Correspondingly her line of approach from Trans-Caucasia had gained immensely in importance. She had further established her naval supremacy in the Black Sea over any Turkish force that could be concentrated in those waters. With this as her policy, and in these circumstances, Russia, both openly and covertly, opposed all measures encouraging the development of Armenian national sentiment and aspirations, not only among the Armenian population under her rule in Trans-Caucasia, but also in Turkish Armenia. Tsarist Russia, in fact, desired Armenians in Turkey to remain a discordant disintegrating element in the Ottoman Empire, particularly in the eastern vilayets, until such time as she should be able to make further annexations. An independent Armenia, it thus appears, was impracticable during the existence of Tsarist Russia.

When war broke out between the Allied Powers and Turkey Russia recognized that the supreme opportunity for achieving her dearest ambition had arrived. Following the decision of the British and French Governments to send a military expedition to the Dardanelles, she made a formal request to her Allies that her claim to possession of Constantinople and the Straits at the conclusion of the war should be admitted in advance. A week later the Western Powers agreed to the proposal, and the destiny of the greatest strategical position in the world, and with it the destiny of Armenia, seemed to be definitely settled.

Russian Invasion of Turkish Armenia, 1914.—Russian troops crossed the frontiers on Nov. 4 1914, two days after the declaration of war, and advanced towards the great Turkish fortress of Erzerum. But the movement had no weight; it ceased after a few weeks of indecisive fighting, and the Turks launched a daring counter-offensive against Ardahan and Kars, in Russian Armenia. This reckless movement was ended, however, by the battle of Sarikamish (Dec. 29 1914 to Jan. 1 1915) at which, and at the battle of Kara Urgan in the subsequent retreat, the Turkish army was almost destroyed. In revenge for the disaster, attributed by Enver Pasha and the Young Turks to Armenian elements in the Russian army, and to support and intelligence given by Armenians generally, exterminatory measures against the Armenian population of Asia Minor were redoubled at the beginning of April 1915. It was at this stage that the British and French Governments issued (May 24 1915) a declaration that they would hold Ottoman ministers personally responsible for the massacres.

Armenian Troops in the Russian Armies.—Here it may be remarked that when Russia mobilized in Aug. 1914 for the World War, her Armenian troops, numbering, it is said, more than 120,000 men, were despatched to European fronts. When war with Turkey demanded great armies in Trans-Caucasia these troops were not available. But as a matter of policy Russia raised an auxiliary volunteer army of Armenians, including many thousands of refugees from Asia Minor, for service against the mortal enemy of their race. To these and other Armenians in the Russian armies of Trans-Caucasia—natives of the region, inured to its climatic conditions, between them familiar with every road and mountain path, and animated by every incentive to fierce and resolute combat—must be credited no small measure of the success which attended Russian arms against the Turks. Not without cause did Turkish leaders attribute their Caucasian disasters to their Armenian enemies.

Capture of Erzerum.—Stagnation followed on the Erzerum front for more than a year after the battle of Sarikamish. But during the spring and summer of 1915 a Russian army, operating in the neighbourhood of Lake Van, invaded and occupied the greater part of the Turkish vilayets of Van and Bitlis, peopled largely by Armenians. This southern campaign, however, had no serious importance except to distract Turkish attention and save an Armenian population. The one line of military advance from Trans-Caucasia into Asia Minor lay through Erzerum; and Russia was preparing for an unexpected spring upon this eastern bulwark of Anatolia. A great Russian army, including Siberian and Armenian troops, was concentrated within striking distance of the Erzerum position in the middle of winter. It advanced on Jan. 11 1916, and two weeks later had reached the outposts of the fortress, a march of some 80 m., with guns and supplies, through deep snow, at high altitudes, in temperatures often below zero. On Feb. 14–16 various commanding mountain forts, the main defences of Erzerum, some of them 9,000 ft. above sea-level, were taken by storm. The city was captured on Feb. 16—its fall a resounding disaster for the Ottoman Empire.

Invasion of Anatolia.—When the spring of 1916 came the Russians continued their operations westward, and by the end of July had captured the Black Sea port of Trebizond and the important military position of Erzinjan. They had reached a line about 30 m. west of Erzinjan, stretching from the Black Sea to the Euphrates and thence eastward to Lake Van and the Persian frontier, a line embracing the chief areas of Armenian population in Asia Minor. The line so held was nearly the same as that subsequently awarded by President Wilson as the western and southern frontiers of Armenia.

The Russian Collapse.—But this was Russia's farthest. She was weakening at home, where symptoms of upheaval were already appearing. On March 14 1917, a Provisional Government was proclaimed; the Tsar abdicated the following day; in September Russia was a republic, and on Nov. 17 Lenin and Trotsky seized the reins of power. The Treaty of Brest Litovsk, in which Germany imposed terms on her beaten and exhausted enemy, was signed on March 3 1918. The armed forces of Russia engaged in the war in western Asia lost their fighting value in 1917. The fleet at Sevastopol mutinied in June of that year and removed its officers; and the armies in Asia Minor were in process of disintegration at the same time. When the treaty of Brest Litovsk was signed these armies were only held together by the great personal influence of the Grand Duke Nicholas, viceroy and commander-in-chief in Caucasia, but had already voluntarily retired behind the Russo-Turkish frontier of 1914.

Treaty of Brest Litovsk.—In the Treaty of Brest Litovsk Turkish claims were not overlooked, in fact the treaty gave fulfilment to some of the wider ambitions which had developed in the Young Turk party. It provided, in effect, that between Russia and Turkey the frontiers should be those existing prior to the Russo-Turkish War of 1877–8; under this provision, therefore, the old provinces of Ardahan, Kars and Batum were to be returned to Turkey. Of these, Ardahan and Kars formed part of Russian Armenia, or Erivan.

Even prior to the signing of the Treaty of Brest Litovsk Turkey had been able to take advantage of the growing weakness of Russia. As early as Aug. 1916 she had recaptured the towns of Mush and Bitlis. But immediately after the signature of the Treaty she pushed her troops forward and between March 12 1918 and April 27 reoccupied in rapid succession Erzerum, Sarikamish, Van, Batum and Kars. The liberation of Turkish Armenia by Russia had failed, and the disaster involved the return to Turkish rule of a large part of Russian Armenia. The only hope for the Armenian people now lay in themselves—in whatever of wise prevision, unity and sacrifice they could command.

Federal Republic of Trans-Caucasia.—Steps in the right direction had, indeed, already been taken. The approaching collapse of Russia became apparent to Trans-Caucasian people early in 1917. On Sept. 20 1917 a Council of the Trans-Caucasian Peoples—of Armenia, Azerbaijan and Georgia—assembled at Tiflis, proclaimed Trans-Caucasia a Federal Republic, and formed a Provisional Government. When Turkey, after the Treaty of Brest Litovsk, proceeded to overrun western Trans-Caucasia this Government attempted to negotiate a peace but found the endeavour fruitless. Not only were the Turkish leaders obdurate but the republic had no real unity among its parts. Azerbaijan, with a Moslem population, though desirous enough of maintaining its independence, saw no great danger in Turkey recovering lost provinces at the expense of the Christian Armenians of Erivan; Erivan feared veiled annexation by Georgia under the guise of federation; and all three peoples were widely at variance upon questions of territory to which each thought itself entitled.

On April 13 1918 the Federal Republic broke off relations with Turkey and declared war, two days later the Turks occupied Batum, and on April 22 the Council of the Republic decided to proclaim its independence, but also to resume negotiations with Turkey for peace. With such waverings of policy the republic was likely to be short-lived.

The end came even sooner than was expected. On May 26 1918 the three states of the republic fell apart, each declaring its independence as a separate republic, and organizing a national Government of its own.

Armenian Republic of Erivan.—We now reach the point where the story of Armenia, hitherto the story of a dispersed people without a country, crystallizes into a story of an independent Armenian state—a state born to misfortune and bloodshed, surrounded by enemies, and inaccessible to its friends, a state whose survival and growth are matters more for hope than for confidence.

The territory of the republic of Erivan, excluding the districts in dispute with the adjoining republics of Georgia and Azerbaijan, comprised the two Russian provinces of Erivan and Kars, possessing an area of some 17,500 sq. miles. By the census of 1916 these provinces contained, in round figures, a population of 1,510,000 of whom 795,000 were Armenians, 575,000 Moslems, and 140,000 of various other races. But the effective territory and population of the Erivan Republic were even less at the time its independence was declared, for nearly one-third of its whole area was in Turkish occupation under the terms of the Treaty of Brest Litovsk. *De facto* recognition, however, was accorded the republic by the Allied Powers.

Outside the confines of the state so indicated lay other territories claimed by it, but claimed also by Georgia or Azerbaijan. Rather more than 2,000 sq. m. were thus in dispute with Georgia, and some 12,000 with Azerbaijan. The census of 1916 gave the disputed areas a population of about 900,000 equally divided between Armenians and Moslems. Part of the area claimed both by Erivan and Azerbaijan were the mountainous districts of Zangezur and Karabagh, peopled by Armenian highlanders, perhaps the finest representatives of their race. These, however, were separated from Erivan by an area in which a Moslem population predominated.

At best the territory occupied by the republic was an unfruitful region of treeless mountains and valleys containing little cultivated land, few resources, and a people reduced to the edge of poverty. Even in time of peace it had raised barely sufficient food for the needs of its thrifty population, but now when 400,000 refugees had poured into it, chiefly from Turkish Armenia, the question of supplies became more and more acute. The existence of the republic, indeed, was eventually affected by the difficulty of obtaining supplies, not only of food but of munitions and fuel.

But the republic was faced with many other difficulties, some external, others internal; the greater number immeasurably intensified by the country's unfortunate geographical position. Erivan was, in fact, an Asiatic Switzerland, though far more remote from the sea and more inaccessible. The only line of railway communication towards the western world ran through Georgian territory to the Black Sea port of Batum, the only roadway to the sea was also through Georgia to Batum. And

Batum at this time was in the hands of the Turks, and the Allies were still shut out from the Black Sea.

External difficulties were the active and veiled hostility of neighbouring states. Between Erivan and Turkey was the traditional hatred of Armenian and Turk, now inflamed to the desperation of a life-and-death struggle. Between Erivan and Azerbāījān was the standing enmity of Armenian and Moslem, given definite point by the massacre of Armenians at Baku some 15 years earlier, and of Moslems by Armenians during the months following the declaration of Armenian independence. There was also the acute question of territory in dispute, accompanied by incessant border fighting. Between Erivan and Georgia trouble, at the moment, was chiefly upon opposing territorial claims. Another hostile external influence was, a little later, exerted by Gen. Denikin and his supporters, who aimed at destroying the independence of the Caucasian republics and reuniting them to a resurrected Russia.

Internal difficulties, apart from poverty and questions of the supply of food, clothing, munitions and medical stores, were caused, also, by the absence of administrative experience among Armenian leaders and the sinister influence wielded by the Dashnakists. This Armenian secret revolutionary society held an extreme socialism; it was thus to a large extent in sympathy with the Bolsheviks of Russia. At the same time it stood for an aggressive military policy by the Erivan Republic and the extension of territory at the expense of adjoining states.

British Expedition to Baku.—Operations which might have had far-reaching results for Erivan and other Caucasian states led to the occupation of Baku in the republic of Azerbāījān, on July 28 1918, by a small British force. It had come from Mesopotamia through Persia, and thence up the Caspian Sea—a hazardous expedition intended to prevent, if possible, the despatch of German or Turkish detachments from Caucasia into Central Asia, and to open communications with the Caucasian republics. It had relied upon receiving local Armenian support at Baku, but this hope failed owing to the extreme war-weariness of the Armenian population. The Turkish troops which had already entered Azerbāījān received reënforcements early in September, and then attacked the town and compelled the British force to reëmbark on Sept. 15.

Armistice of Mudros.—The Armistice of Mudros, signed on Oct. 30 1918, ended hostilities between the Allied Powers and Turkey. Better days seemed now to be in sight for the Armenian race. Turkey was crushed, the Young Turk Government had fallen into disrepute, the chief leaders were in flight, and it was the avowed purpose of the Allies to free the subject races of the Ottoman Empire from Turkish rule. The Armistice contained conditions that speedily relieved the position for Armenians. The Straits were opened, Allied warships reached Caucasian ports and Allied and American relief work was begun. Trans-Caucasia was to be evacuated by Turkish troops, an Allied garrison placed in Batum and elsewhere if necessary, and Armenian prisoners-of-war and interned Armenians released forthwith. Another clause provided for Allied occupation, in whole or part, of the six Armenian vilayets of Asia Minor in case of disturbances arising.

War Between Georgia and Erivan, 1919.—The collapse of Germany and the Armistice of Nov. 11 1918, marking the complete victory of the Western Powers, seemed to promise the eventual creation of an Armenian state containing a majority of the race. But with Turkish occupation ended the Caucasian republics fell out more seriously among themselves. In spite of Allied efforts to prevent hostilities war broke out between Georgia and Erivan in Jan. 1919; fighting also continued between the Armenians of Karabagh and Moslems of Azerbāījān. At this time, too, the intrigues attending Gen. Denikin's movement went far to embroiling the republics. These unfortunate struggles did not, however, last long, nor were military operations undertaken on a serious scale, but the old causes of enmity remained, increased now between Georgia and Erivan by disputes regarding use of the Batum-Erivan railway, and the customs dues levied by Georgia on goods for Erivan.

Paris Peace Conference.—On Jan. 19 1919 the Peace Conference at Paris began its deliberations, from which, when Eastern problems could be reached, it was hoped that a satisfactory settlement of Armenian affairs might emerge. Each of the Caucasian republics was permitted a delegation to lay its claims before the Conference. Meanwhile the Supreme Council, acting as an executive body, despatched an Allied High Commissioner to Erivan to compose, if possible, the urgent differences between the rival republics.

Armenians of Erivan had agreed to join Armenians of Turkey in seeking the creation of a single Armenian state; the Armenian delegation at Paris therefore represented the whole Armenian race. The claim advanced by the delegation was, in brief, that to Erivan should be added the eastern districts of Asia Minor in which a considerable Armenian population had existed prior to 1914, and that these districts should include Cilicia as being the "Lesser Armenia" of mediaeval history.

But this comparatively moderate proposal bristled with difficulties, and traversed principles to which the Conference professed adherence. Ancient and mediaeval history offered feeble arguments for the recovery of territory from a race which could show effective occupation for the past 400 years. Nor did any juggling with ethnological figures assist the Armenian case, for the plain fact remained that in no vilayet of Asia Minor, even before the massacres and deportations, was there an Armenian majority over Moslems. The principle of self-determination by inhabitants would therefore, if applied, destroy Armenian claims.

The Armenian case stands, indeed, on firmer ground than doubtful historical sanctions and self-determination by a mosaic of local populations. Based on justice and high expediency it becomes a cause which no amount of theory can set aside.

Stated plainly the case for Armenia put forward by the delegation was that by race, language, faith, old history, services in the Allied interest, and barbarous treatment at the hand of the Ottoman Government over a long period, the Armenian people had shown themselves entitled to separate existence as an independent nation. And further, owing to their numbers having been artificially reduced by calculated and systematic massacre, justice required that their dead should be taken into account against the principle of self-determination within any Turkish territory to be allotted to an Armenian state. Expediency lay in the prospect that by the erection of an effective Greater Armenia a definite settlement of the Armenian problem would follow—a problem likely, otherwise, to remain insoluble. And yet more, that an Armenian state, extending from the Black Sea to the Mediterranean, would, with Allied aid, soon become a stable, self-reliant, civilized power in the midst of one of the chief danger-zones of the world.

The chief difficulty confronting the Armenian proposal was that the state to be created could not at first stand alone. It would require large financial and military support to set it on its feet and to maintain it during the earlier years of its existence—it was doubtful even if it could police its own territory at the outset. These difficulties were to be overcome, it was hoped, by placing the proposed state in the charge of a mandatory Power.

Throughout the year 1919 and the earlier half of 1920 the prospect of finding a Power who would undertake the onerous and costly task of mandatory grew less and less favourable. It had been hoped that America would accept the responsibility. The American people had shown much sympathy with the Armenian cause; politically America was disinterested and stood outside the jealousies of European powers; her prestige was great; her resources unimpaired; to the Armenian people she would have been their first choice as mandatory power. But the American Senate rejected the offer, fearing entanglement in Old World affairs. Great Britain, France, Italy, each felt unable to undertake the position—war had left them more or less exhausted; and their peoples would not incur the certainty of additional outlay of blood and resources. The Supreme Council

proposed that Armenia should be placed under the League of Nations; the League decided that the acceptance of mandates did not fall within its purpose. And when, at a later date, Armenia applied for admission to the League membership was refused her.

Treaty of Sèvres and Armenia.—The Treaty of Sèvres, imposed upon Turkey and signed on Aug. 20 1920, provided for the creation of an enlarged Armenian state and for the settlement of its boundaries. In Caucasia they were to be adjusted by direct agreement between the states concerned or, in failure of that method, by the Allied Powers. In Turkey they were to be defined by President Wilson as arbitrator; and the Treaty bound Turkey to accept his decision, but limited the area subject to award to the whole or parts of the vilayets of Trebizond, Erzerum, Van and Bitlis. The interests of Armenians remaining in Turkish territory were safeguarded under the Protection of Minorities clauses of the Treaty.

President Wilson's Award.—The award defining the Turkish frontiers of Armenia was given by President Wilson in March 1921. It assigned to Armenia the greater part of the vilayets of Trebizond and Erzerum, and the whole of the vilayets of Bitlis and Van—in all an area of about 30,000 sq. miles. The award gave the territory essential to the creation and development of a self-supporting state. It included the greater part of the eastern districts of Asia Minor containing the bulk of the Armenian population in Turkey. It provided a coastline for the state of about 150 m., and included the historic seaport of Trebizond on which north-eastern Asia Minor depends for access to the sea. And while fulfilling these conditions it brought within Armenian territory as small a proportion of Turkish Moslems as might be.

Wrecking of the Award.—But however admirable in itself, President Wilson's decision took Armenia little further towards actual possession of the territory awarded under the terms of the Treaty of Sèvres. The Peace Conference might assign the territory by treaty; the Turkish Government at Constantinople might accept and sign the treaty; and President Wilson might define the boundaries; but for Armenia to gain possession was another matter. It was on this difficulty—a difficulty to be overcome only by use of a great military force—that the fair prospect of an enlarged and independent Armenia was wrecked.

Even before the acceptance of the Treaty of Sèvres by the Constantinople Government the Turkish Nationalist movement had appeared in Asia Minor. Its chief purpose was to offer armed resistance to the execution of any treaty involving the transfer of Ottoman territory to Greece and Armenia. Whether the movement originated with the discredited Young Turk leaders or was a genuine movement recognized by them as a promising means to their own restoration to power, is not clear. But the movement grew rapidly in strength. Within a year the Nationalist Government, organized at Angora, was sovereign not only in Asia Minor, but had overshadowed the Constantinople Government and become the real rulers of the whole of Turkey. And as the movement gained in strength so the old Young Turk leaders reappeared—Tal'at Pasha, Enver Pasha, Kemal Pasha, and others—promoting an alliance with Bolshevik Russia; urging Pan-Islamic ambitions, and apparently forming with their followers the extremist Left wing of the Nationalist movement. To suppress this rival Government, even had there been no secret concord between the two, was beyond the power of the Government at Constantinople. Nor were the Allied Powers in a position to enforce a treaty by a great new war involving vast expense. Still less was any single Power willing to undertake the task. Beaten and dismembered though the Ottoman Empire was, there still remained in Anatolia a reserve of strength, which, in combination with the great military difficulties presented by the country, and aided by Bolshevik Russia, was able to defy and thwart the decisions of the Peace Conference.

Greece, indeed, her own territorial gains at stake, and supported by the Allies, commenced military operations against the Nationalists in May 1920; and it seemed probable that the Armenian cause might benefit. The republic of Erivan therefore prepared to send troops into the territory assigned her by the Treaty of Sèvres, and desultory fighting occurred. Turkish strength in eastern Asia Minor, however, was too great for the small force Erivan could spare from other fronts to have any prospect of success, and no actual invasion of Turkish territory took place. Meanwhile Greek armies encountered little resistance and occupied a large area of western Asia Minor. These operations, however, in no way crushed the Nationalist power.

In Feb. 1921, Greece undertook yet greater operations; this time unsupported by the Allies, and in defiance of their wishes. She aimed at destroying the Nationalist forces and capturing Angora; but by the end of March her armies were driven back, and she found that an offensive on a vastly greater scale would be necessary to ensure success. To this yet more serious campaign she definitely committed herself in the summer of 1921.

Bolshevik Invasion of Caucasia.—To complete this historical sketch, it is only necessary to glance more particularly at the unhappy events in Caucasia and south-eastern Asia Minor during 1920–1, for in this period the tragedy of the Armenian race seemed to have reached its climax.

The Bolshevik occupation of Baku, at the close of April 1920, ended the independence of the republic of Azerbāijān and established a Soviet Government in alliance with Moscow; it also brought Bolshevik forces into an area whence they could apply pressure to Georgia and Erivan. Bolshevik Russia and Nationalist Turkey were even now working together. Apart from strictly Bolshevik aims the common purpose existed of establishing direct communication between Russia, *via* Baku, and Nationalist Turkey. This could only be done through Erivan and Georgia by railway, or through Erivan by road; the republic of Erivan, in fact, completely barred both routes. In spite of Bolshevik propaganda in Erivan the people as a whole were strongly opposed to Bolshevism, and when in May Bolshevik forces in Azerbāijān attacked Erivan they encountered a vigorous defence, and were repulsed. Moscow now endeavoured to negotiate a treaty of alliance with Erivan, but the terms offered were too severe. They included:—the right of transit through Erivan by rail for Soviet troops; the cession of the disputed districts of Karabagh, Zangezur and Nakhichevan to Bolshevik Azerbāijān; and the control of the foreign policy of Erivan by the Moscow Soviet. Erivan refused, but in July was served with an ultimatum requiring it to evacuate the three districts just named.

The isolated republic had been in desperate straits for food, fuel for its railways, munitions and clothing for its troops; but supplies of munitions and uniforms, sent from England, reached the country just before the ultimatum was presented. For allowing the passage of these vital supplies through Georgia that republic, however, had insisted on retaining 20% of everything by way of toll.

While Soviet Russia applied pressure upon Erivan from the east, Nationalist Turkey did likewise from the west. The outcome was that the republic agreed to the occupation of Karabagh, Zangezur and Nakhichevan by Bolshevik troops, thus giving direct road communication between Azerbāijān and Nationalist Turkey. With the very existence of Erivan thus threatened and conscious that the same danger hung over their own country the Georgian people might have been expected to make common cause with their Armenian neighbours. The danger, however, seemed to them less; they had open communication by sea and could, they thought, await developments. They mobilized troops on their frontiers; but gave no active assistance to Erivan.

Fall of Republic of Erivan.—By Sept. everything was in readiness for the next act in the tragedy. At the end of the month a Turkish Nationalist army suddenly attacked and captured Olti on the western frontier of Erivan. In the meantime Bolshevik forces in Azerbāijān were massed along the railway skirting the northern frontier of the unfortunate Armenian Republic. An overwhelming Turkish advance was then made along the railway upon the great fortress of Kars in the heart of Erivan. Armenian troops checked the advance for a time, and

compelled a Turkish retreat, but it was only a temporary set-back; Kars fell, and the advancing Nationalists captured Alexandropol in November. Bolshevik risings broke out in the capital and other towns; the resistance of the republic collapsed, and the city of Erivan was speedily occupied by Turkish troops. At this stage a Soviet Government was set up, and the republic of Erivan became, in name, a Soviet Republic in alliance with Moscow. But even so it was a republic much reduced in area. In agreement with Moscow Turkey took possession once again of the districts of Kars and Ardahan, from which the Allied Powers had ejected her in Nov. 1918; and to this territory was added enough to bring the railway from Azerbaijan to Erzerum within Turkish possession. Only in the region of Karabagh was any vestige of Armenian independence preserved; there, indeed, the Armenian mountaineers repudiated Soviet Government and, so far, seem to have retained a precarious but independent existence.

With Turkish forces in occupation of Erivan, a state which had striven to form a Great Armenia by the acquisition of Turkish territory, massacre might have been foretold. It was hoped, however, that Soviet influence would prevent great bloodshed, but the hope had no real ground for existence. At Olti, Kars, Alexandropol, and then in the city of Erivan, massacres on a scale comparable only with those of 1915–6 took place; and if this policy was followed in the towns it was followed in the villages as well. The total loss of life cannot be estimated, but was certainly great. When the snow melted in the spring of 1921 thousands of Armenian corpses were revealed, heaped together, just as they had fallen in the closing months of 1920.

Cilicia and S.E. Asia Minor.—In Feb. 1920 Turkish Nationalist forces began serious operations against Cilicia, then in occupation by French troops as part of the French sphere of influence. They defeated various French detachments, captured the large town of Mar'ash, and there, and elsewhere in Cilicia as opportunity offered, resumed a systematic massacre of the Armenian population. The position was the more disastrous because, relying upon French protection for the future, a great immigration of Armenians into Cilicia had taken place; it was credibly reported, indeed, that some 20,000 of the race perished in south-eastern Asia Minor during the spring of 1920. At this stage the Allied Powers, who had recently decided that Constantinople should remain in Turkish hands, threatened to reconsider their decision unless effective Turkish protection were given to non-Moslem elements of the population in Asia Minor. The warning seemed to have some effect at the time, though later developments diminished its influence.

A definite Nationalist policy lay in the Cilician operations, however haphazard and casual they may appear. The idea had been broached, chiefly among Armenians, of creating a Franco-Armenian State in south-eastern Asia Minor—of, in fact, reviving the Lesser Armenia of history, and placing it under French protection. The hope that this scheme would mature was one of the influences which brought a large Armenian population into Cilicia in 1919. Nationalist operations in this region were designed to thwart the project by exterminating the Armenians, and involving the French in irritating and costly hostilities in defence of the territory. Warfare on a small scale continued during the greater part of 1920; for not only had the French their hands full in Syria, but they were anxious to avoid pushing matters to extremes with the Nationalists. They hoped, in fact, for an arrangement.

Siege of Hajin.—One of the most unhappy affairs of the Cilician War was the siege and capture of Hajin by the Nationalists. The town, a remote Armenian stronghold among the Anti-Taurus mountains, was held by its inhabitants against all Turkish attacks until Oct. 1920. Ammunition, however, ran out; expected relief never came; and in the end the town was stormed, and the greater portion of the population, numbering several thousands, perished in the usual massacre.

French Negotiations with Nationalists.—At the beginning of 1921 the French and the Nationalists came to an agreement by which, in return for important economic concessions in wide areas of Asia Minor, France was to vacate Cilicia. The National Assembly at Angora refused to ratify the agreement, on the grounds that it surrendered too much and obtained too little. They desired, in fact, possession of the port of Alexandretta which the French had retained. Negotiations, however, were continued. The hope that a Franco-Armenian State might be established in Cilicia had small prospect of realization unless a change should take place in French policy in these regions. (W. J. C.*)

ARMIN, FRIEDRICH SIXT VON (1851–), German general, was born at Wetzlar Nov. 27 1851. He took part in the war of 1870–1 and was severely wounded at St. Privat. After having occupied different positions on the General Staff, he was appointed in 1903 Director of the General Department of War in the Prussian War Ministry, and in 1911 General-in-Command of the IV. Army Corps at Magdeburg. During the World War he led his corps as a part of the First and of the Sixth Army; he was appointed in 1917 Chief-in-Command of the Fourth Army in Flanders, where he succeeded, in the spring offensive in 1918, in taking Armentières and the Kemmel Hill. At the close of the war he retired from the army.

ARMOUR, J[ONATHAN] **OGDEN** (1863–), American merchant and capitalist, was born in Milwaukee, Wis., Nov. 11 1863. Preparing for college in Chicago, where his father, Philip D. Armour (*see* 2.578), was a pioneer in the meat-packing industry, he entered Yale in 1881 but did not finish his course. In 1883 he entered the business of Armour & Co., and was made a partner the following year. After the death of his father in 1901 he became president and general manager of Armour & Co., which had been incorporated in Illinois in 1900. Under his guidance the business widely expanded. In 1918 in the United States alone it owned 14 slaughtering plants and 392 branch houses, with refrigeration capacity of 15,170 tons per day; the sum paid for live stock in one year was $517,951,026. The company was also engaged in the preparation of by-products, such as fertilizer, glue, soap and hair. Total sales grew from about $250,000,000 in 1910 to about $1,038,000,000 in 1919; total net income from $9,808,303 to $27,186,124. On Feb. 27 1920 an agreement with the Government, resulting from a threatened suit, was filed in the Supreme Court of the District of Columbia requiring Armour & Co. (as well as Swift & Co., Morris & Co., Wilson & Co. and the Cudahy Packing Company, all together popularly called the "Big Five" packers) to begin immediately and within two years finish the sale of "all their holdings in public stock-yards, stock-yard railroads and terminals, and their interests in market newspapers and public cold-storage warehouses, and forever to dissociate themselves from the retail meat business and food lines unrelated to meat packing." This would restrict them to wholesale business in meat, poultry, eggs, butter and cheese.

ARMOURED CARS.—The armoured car is a mechanically propelled vehicle equipped with protective armour and adapted as a fighting machine. Its first form consisted of a motor chassis with iron-plated sides fitted with loopholes for the crew to fire from. It rapidly developed into a miniature armoured fort on wheels with machine-guns and searchlights mounted in the most effective manner. This first type was liable to be put out of action by bombs thrown over the iron plating or from the windows of houses, and the iron plating was not proof against modern high-velocity rifle fire. The next improvement, therefore, was to place armour over the top. It was soon found that the requirements in the armament and arrangement of armoured cars were similar to the practice in the navy, and that, provided a car could be kept mobile, the next main essentials were a good range of observation and an all-round field of fire. This soon produced the turreted cars, with a single revolving turret and one Vickers machine-gun; and subsequently a type of car with two turrets abreast of each other, and containing each a Hotchkiss gun, was evolved. The advantage of a second gun in action was evident when it was found that bullets hitting the single gun penetrated the water jacket and thus rendered the gun useless. On the other hand the extra weight of the double turret placed a load on the chassis, which was already loaded

to its full capacity in order to carry armour that would be proof against modern fire.

The use of the armoured car is limited to the roads, although in some seasons in open countries it is possible to operate over large areas of terrain away from the roads. Obstacles can hinder the progress of cars to a certain extent, but with determined and skilful drivers, and well-trained crews, there are very few roads over which cars cannot be taken. In civilized warfare the maintenance of large armies necessitates roads being kept open for wheeled transport, and once the line formed by the fighting troops is overcome there is very great scope for the employment of armoured cars if placed under the control of a skilful and enterprising commander.

At the outbreak of the World War in 1914 several well-designed types of armoured cars were produced, but the enormous demands for motor transport on the part of all the combatants to equip their rapidly increasing forces prevented the production and development of armoured cars in sufficient numbers to do effective work at the beginning of the war. During the fighting in the autumn of 1914 there were many opportunities for their use, and a few naval cars and some small units did very useful work in France and Belgium, but when the armies on the western front settled down to trench warfare the blocking of the roads prevented the further effective use of armoured cars on that front. The armoured cars that had been made were then sent to the distant fields of operation in Egypt, Mesopotamia, East and South-West Africa, while the detachment of naval armoured cars that fought in Belgium were employed in Rumania and southern Russia, where they were almost the only representatives of the British army in those countries. During the periods in which the contending armies were stationary and gathering their forces for the decisive contest there was no scope for the armoured cars, owing to the shell-torn roads, trenches and barbed wire, but the value of the armoured protection, mobility and fire-power of the armoured car contained the basis of the idea which was to have considerable effect on the latter phases of the war. In the stationary warfare of trenches the deciding factors were machine-gun fire, wire and mud. The armoured car could withstand the first by its armour protection, and could return it on equal terms with its own machine-gun fire. If it could be made to cross mud and wire the attack could then meet the defence of trenches on more than equal terms. The best machine for crossing soft and broken ground at that time was the tractor with the endless steel belt, and by a compromise of the armoured car and the tractor the British tank was evolved (*see* TANKS).

Under peace conditions armoured cars form an essential part of most standing armies. As a means of policing the enormous areas in which the British army is responsible for keeping the peace the armoured car provides a unit which can be kept mobile, ready to move at the shortest notice, and can cover the greatest distances with the minimum fatigue and the maximum speed. It can only be exceeded in these respects by the aeroplane, but, unlike that machine, the armoured car unit can provide the armoured protection of a miniature mobile fort, equipped with machine-guns, searchlights, a plentiful supply of ammunition, food and water, that can hold its ground until a well-organized and well-equipped enemy has been assembled to meet it. In cases of civil disturbances, apart from armed rebellion, the armoured car provides a means by which the civil forces of the law can penetrate into the middle of a crowd in a way that would be impossible under ordinary conditions of police duty.

ARMOURED TRAINS.—In the earliest days of the application of railways to war uses, the idea presented itself both to inventors and to practical soldiers of utilizing the weight-carrying capacity of the railway and the pulling power of the locomotive for tactical as well as for strategic purposes. "Railroad batteries" figured in the American Civil War, and in the war of 1870; and armoured trains have appeared thereafter sporadically in most wars. Their utility, though it was confined within rather narrow limits, was unquestionable until the development of mechanical road transport. Nowadays, however, in countries where the rail system is sufficiently developed to give such trains real freedom of movement there exists an even fuller system of main roads on which armoured cars can operate, and in the World War period the fighting train has only figured in such theatres as those of the Russian civil wars, in which roads fit for heavy traffic are as a rule rarer than railways. As against the armoured car working on good roads the train must always suffer from being limited to certain tracks which are very easily interrupted by raids, air bombing, or artillery fire, and in the future, as cars of the four-wheel drive or caterpillar types improve, the freedom of movement of the armoured car cannot but increase even in theatres of war in which roads are few. Considered as a self-contained fighting unit, therefore, it is improbable that the armoured train will be of much practical utility in the future.

On the other hand, the old "railroad battery" considered as a form of gun-mounting possessed, and more than ever now possesses, many intrinsic advantages over other forms of mounting heavy ordnance for field warfare. In the well-laid bed of a railway track, organized to distribute heavy strains equably, such mountings have their firing platform ready made, and the power of the locomotive gives heavy artillery a mobility that otherwise it would lack. In this form, then, the train represents the battery vehicles of horsed or motor artillery. The central member is the heavy truck carrying the gun, and the others are arranged for ammunition and for the accommodation of the gun personnel. Light armour is frequently used for the protection of the vehicles against shrapnel bullets, and in some cases the gun itself is provided with a shield. These railway mountings are referred to under ORDNANCE.

ARMOUR PLATE (*see* 2.578).—The history of armour plate during the years 1909–21 differs from that of most other materials used in warfare, inasmuch as the period of greatest progress and activity occurred before the World War and was followed by a period of rest amounting almost to stagnation. The actual years of the war, which constituted a period of intensive culture as regards guns, shell, airships, aeroplanes, tanks, etc., added no stimulus to progress in the manufacture of armour plate. The efforts of British shipbuilders were devoted to the building of light, fast cruisers and destroyers for which there was urgent and immediate need, rather than to heavily armed battleships which would take three years to complete.

During the years immediately preceding the war, however, the manufacture of armour plate had made steady progress, and the improvement in quality was marked. There were no radical alterations such as the employment of a new alloy steel, or the introduction of a new process of manufacture; but in the application of scientific principles to the details of manufacture, and the various heat treatments through which the plate passes, immense improvements had been made and were apparent in the quality of the finished plate. In this connexion it can be recorded that a long series of trials have proved beyond doubt that British armour made immediately before the war was greatly superior in ballistic qualities to that manufactured in Germany, in spite of the fact that the process of armour-plate manufacture originally came from Germany. For example, a German 12-in. plate was found to be no better than a British 9-in. under the same test, while a German 10-in. plate was only equal to the British 8-in. The plates tested were taken from the ex-German battleship "Baden," and are therefore thoroughly representative of the German product.

TABLE I.—*British and German Armour.*

Thickness of plate in lb. per sq. in.	Index number representing limiting velocity of penetration	
	British	*German*
320 lb. armour	1,000	940
400 " "	1,000	less than 895
480 " "	1,000	less than 835
560 " "	1,000	915

In Table I the average limiting velocity of penetration for British plates is taken to be 1,000 ft. per second in each case;

the third column shows the comparative figures for German plates. The projectiles used at these trials were of similar mark and quality to those used in testing British plates of the same thickness.

In the case of the 400 and 480-lb. plates the actual limiting velocities were not reached, the projectiles, at the velocities indicated by the index figures, passing through the plates in a practically undamaged condition. Tests carried out on turret roof plates of 160-lb. and 200-lb. thickness also showed a marked superiority in favour of the British plates. These results may be accounted for to some extent at least by the fact that the manufacture of armour in Germany was a monopoly, and to all intents and purposes a State monopoly, whereas in Great Britain there were five rival firms of manufacturers and an Admiralty always asking for something better.

The necessity for improvement has been constant owing to the introduction of larger and more powerful guns—the 13·5-in. in the ships of the 1909–10 programme and the 15-in. in those of the 1912–3 programme.

Tables II and III, compiled from information contained in a paper read by Sir Eustace d'Eyncourt before the Institution of Naval Architects, show the increase in the thickness of armour on British and German battleships in answer to the challenge of the new guns.

TABLE II.—*British Armour* v. *German Guns.*

Programme	Guns on German ships	Main armour on British ships	Gun-houses
1906–7	11 in. 45 calibre	10 in. and 8 in.	11 in.
1907–8	11 in. 45 calibre	10 in. and 8 in.	11 in.
1908–9	12 in. 50 calibre	11 in. and 8 in.	11 in.
1909–10	12 in. 50 calibre	12 in., 9 in. and 8 in.	11 in.
1910–11	12 in. 50 calibre	12 in., 9 in. and 8 in.	11 in.
1911–2	12 in. 50 calibre	12 in., 9 in. and 8 in.	11 in.
1912–3	12 in. 50 calibre	13 in. tapering to 8 in. bottom and 6 in. top.	13 in.
1913–4	15 in.	13 in. and 6 in.	13 in.

TABLE III.—*German Armour* v. *British Guns.*

Programme	Guns on British ships	Main armour on German ships	Gun-houses
1906–7	12 in. 45 calibre	11·8 in. tapering to 6·3 in.	11 in.
1907–8	12 in. 50 calibre	11·8 in. tapering to 6·3 in.	11 in.
1908–9	12 in. 50 calibre	11·8 in. tapering to 6·7 in.	11¾ in.
1909–10	13·5 in.	13·8 in. tapering to 9 in.	11¾ in.
1910–11	13·5 in.	13·8 in. tapering to 9 in.	11¾ in.
1911–2	13·5 in.	14 in., 10 in. and 7·9 in.	14 in.
1912–3	15 in.	14 in., 10 in. and 7·9 in.	14 in.
1913–4	15 in.	13¾ in. tapering to 10 in.	13¾ in.

Any increase in the thickness of armour presents very serious problems to the naval architect on account of the great additional weight to be carried, and it is therefore of vital importance that the quality of the armour should be of the best. It is not only in regard to increase in thickness, however, that progress has been made. The superficial area of plates has also been increased, and plates measuring 15 to 20 ft. in length and 10 to 12 ft. wide are now not uncommon. Large plates are in fact a necessity in modern battleship construction. The striking energy of a large shell is so great that the resistance opposed to it must be distributed over as large an area as possible. As an example of the forces involved the striking energy of a 15-in. shell at a range of 10 m. is 30,000 foot tons, or in other words its energy is equivalent to that of an express train weighing 250 tons and travelling at 60 m. an hour. There is grave danger, therefore, that a small plate, even if it succeeds in stopping the shell, may be driven bodily into the ship. Moreover, it is as true to-day as ever it was that the weakest point in any armour is the joint. A heavy shell striking a plate near an edge or corner is liable to break off and carry away a piece of the plate with disastrous results, and it is therefore desirable to eliminate this risk as far as possible by reducing the number of joints to a minimum, that is to say by increasing the size of the individual plates. At the present time the size of plate capable of being placed on a ship is only limited by the carrying capacity of the railways.

No substantial alteration in the process of manufacture of armour has taken place since 1910, and the description given in the earlier article in this Encyclopaedia requires neither modification nor addition. In other respects, however, much has been learned, and some of the views held in 1911 require revision. For example, the statement that "plates sometimes vary considerably and are not of uniform hardness throughout" can scarcely be said to be true to-day, in spite of the great increase in size of modern plates over those made in the years previous to 1911.

It is impossible to discuss improvements in armour plate without at the same time taking into consideration the improvements which have been made in armour-piercing shell, and also the changes which have taken place in the nature of the attack. Conditions during recent years have been constantly changing. The introduction of capped projectiles, and the substitution of "unbacked" for "backed" trials, each presented problems for the armour-plate manufacturer. Moreover it has only been possible to solve these problems by the laborious process of trial and error, for there is no exact knowledge on the subject, and theories (of which there are many) have proved sadly misleading. For example, the action of the cap has been, and still is, a subject for discussion. It was for some time believed that the action of the cap was only effective at velocities over 1,700 ft. per second, whereas actual experiment has proved that it is equally effective at velocities of 1,000 ft. per second and even less. Constant alterations in the size, weight, and design, as well as in the quality of steel used in the manufacture of the cap, have further complicated the problem from the armour-plate manufacturer's point of view.

Interesting as the theoretical aspect of the subject undoubtedly is, there are at present too many unknown factors, both as regards shell and armour, to enable it to be regarded as an exact science; and recent experience has only served to confirm the statement made by an early authority, Maj.-Gen. Inglis, R.E., in 1880, that "in no subject that has ever been raised has mere opinion unsupported by practical experience proved so worthless as in this."

Bullet-proof Armour.—While there was a lull in the activity of armour-plate manufacture for naval purposes during the war, there was greatly increased activity in the production of light or bullet-proof armour. When the armies on the western front dug themselves in and the fighting resolved itself into trench warfare there was an insistent demand for some means of protection for the men who had to face rifle fire at close quarters. Innumerable suggestions were made and a vast number of experiments carried out with a view to producing a bullet-proof material of reasonable weight. The ordinary service bullet, consisting of a cupro-nickel (or in some cases a mild steel) case filled with lead, breaks up fairly easily on a plate of hard steel; but the Germans soon discovered that if the bullet is removed from the cartridge and reversed (*i.e.* so that the bullet travels with the base or blunt end in front instead of the pointed end) it did not break up but punched a hole in the plate.

Every effort was made to defeat this attack, but it was found that even with the use of the best quality of alloy steel available a minimum thickness of half an inch was necessary to stop the reversed bullet at short range. All sorts of materials were employed, but steels were found to be the most efficient, and of these nickel, chrome, manganese, vanadium, molybdenum and zirconium, both singly and in combination, were all tried. The best results, however, were obtained from nickel-chrome plates, sometimes with an addition of one of the rarer metals.

While these experiments were being carried out in England the Germans were busy endeavouring to produce something

more satisfactory than the reversed bullet which was only effective at short range. In this they were completely successful, and they produced the K or armour-piercing bullet. This consists of an outer envelope of mild steel of the same size and dimensions as the ordinary bullet. In the centre of the envelope is the bullet proper, made of hardened tungsten steel 30 mm. long, 6 mm. in diameter, and pointed at one end. The space between the envelope and the hard bullet is filled with lead. On striking a hard steel plate the outer envelope breaks up, but it and the lead lining appear to perform the function of a cap, and the hardened steel bullet perforates the plate.

At ranges up to 60 yd. with a good rifle, and more than this with a rifle in which the rifling has been worn, the armour-piercing bullet is not effective, owing to unsteadiness in flight, but at longer ranges nothing less than half an inch of the best steel is of any use as a protection against a direct hit at the normal. The action of the armour-piercing bullet, however, differs from that of the reversed bullet. The former is a clean penetration of the plate, whereas the latter punches a hole and removes a portion of the plate in the form of a small cylinder. Both at long and short ranges, therefore, a plate of at least half an inch in thickness was found to be necessary to give any real protection, and as plates of this thickness weigh 20 lb. per sq. ft. it was obvious that a soldier could not carry his own means of protection in addition to a rifle and the other impedimenta which he took into action. It became necessary then to devise some mechanical method of carrying protection, and the combined efforts of many minds in this direction finally resulted in that weapon of offence and defence which was afterwards known as a "tank" (*see* TANKS).

From the nature of the requirements it will be seen that the practice of the armouring of the tanks was by no means an easy one. In the first place the plates in an untreated condition had to be soft enough to be easily machinable, while after treatment they were required to withstand the penetration of the armour-piercing bullet and the punching action of the reversed bullet. This necessitated a very hard plate, but on the other hand it was essential that they should be sufficiently tough to prevent cracking or the breaking off of portions of the plate even when struck near an edge or corner. In addition the plates were to be capable of being riveted to the body of the tank or to one another, and finally they must be of the minimum thickness, as the question of weight was all-important.

These requirements were met by the use of nickel-chrome steel, which possesses properties of hardness and toughness to a remarkable degree. Steel containing 0·3 to 0·5% of carbon with 3 to 4% of nickel and 1·5% to 2·0% of chromium was largely used, and in some cases improved by the addition of one of the rarer metals.

In view of the work which the tanks were designed to carry out it was of the utmost importance that they should be perfectly bullet-proof, and it is perhaps not generally known that every plate was tested by firing trial against the German bullet before it was built into the tank. Under this severe but necessary test a very high degree of excellence in the quality of the plates was attained. The manufacturers had their own rifle ranges where the plates were tested under Government supervision before they were dispatched. (E. F. L.)

ARMSTRONG, SIR WALTER (1850–1918), British art critic and writer, was born in Roxburghshire Feb. 7 1850. He was educated at Harrow and Exeter College, Oxford. On leaving the university he became well known as a writer on art, and his judgment of pictures was considered of great value. From 1880 to 1892 he was art critic to various newspapers, among them being the *Pall Mall Gazette*, *St. James's Gazette* and *Manchester Guardian*. In 1892 he became director of the National Gallery of Ireland, a post which he held for more than twenty years. He was knighted in 1899. Sir Walter Armstrong was more especially an authority on the Dutch 17th-century and English 18th-century periods. He was the author of many works on art, of which the chief are: *Gainsborough and his Place in English Art* (1898); *Sir Joshua Reynolds* (1900); *J. M. W. Turner* (1901); *Sir Henry Raeburn* (1901) and *Art in the British Isles* (1909); besides *Lives* of Alfred Stevens, Peter de Wint, Gainsborough and Velasquez. He was also co-editor of Bryan's *Dictionary of Painters*. He died in London Aug. 8 1918.

ARMY (*see* 2.592).—In different sections which follow under this heading, the later history and organization of some of the powerful national armies which figured prominently in the World War are dealt with. In the articles on countries details of the post-war organization are given, and the object here is to explain the functioning of their armies in 1914–9.

I.—The British Army

Command and Administration.—In 1910 the British army was commanded and administered by an Army Council, a system first instituted on Feb. 6 1904. The constitution of this council was: the Secretary of State for War; the chief of the general staff (whose designation was altered in 1909 to that of "chief of the Imperial general staff"); the adjutant-general to the forces; the quartermaster-general to the forces; the master-general of the ordnance; the finance member of the Council; the civil member of the Council (later known—July 1916—as "under-secretary of State for War"); and the secretary of the War Office (as secretary). Outside the headquarters staff an inspector-general of the forces was appointed, whose duties were to review generally and to report to the Army Council on the practical results of the policy of that Council; and for that purpose to inspect and report upon the training and efficiency of all troops, on the condition of fortifications and defences and generally on the readiness and fitness of the army for war. On Aug. 2 1910 the duties of the inspector-general of the forces were divided between the inspector-general of the home forces and the inspector-general of the overseas forces (the general officer commanding-in-chief in the Mediterranean). Both appointments lapsed on the outbreak of war in 1914.

The above constitution of the Army Council continued until the outbreak of the war, after which it was varied from time to time by the following additions: the deputy chief of the Imperial general staff (Dec. 1915); the director-general of military aeronautics (Feb. 1916); the director-general of movements and railways (Feb. 1917); the surveyor-general of supply (May 1917). The director-general of military aeronautics, who was first appointed in 1913 directly under the Secretary of State, ceased to be a member on the institution of the Air Council on Dec. 21 1917. Another variation took place on Feb. 27 1918, when the permanent British military representative, British section, Supreme War Council of the Allied Governments, was added; but he again was removed on April 20 of the same year.

The assignment of duties varied somewhat under the successive Orders in Council, but the general principles were as follows: Duties in relation to operations were allotted to the chief of the general staff; those relating to organization, disposition, personnel, armament and maintenance, to the adjutant-general, quartermaster-general and master-general of the ordnance; those relating to the Territorial Force Associations, the Volunteer Force and War Department lands, to the civil member; finance duties, to the finance member; transportation, to the director-general of movements and railways; business relating to the commercial administration of army supplies, not under the control of the Ministry of Munitions, to the surveyor-general of supply.

In more detail the responsibilities of the military members of Council were as follows: The general staff dealt with the preparations for and the execution of military operations, including the estimates of forces required, the organization and establishments of these forces from the broader aspect, also with all matters connected with military intelligence and questions of staff duties, including training and education. The adjutant-general was responsible for all questions relating to personnel (except that of the Army Service Corps, Army Ordnance Corps, Army Pay Corps and Chaplains Department) and discipline, for organization, establishments in detail, mobilization, recruiting, discharges and for the control of the Army Medical Service. The quartermaster-general was responsible for supplies, transport, clothing and equipment (including personnel and organization), for movements, quartering, remounts and the Army Veterinary Service. The master-general of the

ordnance was responsible for armaments, the manufacture of ammunition and for the Fortifications and Works Department.

In the organization of the armies in the field a partitioning of responsibilities similar to that arranged among military members of the Council was adhered to though some modification was necessary because the staff in the field was organized under three principal staff officers only:—The chief of the general staff, the adjutant-general, and the quartermaster-general; the master-general of the ordnance had no direct representation at G.H.Q. The major portion of the latter's duties in the field came under the control of the quartermaster-general, while the engineer-in-chief (a special field appointment) absorbed such of the duties of the director of fortifications and works as were required in the field. The quartermaster-general in the field controlled the paymaster-in-chief, and had the assistance of the financial adviser to the commander-in-chief, while the adjutant-general in the field controlled the Chaplains Department. It is noteworthy that it was not until April 1917 that the director-general of movements and railways was appointed to the Army Council, involving the removal of these duties from the quartermaster-general's control; a similar change was effected simultaneously in the field armies by the addition to the commander-in-chief's staff of an inspector-general of transportation, independent of the quartermaster-general. Similarly, the appointment of a surveyor-general of supply, anticipated by that of an additional civil member of Council to supervise army contracts in Dec. 1914, took, for coördination purposes, from the control of the quartermaster-general, the master-general of the ordnance and the finance member, such functions as related to the commercial side of the business of supplying the army.

The military departments concerned retained responsibility for design, specification and testing as well as for research and experimental work. The director of army contracts was brought under the surveyor-general of supply, and later there was added the directorate of army priority which absorbed the branch known as "Allies' Munitions Requirements" from the Department of the Civil Member. A director of wool textile production was added in Dec. 1917, and in Feb. 1918 the Army Salvage Branch developed and was placed jointly under the quartermaster-general and the surveyor-general of supply. The only other appointment of interest is that of the military secretary. This office has always existed; at one time it was under the direct control of the commander-in-chief and later under the Secretary of State for War. The exact functions have varied from time to time. Broadly speaking, the branch, both in the War Office and at a G.H.Q. in the field, dealt with appointments and promotions of officers, and with honours and rewards for all ranks. Other changes which removed certain duties and responsibilities from the Army Council to newly formed ministries were effected by the creation of the Ministry of Munitions (June 1915), the Ministry of Pensions (Feb. 1917), and the Ministry of National Service (Oct. 1917). Thus, on its formation, the Ministry of Munitions took over responsibility for the supply of munitions, leaving the question of design to the War Office. About June 1915, however, the Ministry of Munitions became responsible for design in so far as part of chemical warfare and trench warfare was concerned, and in the following Oct. it took over responsibility for design in other directions. The director of artillery became indeed nothing more than the military representative of the War Office and the Front, responsible for making demands—affecting both design and supply—on the Ministry of Munitions.

In the original design for the British armies in the field, the inspector-general of communications held the status of a commander, but by a process of gradual absorption he eventually passed, except for defence duties on the lines of communication, under the command of the adjutant-general (for reënforcements and casualties) and the quartermaster-general (for supply and maintenance).

It is unnecessary to describe in detail the organization of army headquarters in India, but it should be said that, so far as Indian army troops coöperating with British troops in the various theatres were concerned, the system of command and administration was generally similar to that described above, the chief difference being that in India the medical, ordnance and military works branches were each of them independent branches, working directly under the commander-in-chief. As for the dominions, Crown colonies and protectorates other than India, it had been unanimously agreed at the Imperial Conference of 1909 that the organization of all the forces of the Empire should be assimilated as far as possible. In Canada there existed a permanent militia and an active militia, each serving on a three-year term of engagement. They were organized as 7 mounted brigades, 10 brigades of field artillery, 23 infantry brigades, with the necessary ancillary services. In Australia a Military Training Act had been passed, rendering liable for service in time of emergency all males between the ages of 18 and 60, and imposing compulsory training in the militia on all males between the ages of 18 and 26. The permanent force comprised only three field batteries, 13 companies of garrison artillery, with certain engineers and a nucleus of departmental services. This force, serving on a five-year engagement, and the militia forces, serving on a three-year term, were organized in both mounted and infantry brigades with establishments similar to those of the British army. In 1913–4 the militia comprised 23 mounted regiments, 22 batteries of field artillery and 50 battalions of infantry, with proportionate ancillary services. In New Zealand all males between the ages of 17 and 55 were liable for service in time of war, those between 18 and 25 undergoing training and those between 25 and 30 passing to the reserve. The permanent force (sufficient only for instructional purposes) serving on an eight-year engagement, and the territorial force, on a seven-year engagement, consisted of 12 mounted regiments, 9 batteries of field artillery, 9 batteries of garrison artillery and 16 battalions of infantry with the necessary ancillary services. In the Union of South Africa the permanent force on a five-year engagement consisted of five mounted regiments and five batteries of artillery. There were also a small coast-defence force and an active citizen force, serving on a four-year engagement, comprising nine mounted regiments, four dismounted regiments, three batteries of field artillery, 12 battalions of infantry and the necessary ancillary services. No other colony or protectorate maintained a force of any appreciable size, but all had some force of armed police or volunteers in some sort of military organization. In certain of the protectorates, such as East Africa, Nyassaland, Somaliland, Uganda, Gambia, Gold Coast, Nigeria and Sierra Leone, permanent coloured troops, officered by officers seconded from the regular army, were maintained for local service. In all the dominion forces the armament was in the main identical with that of the British army, the only important exception being that Canada in lieu of the Lee-Enfield ·303 rifle had the Ross of the same calibre. The latter was discarded early in the war.

Forces Available.—Until the end of the 19th century the British forces, always limited by the expense entailed, were maintained for the following purposes: (*a*) Garrisons of trained troops for the outlying colonies and protectorates (including India); (*b*) a force available for the prosecution of punitive expeditions, or for the maintenance of order in those colonies and protectorates or on their frontiers; (*c*) the first-line defence of the United Kingdom in the event of invasion. The South African War, however, of 1899–1902 proved such a severe strain on home military resources that assistance offered by the self-governing dominions was gratefully accepted; and the rendering of this assistance marks a definite and important step forward in the military organization of the Empire as a whole. Owing to the trend of European politics at the beginning of the 20th century, the purposes for which the military forces were maintained underwent a definite change, and the organization—still limited by the costliness of a purely voluntary system of service—was subjected to a series of reforms based on the following possible requirements: (*a*) a small striking force capable of taking the field in Europe at short notice; (*b*) garrisons for colonies and protectorates (including India) and reënforcements for the prosecution of punitive and other campaigns in connexion therewith; (*c*) the defence of the United Kingdom against invasion during the possible absence of the striking force referred to above. This change in policy, due to the possibility of intervention in a European war, involved the absorption in the striking force of the whole of the regular forces serving at home, and thus the provision of additional organized forces adequate for defence against invasion became a vital necessity.

During the years 1910 to 1914, therefore, military effort was concentrated on the organization of this small striking force of regulars (which received the title of "Expeditionary Force") and of the Home Defence Force of territorial troops. The focussing, at the outbreak of war, of the whole regular military energy and experience on a small expeditionary force, and the consequent neglect of preparations to make use of the untrained masses of the male population capable of bearing arms, led, however, to a temporary paralysis of the powers of expansion. The regular expeditionary force was permanently organized in its field formations of divisions; and up to the outbreak of the World War no higher formations, such as army corps and armies, had been definitely organized, although the staffs and headquarter units for a general headquarters and two armies (or

army corps) were detailed to be formed on mobilization. In addition the lines-of-communication troops provided were calculated to a minimum, which in practice soon proved inadequate. As regards personnel, the peace establishments of the units composing the force were, in the interests of financial economy, based rather upon the numbers required annually to provide the drafts necessary to maintain the strengths of the garrisons in colonies and protectorates than upon the requirements of the Expeditionary Force when it should take the field.

As must be the case with any army raised and maintained upon a voluntary basis and paid as economically as possible, a constant and large percentage of the individuals included in the home establishments were "immature," either because their training had only lately begun or because they had been accepted when still youths with a view to their gradual development; so that in order to put this Expeditionary Force in the field it was always necessary that there should exist reserves not only sufficient to make up the difference between peace and war establishments, but also sufficient to replace the "immatures" included in the peace establishments and to provide replacements for early casualties up to 10% of the force. But, in spite of continued and varied campaigning, the British army had never been called upon to replace any great number of casualties; and therefore the necessity for providing numerous trained reserves in excess of those required for first mobilization, although foreseen, was not sufficiently realized by the country as a whole.

The actual organization maintained, then, during this period was as follows: (*a*) The regular army at home, organized to place in the field, at very short notice, one cavalry division (four to five brigades), six infantry divisions (with a minimum of lines-of-communication troops), and certain coast-defence troops (for home defence). To meet the deficiences in personnel there existed: (*b*) the regular reserve, composed of men who had been fully trained by service in the regular forces; (*c*) the special reserve (known as "militia" until 1908), organized in units and composed of men who had merely received a recruit's training and subsequent annual trainings of 27 days in their special reserve unit, and certain skilled tradesmen who did not require and did not receive a military training (these were not organized in units). The special reserve units proper formed the infantry of the coast-defence garrisons. It was further proposed that certain of these special reserve units (known as "extra-special reserve units") should be used as units (not draft-finding) either on the lines of communication of the Expeditionary Force or to relieve regular units on foreign service in order that they might join the Expeditionary Force, should it be so desired. (*d*) The Territorial Force, organized in 14 mounted brigades, 14 infantry divisions and certain coast-defence troops. Being designed for home defence only, the peace establishment of the Territorial Force was intended to be that at which it would take up its defence duties in war. And not only was the strength of the Territorial Force seriously deficient, but much of the personnel were inadequately trained, and, moreover, included a large percentage of men who were too old or too young or physically unfit for active campaigning. The Territorial Force Reserve was so weak as to be negligible (661 officers and 1,421 other ranks on July 1 1914).

Other forces which existed or came into being during the years 1910 to 1914—which may be termed the preparatory period for the World War—were, in addition to the Territorial Force Reserve: (*a*) the Technical Reserve; (*b*) the Veteran Reserve. When these forces were first formed in 1910 they were intended to be part of the Territorial Force Reserve, but in 1911 they were reorganized, and the Territorial Force Reserve was relegated to its own force, the other two reserves becoming distinct formations, the Veteran Reserve being renamed the "National Reserve." Neither of these forces had any definite liability for service unless undertaken by individual members in some other capacity. The functions of the Technical Reserve were to supply expert and skilled workers to assist the national forces in time of national emergency. For this purpose there were registered a number of owner-drivers of motor vehicles, a few of whom were eventually attached to the Expeditionary Force, the larger number, however, being utilized at home. The "Voluntary Aid Detachment" scheme also was instituted as part of this reserve, and in accordance with the Geneva Convention. Originally designed to supply the personnel for "casualty clearing stations" it was finally used for the purpose of supplying personnel (almost entirely female) for military hospitals at home and overseas, each individual taking service on a personal engagement. The organization also provided and maintained a considerable number of hospitals and convalescent establishments at home.

Training of Youths.—Cadet units had been in existence for many years as a part of the old volunteer system, and were broadly divided into two classes: those raised and maintained by universities and schools, and those raised and maintained locally at the expense of individuals. On the formation of the Territorial Force the former class were formed into Officers' Training Corps, and in 1908 were removed from the jurisdiction of the Territorial Force Associations and came directly under the War Office. The latter units, however, were taken over by the Territorial Force Associations. The Officers' Training Corps existed primarily to provide officers for the special reserve and the Territorial Force; they were divided into senior and junior divisions by ages, the former being practically confined to the universities. Members of these corps could obtain a first certificate in either division, but the second, and qualifying, certificate could only be obtained in the senior division. The number of O.T.C. contingents in 1910 was 171 and in 1913, 182; but the numbers composing the units had increased in 1913 to 25,208. That efficiency was also growing is shown by the fact that, in 1910, 2,665 certificates were obtnined, and in 1913, 8,303—the attendances at Annual Camp in each year exceeding 10,000. In 1910 there were 340 officers commissioned direct from these Officers' Training Corps, and in 1913, 2,096.

During the war period the Officers' Training Corps were continued, and considerable use was made of their personnel in supplying the deficiency of instructors for the formation of the new armies and also in meeting the grave shortage of junior officers throughout the regulars, territorials and new armies. The normal work of the corps—more especially of the senior division in granting certificates and supplying officers for the Territorial Force and special reserve—continued throughout 1915; but at the end of that year those members who attained 18 years of age were called upon to be attested as privates, and were then immediately passed to the reserve. They were, however, continued as members of their O.T.C. until the age of 19, when they were summoned to the Colours. This continuation of their training enabled them to be rapidly brought forward for commissions, if duly recommended by their O.T.C.

The cadet units provided for the training of boys with a view to their eventually joining the ranks of the Territorial Force, and for this purpose there was a recognized affiliation between the cadet unit and the appropriate Territorial Force unit. In 1910 there were 39 such cadet units, comprising 53 companies, rising gradually to 258 units, comprising 848 companies, in 1914. During the war a very large increase took place, there being in 1915 312 units, comprising 1,007 companies, with a total strength of 41,108; which in 1919 had risen to 890 units of 2,464 companies, with a total strength of 102,500 cadets. Though by no means an Officers' Training Corps, the 28th Batt. of the London Regt. (Artists' Rifles) was in Dec. 1914 selected by the commander-in-chief to act as an officers' training battalion for the armies in France; it was withdrawn to the neighbourhood of general headquarters, and to it were attached for training all candidates for commissions from the ranks of the Territorial Force units in the field.

During 1916 the deficiency in officers became even more acute, and early in that year a cadet school was established in France at which N.C.O.'s and men selected from units actually in the field were trained with a view to their obtaining temporary commissions. Simultaneously the Army Council decided that in future—except in certain technical branches—no temporary special reserve or Territorial Force commissions would be granted to any candidate who had not passed through the ranks of a cadet school (latterly designated "cadet battalion") unless he had previous military experience as an officer. This necessitated the formation at home of a number of cadet battalions specially designed to prepare candidates for commissions. They must not be confused with the Officers' Training Corps of the cadet units normally existing in peace; in fact, members of both senior and junior divisions of the Officers' Training Corps were compelled to pass through these new cadet battalions before being considered for commissions.

Organization.—Certain reorganizations in the regular army itself took place immediately prior to 1914. The system of communication was greatly improved by the formation of signal

companies, Royal Engineers (telegraph, telephone, visual and despatch-riding). One such company was allotted to each division, the headquarters section being with divisional headquarters, and a section with each infantry or cavalry brigade headquarters, units maintaining their own signallers for internal communication. In the field artillery 2 howitzer brigades and 6 divisional ammunition columns were added, the result being that each of the 6 Expeditionary Force divisions was provided with a complete howitzer brigade of 3 batteries, in place of the brigade of 2 batteries which had hitherto existed. In consequence of these additions, an increased number of army reservists were required for mobilization; and to provide them a certain number of recruits for field artillery were taken for a short period of Colour service in order that they might be rapidly trained and passed to the reserve. In this way it was possible to reduce the number of special reservists of the field artillery, and the training brigades hitherto maintained for these special reservists became available to form the divisional ammunition columns on mobilization. The number of field-artillery depots was increased from 4 to 6. The infantry organization was also altered from 8 to 4 companies per battalion. This reorganization had not taken place in the Territorial Force when mobilization occurred, but was then introduced. A complete revision of the system of supply and transport in the field was also made. The divisional train system (organized in 4 companies, each composed of a technical headquarters and the baggage and supply wagons of units, manned by Army Service Corps drivers) was introduced, and the chain of supply to railhead was completed by the introduction of a mechanical transport supply column of 3-ton lorries for each division. This unit, plying between railhead and the refilling point, daily refilled the supply wagons of the train. The cavalry division did not form a train but was served by two mechanical transport supply columns of 30-cwt. lorries delivering on alternate days. The supply of ammunition was organized in a similar manner, the divisional ammunition column (horsed) refilled units and was itself refilled from railhead by a mechanical transport ammunition park (one per division). (For the FLYING CORPS, *see* the article under that heading.)

In the organization adopted for war the division was designed to be the tactical and administrative unit, self-contained in that it was composed of all arms (except the Flying Corps) and was provided with all the ancillary services required for its maintenance in the field. This system obtained throughout the British armies during the war, the divisions as self-contained units being allotted to army corps as occasion required, and these in turn to armies; the only deviation was in the case of the Australian and the Canadian army corps, in which the corps itself, once formed, remained intact and in certain respects became the "unit of administration."

The division in detail consisted of: headquarters (including the commander and staff, the commanders of artillery and engineer troops and the directors of medical, veterinary and ordnance services); 3 infantry brigades—each of 4 battalions, reduced in the winter of 1917–8 to 3 owing to shortage of personnel; 4 artillery brigades—each of three 6-gun batteries (three brigades were 18-pounder guns and one was 4·5-in. howitzers); one heavy battery and ammunition column—four 60-pounder guns, horse-drawn; one divisional ammunition column (carrying ammunition for all arms); 3 field ambulances—each comprising bearer and tent divisions; 2 field companies Royal Engineers (a third added later); one signal company R.E. (sections distributed to headquarters of divisions and infantry brigades); the divisional train (carrying baggage and supplies and executing all supply arrangements between refilling points and the troops themselves); one mobile veterinary section; one cavalry squadron (withdrawn almost immediately to reënforce the cavalry corps). Thus it had a strength (excluding details at the base at the rate of [illegible] of strength) of 585 officers, 17,488 other ranks, 5,592 horses, [illegible] guns, 24 machine-guns.

The organization of a cavalry division followed the same lines, but comprised 4 brigades each of 3 regiments, in place of 3 brigades each of 4 battalions in the infantry division. The strength (excluding details at the base at the rate of 10% of strength) was 439 officers, 8,830 other ranks, 9,815 horses, 24 guns (13-pounder), 24 machine-guns.

Administration of Personnel.—The record of services of all personnel (except officers) together with necessary personal details were kept track of through the "record offices." In these offices were filed the original attestation forms, on which all "casualties" affecting the rank and file (*e.g.* promotion, postings, transfers, alteration of original terms of service, wounds, rewards, punishments, and details of marriage, children and next-of-kin) were entered on receipt of the notification of the "casualty" from the unit concerned. This system continued in war as in peace. All such notifications in war, however, passed through the 3rd echelon of general headquarters of the theatre and were also entered on a special war army form which followed the individual throughout his service during the war period. By this means general headquarters could be kept informed of the state of their forces in bulk or detail and the War Office of the general strength of the armies. The careers of officers were followed in a somewhat similar manner, but certain War Office branches acted as record offices.

Payments to officers were made through agents (bankers), and special army cheques made out by an officer could be cashed within defined limits by field cashiers accompanying the troops. Payments to men were reported on "acquittance rolls" and entered in the personal pay book carried by every man. These payments—together with credits, counter-charges and claims received from any source or resulting from casualties reported to record offices—were brought to account by the regimental paymaster at home in charge of the accounts of the men affiliated to each record office. This system, prepared shortly before the outbreak of war and first tested therein, obtained for all theatres except India and Mesopotamia, and proved very successful—the maximum personnel engaged at any time being 1,942 directing staff (of whom 250 were females) and 44,676 subordinates (of whom 30,000 were females).

Mobilization.—Preparations for mobilization had received most careful and detailed consideration during the years immediately preceding the war; and it may be truly said, in respect of the Expeditionary Force, that when mobilization was ordered in Aug. 1914 everything was ready "down to the last gaiter button." These mobilization preparations were confined entirely to that Expeditionary Force; the embodiment of the special reserve and the Territorial Force being merely a calling-up of existing personnel and not in any sense a "mobilization." The stages in the prepared plan of mobilization were minutely followed, and comprised, first, the initiation of what was termed the "precautionary period," followed almost at once by that termed "general mobilization." The "precautionary period" scheme was based on the necessity for defending the United Kingdom against the possibility of invasion or raids—a primary danger in the case of an island power. For this purpose the rôle of the navy was of first importance; and defence was required for all harbours and dockyards called into use. The plan was briefly that all standing defences (artillery and its ancillary services of electric lights, etc.) should be immediately placed on a war footing—the personnel being completed by regular reservists who, on the first day of mobilization, joined the units detailed for standing defence duties. These units again were augmented by units of the special reserve and Territorial Force accustomed to train annually at the defences for which they were intended and which they actually manned at the outset of the "precautionary period." The mobile force associated with these defences was in the first instance formed of infantry and artillery units composing their peace garrisons, reënforced temporarily in many cases by detachments of serving personnel from units stationed farther inland and actually mobilizing. On the embodiment of the Territorial Force, certain of its units proceeded, according to programme, to their coast defences (known as their "war stations"), thus replacing units of the regular army temporarily forming mobile garrisons but actually destined for the Expeditionary Force; these Territorial Force units were sufficient not only to form the garrisons, but also to furnish small mobile columns. Later, certain of these units—chiefly those detailed for fixed defences—were in turn relieved by special reserve infantry units, who proceeded to their allotted coast defences or "war stations" after embodiment at depots, where they had shed their Expeditionary Force

personnel and absorbed any surplus regular reservists and sick and immature men of the mobilized regular units. In addition to the manning of the coast defences, certain vulnerable points —*e.g.* possible landing-places for small raiding-parties, cable landing stations, wireless receiving stations, vital railway bridges —required watching or protection at the inception of the precautionary period. This was undertaken as an additional obligation by the special service sections of the Territorial Force, each being allotted a particular war station. Those units of the Territorial Force not absorbed either at once or after relief by the special reserve units in coast defences, were assembled for training in their infantry divisions and mounted brigades; and preparations were completed for their rapid conveyance to any threatened point.

In actual fact a slight variation from the original scheme was made for a few days in respect of the disposition of the 4th Regular Division of the Expeditionary Force. This division, whose normal peace stations were in Woolwich, Shorncliffe, Dover, Chatham and Colchester, was ordered on the third day of mobilization to send small forces of infantry and artillery to Norfolk, Yorkshire and Edinburgh. Its headquarters were later moved to Bury St. Edmunds, and took over for some days the command of the east coast (excluding coast defences), until a Territorial mounted division was sufficiently organized to release the 4th Division for the Expeditionary Force in France. Similarly, the 6th Division from Ireland was brought over to England and assembled as a support to the Territorial formations guarding the east coast. This division, an integral part of the Expeditionary Force, was retained at home for this defensive purpose until the beginning of Sept. and only then followed the Expeditionary Force, joining it on the Aisne. General mobilization was, therefore, really confined to the regular units comprising the Expeditionary Force.

To deal first with personnel. As a constant preparation for mobilization, each unit during peace compiled twice yearly a mobilization form, showing the personnel actually available with the unit, less those required for duty elsewhere and those immature or insufficiently trained for the field. This form was passed to the record office concerned, which, after stating the number of reservists detailed for the unit and its first reënforcements (which invariably accompany it overseas), and any deficiency or surplus of reservists, passed on the form to the War Office for investigation and information. The only action taken in the War Office was to detail the requisite number of officers from the reserve of officers and special reserve. The proclamation of mobilization and simultaneous issue of posters and individual notices summoned all reservists to rejoin the Colours—those of cavalry and artillery to allotted depots; those of infantry to regimental depots, where they were clothed, armed, equipped and dispatched as required to units, the residue remaining at depots for incorporation in special reserve units in course of embodiment. Those of other arms rejoined their units direct, there to be clothed, armed and equipped; any surplus or deficiency being adjusted by their corps depots, where the surplus unallotted reservists rejoined. As regards *matériel*, each unit of the Regular Expeditionary Force (with the exception of certain mechanical transport units of the Army Service Corps) possessed the mobilization vehicles, arms and equipment required to pass from peace to war scale; and it was merely a question of issue and taking into use. As regards horses, the whole system had undergone revision only just in time for actual mobilization. This system was that commands made a classified census of suitable horses available among the civil population. Any surplus over and above that required by units mobilizing in one command was re-allotted by the War Office to meet deficiencies in other commands—*e.g.* the Aldershot command, which has practically no territorial area, obtained most of its horses from the London district, which mobilized very few troops. The system involved sending for the horses, but the loyal coöperation of inhabitants in voluntarily bringing their horses to named centres to a certain extent overcame this defect. Certain large firms had for some years received annual subsidies under a contract to provide on emergency a given number of horses of specified classes suited to military requirements.

The War Period.—Owing to the special conditions of warfare which prevailed from 1914 onwards, to the progress of inventions, and to the variety of theatres in which operations took place, the standard organization of the original Expeditionary Force proved inadequate to meet the various requirements. It is, however, noteworthy that the structure of the infantry division—the main basis of organization—remained substantially intact, though the strengths and the proportions of arms and services underwent modification, according to changing conditions and the special needs of certain theatres. Thus, to the divisional organization were added, for example, an employment company and a salvage section.

Royal Engineers.—In the later stages of the war the need—in connexion with artillery-ranging—for more accurate ground surveying than was afforded by the field-maps became evident. The three field survey companies—employed prior to mobilization by the Board of Agriculture and Fisheries on the continuous survey of the United Kingdom—were therefore expanded into field survey battalions, France receiving one per army and other theatres a due proportion. These included specialist sections termed topographical, map, observation, sound-ranging and meteorological.

When mine warfare was added to trench warfare above ground, 25 special "tunnelling companies," recruited from coal-miners, were formed, each with an establishment of 14 officers and 397 other ranks. This was later raised, in the case of all but 5 companies, by 4 officers and 223 other ranks per company, by the attachment of infantry working parties.

Artisan works companies to the number of five were formed in France for the construction of hutting and other engineering work. Eleven forestry units, for the purpose of obtaining timber in France, were raised, and in addition a considerable number formed in Canada were employed in France, Scotland and Wales. Seven army tramway and foreway companies were formed in France to construct, maintain and operate trench tramways and light railways, and these eventually became transportation (R.E.) units. A "special works" unit (Camouflage Park) was formed in 1916 and operated throughout the armies. A small inundation section was formed in France in 1918.

Chemical Warfare.—After the German gas attack at Ypres in April 1915 a start was at once made to select, organize and train the personnel who were to be concerned with the use of this new lethal weapon. The first special company of the Royal Engineers was formed for the purpose in July 1915, and numbered 186, and three other companies were in existence by Sept. of that year, taking part in the battle of Loos. Rapid progress continued; during the winter 1915–6 the 4-in. Stokes mortar and an improved flame-thrower were developed, and in Oct. the special companies were expanded into a special brigade R.E., which was composed of a special (cylinder) company R.E., with an establishment of 8 officers and 250 other ranks, a special (mortar) company R.E., of 18 officers and 310 other ranks, and special sections R.E. (for flame-throwers) which, however, were never fully equipped or up to strength, the use of this weapon being soon abandoned. During 1917 this organization was again revised, and each of the five armies then in existence in France was provided with a headquarters special company R.E.—the various technical companies being allotted as required by the tactical situation.

The above was the organization for offensive action. Defensive measures against gas were first organized by the director-general of the army medical services; and in June and July of 1915 specialist officers were appointed to the headquarters of each army, where anti-gas schools were established. These officers were at first called "chemical officers," then "gas officers," and finally "chemical advisers." In March 1916 the defensive measures were taken over by the director of gas services for coördination with the offensive measures, and gas officers were appointed to all divisional headquarters where anti-gas schools were established. The special brigade R.E. also provided non-commissioned officers to infantry brigades for the purpose of checking the fitness or otherwise of the respirators and for supervising the general state of gas defence. In March 1917, chemical advisers were appointed to each corps headquarters. The gas services eventually expanded to a total of 490 officers and 6,875 other ranks.

Royal Artillery.—In the original Expeditionary Force the ratio of guns to infantry was approximately 6 per 1,000 rifles, but as the war progressed so did gun-power show a marked increase; and whereas in Aug. 1914 Royal Artillery personnel throughout the world totalled 92,920, by Aug. 1918 it had reached 548,780. Taken in detail the horse artillery made but slight increase, the number of batteries rising from 26 to a maximum of 28 in 1918; field artillery increased from 153 to a maximum of 722 batteries in 1915. This number, however, was subsequently reduced to just over 600 6-gun batteries by the assimilation of a certain number of 4-gun batteries. A considerable reorganization took place later when the field artillery brigades were reclassed as "divisional" and "army." In the Royal Garrison Artillery, which manned the medium and heavy guns and howitzers as well as the few mountain batteries, the number of heavy batteries rose from 12 to a maximum of 100 in 1916; siege batteries from 3 to a maximum of 425 in 1917; mountain batteries from 9 to a maximum of 17 in 1918. Anti-aircraft sections, non-existent in 1914, reached a maximum of 275 in 1918. Trench mortar batteries, first formed in 1916, reached their maximum of 142 in 1917.

Machine-Gun Corps.—In the autumn of 1915 the formation of the Machine-Gun Corps was decided upon. Originally consisting in

separate companies, the corps was reorganized in the winter of 1917–8 on a battalion basis. Eventually one machine-gun battalion was attached to each division, and other battalions were army troops. A battalion comprised 4 companies, and a company consisted of 4 sections each of four guns (total 64 guns). A portion of this corps eventually became the nucleus of the Tank Corps.

Tank Corps.—In June 1916, the heavy section of the Machine-Gun Corps in France was organized in six companies as the nucleus of the Tank Corps. Each company consisted of 4 sections, each of 6 tanks, three "male" and three "female," with one spare tank per company. The crew of a tank was one officer and seven other ranks. In Sept. of the same year expansion was decided upon. An administrative branch was to be formed in England and a fighting branch in France, consisting of 4 companies designed to become 4 battalions as the tanks became available. At the same time 2 companies were formed in England with the intention of their development into 5 battalions. By Nov. 1916, the first 4 battalions in France were grouped in 2 brigades, and in April 1917, the 3rd brigade of 2 battalions was transferred there from England. Expansion continued, and in June 1917, the title of "Tank Corps" was definitely bestowed on the corps.

In April 1918—after various vicissitudes and delays, due sometimes to difficulties of manufacture and sometimes to shortage of personnel—a portion of the corps was formed into armoured car battalions; and at the time of the Armistice plans were in hand for an establishment of 6,000 tanks in 1919. The original Tank Committee which had handled the design and manufacture of tanks was replaced early in 1918 by a Tank Board including official representatives of the Ministry of Munitions, Admiralty and War Office and individual experts, thus ensuring for the new arm a concentration of expert naval, military and industrial knowledge.

Medical.—On the outbreak of war steps were taken to prohibit the export of drugs and to encourage the manufacture in Great Britain of certain drugs which before the war were largely imported from Germany. Elaborate arrangements were made to meet very large demands for medical and surgical stores, and there was no lack of the essential remedies and appliances required for the treatment of the sick and wounded. The Army Medical Stores at Woolwich were expanded and depots were established throughout the country for the supply of medical stores to home hospitals. The use of certain acids, etc., for medicinal purposes was either stopped or restricted and substitutes employed so that these substances might be available for the manufacture of explosives. Stocks of quinine were commandeered to meet heavy demands, and during the early part of the malarial season of 1917 the average monthly issues of this drug were over 5½ tons. A total of 1,088,000,000 tablets of compressed drugs were supplied, and some 34,000,000 doses of various vaccines and sera were issued for the prevention and treatment of disease. Practically all the vaccines were manufactured in the laboratory of the Royal Army Medical College. An army spectacle depot was established in London for the supply of spectacles, etc., to the troops, and this depot eventually supplied all the artificial eyes and ophthalmological apparatus required. Over 350,000 pairs of spectacles and 22,386 artificial eyes were supplied, and 528 X-ray outfits of various types were issued. Splint-making shops were established in France, Egypt and Salonika, the output of which was supplemented by the supply from Great Britain to the armies in the field of 1,675,000 standard splints. Enormous quantities of surgical dressings were issued during the war, including over 108,000,000 bandages, over 87,700 m. of gauze and over 7,250 tons of cottonwool and lint. At the beginning of Aug. 1914, hospital accommodation in the United Kingdom amounted to approximately 7,000 beds, distributed in some 200 hospitals of varying sizes. On the mobilization of the Territorial Force the hospital accommodation was increased by 11,960 beds in 23 general hospitals (subsequently increased to 25) which were rapidly established in buildings which had been earmarked previously for the purpose, chiefly in university towns. The permanent military hospitals, with the 23 Territorial Force general hospitals, formed the nucleus of the war hospital accommodation in the United Kingdom. This accommodation was expanded as occasion demanded by means of hospitals organized by Voluntary Aid Detachments or private effort, by the conversion of asylums, poor-law institutions, and other large public and private buildings into temporary military hospitals, and by the allocation of beds in civil hospitals and the erection of large hutted hospitals in the various training centres. At the time of the Armistice the hospital accommodation in the United Kingdom had been expanded to a total of 364,133 beds in 2,426 hospitals and there were then 333,074 patients in these hospitals. During the period Aug. 28 1914 to July 31 1919 there were received from overseas and distributed to hospitals in the United Kingdom 2,640,650 sick and wounded. One hundred hospital ships was the maximum number ever employed, and 56 fully equipped and extemporized ambulance trains were in use at home. In 1914 the strength of the R.A.M.C. was 1,068 officers, 3,895 other ranks, 463 nursing sisters; while at the time of the Armistice its strength had risen to 13,045 officers, 131,361 other ranks, 12,769 nursing sisters, and 10,897 V.A.D.'s

Dental Service.—Prior to the war no dental treatment was provided for in the military organization, necessary work being carried out by contracts with civil dental surgeons. The reduction of the standards for enlistment necessitated by the war resulted in a small organization being formed, and later the introduction of compulsory service increased the needs for dental treatment enormously, and the lack of sufficient army personnel to cope with the work at one time seriously affected the preparation of drafts for overseas. In 1918 it was calculated that 70% of slightly over 1,000,000 men at home required dental treatment before being dispatched overseas, and in July 1918 it was found necessary to call up for service all civil dental surgeons who were liable and to employ them professionally with the troops. The number of dental surgeons commissioned for professional work rose from 36 in 1915 to 850 in Nov. 1918.
